The supply canal, which has a length of 4,920 ft., is of rectangular cross-section, 14.76 ft. wide and 8.36 ft. deep. For 410 ft. of its length it is of tunnel construction. The whole canal is of concrete. It is provided with several overflow sluices for conducting away surplus water, which runs into the canal from the sides of the mountain. Two overflows are placed near the dam. The whole canal may be cut off by three sluice gates which work vertically against rolls. To the sluice gates at the sides of the canal are attached ⅛-in. sheet-iron strips or angles, which are pressed against the wall by the water, thus making a close joint. The canal empties into a small basin at the power house and the bottom of this basin lies 26 ft. above the machine room floor level of the plant. From one side lead to the turbines four penstocks 5.5 ft. in diameter, three of ⅜-in. thick riveted steel plates.

The erection of the power house on the mountain slope was accomplished with difficulty, owing to the restricted area and the frequent flooding of the building site. The power house, which is 147

Fig. 1.—View of Interior of Power House, Showing Wheels and Generators.

ft. in length and 47½ ft. in width, has space for five hydro-electric units, four of which are at present in place. The foundations are of concrete, as is also the floor, which is surfaced with tiles except along the dynamos, where a roomy trench for cables to the switchboard is covered with checkered steel plates, as shown in the illustration. A crane of 15-tons capacity is in position. The roof is of steel construction with tiles resting on wooden sheathing.

The turbines are horizontal and of the inward-flow radial type and furnish 700 hp with 60.3 ft. fall and 250 r.p.m., while at high water with a fall of 43.5 ft. their capacity is reduced to 500 hp. The turbine shaft is 23 ft. above low water level and the turbines are provided with Jonval draft tubes, the ends of which remain well submerged even at low water. There are for each turbine two such draft tubes 3.6 ft. in diameter symmetrically placed axially with the shaft, while between them is the turbine chamber, into which empties the penstock. All these portions are of riveted steel plates.

On the shaft of the turbines are mounted two distinct water wheels of equal size, each 2.6 ft. wide and of 4.5 ft. in diameter and each discharging into its own draft tube. They are of cast iron and have five rows of blades or cells in one casting. A hub for each water wheel is mounted on the shaft and the blade ring is bolted to this. The four outer rows of the blade ring are calculated for normal flow, while the more numerous blades at sharper angles of the inner or fifth row are for high or low water. A sliding jacket of steel plate construction operated from a mechanical servo-motor by means of bevel, screw and nut, regulates the admission of water. The Piccard governing system is in use on each turbine.

The dynamo shaft is connected with the turbine shaft by an elastic insulating coupling of the Raffard system. The dynamos of the Oerlikon three-phase alternating inductor type, develop 7,500 volts with a phase voltage of 4,330, since the armature winding is star-connected. The current strength is 50 amp. per phase. At 250 r.p.m., with 20 poles, the frequency is 50 per second. The magnet wheel frame is of cast steel and is bolted to a cast-iron hub of six spokes. The outside diameter of the wheel frame is 6.19 ft., its width is 3 ft., and its thickness 5 in. Twelve laminated poles are bolted by dove-tailing to the circumference of the magnet frame, or a total of 24, the members of each pair being placed opposite and 17

FIG. 3.—VIEW OF DAM AND SUPPLY CANAL.

in. apart. The height of each pole is 5¾ in., the width 9 in. and the thickness 8¾ in. The outside diameter of the magnet field is 7.18 ft.

In the space between the opposite poles are built up in two parts the magnet coils, connected in series, in copper bars 2½ in. x 3/32 in., to a total number of 160. The weight of the entire revolving portion of the dynamo is 7.0 tons, while the weight of the magnet copper is 1¼ tons.

The dynamo frame which carries the inductive windings, is in two parts, a bottom and an upper section, and twelve large openings are provided in the outside periphery, as shown in the illustrations, for ventilation. This frame is in cross-section a trapezoid of a thickness of 12 in. and a width of base of 2.9 ft. The outside diameter is 10.3 ft.

Like the magnet wheel, the armature is arranged in corresponding parts. The segments of each part are held together by bolts and two cast-iron rings, one of which is removable. The bore of the magnet field is 7.23 ft., while the depth is 6½ ft. and the width is 10 ft. Each side of the armature has 72 slots, each of which contains two coils of machine-formed windings insulated by mica and secured by fibre wedges. Each coil contains 33 turns of two parallel conductors of ⅛-in. wire. The coils of each phase are connected in series, corresponding to the phases of the armature parts.

The weight of the armature copper is .6 ton, and the weight of the

FIG. 4.—SUPPLY CANAL AT TUNNEL ENTRANCE.

entire stationary frame, including armature, is 15.4 tons. The normal exciter current is 90 amp., with a power factor of 0.8 and 50 amp. per phase. Under these circumstances the voltage drop is 25 per cent. Running free the exciter current is 56 amp., while on short-circuit it is 31 amp. At normal load and $\cos \phi = 0.8$, the efficiency is 93.5 per cent. The loss is divided as follows: Friction loss, 24,300 watts; heat loss in the armature, 10,300 watts; heat loss in the magnet wheel, 1,810 watts, or a total loss of 36,410 watts. The exciter dynamo field is bolted to a bracket of the bearing, its armature being on the overhanging end of the shaft. It is a four-pole, shunt-wound machine and develops 3,600 watts at 30 volts.

On account of the great number of distribution wires and the limited space at the north wall, a two-story switchboard has been erected in closet form. The upper portion contains the measuring apparatus and is reached by iron stairways, the floor, which serves as the roof of the lower portion being 9 ft. above the main floor. The switchboard is 21.9 ft. long and is 13.9 ft. deep from the lower face to the wall and 4.8 ft. deep from the upper face to the wall. This part is 7.3 ft. in height. The whole switchboard is of steel construction and the portion bearing the measuring apparatus is faced with marble and is divided into five panels, four for machine groups and outside circuits, the middle panels bearing the general voltmeters. Behind the upper portion are the distribution wires and lightning arresters; the lower portion, which may be entered from either end, and which is enclosed by finely perforated sheet iron almost as transparent as gauze, is divided by an aisle lengthwise and contains high-tension switches for the machines, the machine fuses, rheostats, auxiliary transformers, cable connections from the machines and cross connections. The portion against the wall contains the fuses of the outside circuits, and over the aisle are arranged the high-tension switches for these circuits, being operated by levers from the balcony, or operating platform. All the switches and fuses used are of special construction, and so made that at the moment of breaking in a chamber the admission of air and the creation of an arc are prevented. The high-tension safety fuses are constructed on the same principle. They are vertically mounted and closed at the top and in case of a short-circuit the gas escapes through a comparatively small opening at the bottom.

The cross connections are of aluminum. All wires are carried on porcelain insulators.

Four main distribution branches of high-tension wiring lead from the power house at Sant Mortier. One proceeds to St. Claude, 16.2 miles in length, of two circuits, of three 8-mm. diameter conductors each. A second to Nantua is 12 miles in length, of which the first 5.5 miles are of 8-mm. wires, while the remainder to Nantua are of 6 mm. diameter, with a branch from the end of the first 5.5 miles to Viry of 4 mm. From different points on the latter circuit small branches lead to Oyonnax, Belignat, Montreal and Marchon, each of three-wire 4-mm. diameter. The third main is exactly 5 miles in length and leads to Arinthod and is of three 4-mm.

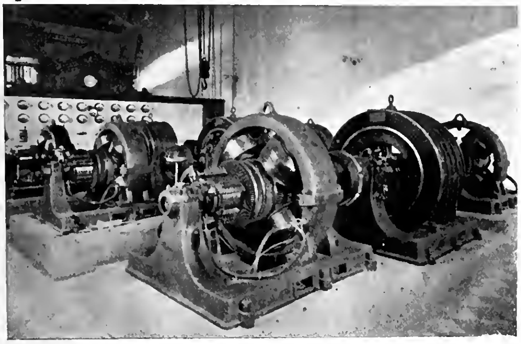

FIG. 5.—INTERIOR OF ST. CLAUDE SUB-STATION.

wires. The fourth main is to Oernon, and, after a course of 3.12 miles has a branch of 6.25 miles to Moiran, both circuits being of three 4-mm. wires.

The total length of the high-tension circuits is 65.4 miles. The wires are mostly carried on 33-ft. poles, of which there are 3,940.

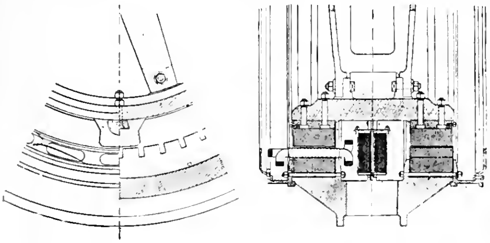

FIG. 6.—DETAILS OF 700-HP GENERATOR.

These poles are in straight stretches 98.4 ft. apart, while in curves 82 ft. is the usual distance. The greatest distance apart in any place is 246 ft. All poles are saturated either with copper sulphate or zinc chloride. They are fitted on top with pointed cast-iron caps or pro-

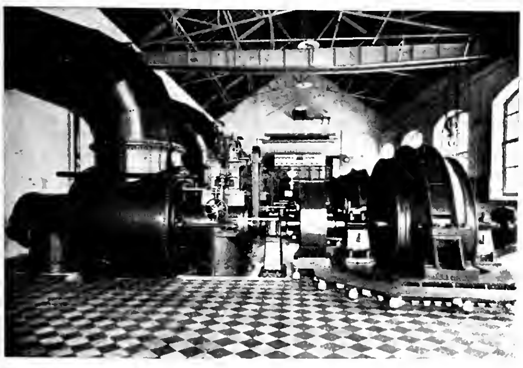

FIG. 7.—INTERIOR OF POWER HOUSE, SHOWING DRAFT TUBES.

tecting heads and a 4-mm. copper wire leading to the earth and ending in a coil, for lightning protection. All poles are wound with barbed wire for protection against boys and on curves iron loops are mounted on the poles in such a manner that if an insulator is broken the wire does not fall, but remains supported in the loop. Where the wires are carried over railroads, braced pairs of double poles are erected. Over streets there is underneath the span a steel wire netting. In towns the high-tension wires are insulated with cables, while elsewhere the wiring is bare.

There are 18 isolated transformer buildings of brick, each containing one transformer, except at St. Claude, where there is a sub-station in which there are four transformers of 70 kw each.

The electrical outfit for a transformer house consists of a three-pole switch for high-tension circuit, a three-pole switch for the low-tension circuit, fuses and lightning arresters for the high and low-tension circuits, and a transformer of the Oerlikon type.

The sub-station at St. Claude is of two stories, in the upper one being placed three motor-generator groups and the switchboard. There is also a 7-ton hand crane. Each transformer group is composed of three machines, a three-phase, high-tension motor, the shaft of which is coupled at each end by means of an insulated elastic coupling with a direct-current dynamo, as shown in the illustration.

The Oerlikon motor, of 150 hp makes 590 r.p.m. and its ten poles are fed at a pressure of 200 volts. The stator is provided with 150 slots, each containing one conductor of 14 parallel bare copper wires of 3.8 mm. diameter. The rotor has 180 slots with one conductor each, of 6 parallel bare wires 4 mm. in diameter each.

The Oerlikon direct-current dynamos develop 75 hp at 590 r.p.m.

FIG. 8.—REAR OF SWITCHBOARD IN POWER HOUSE.

and a voltage of 200. The armature has 117 slots 1/4 x 1 1/8 in., containing two conductors of three parallel 4-mm. bare wires each. The commutator consists of 117 copper segments.

The four coils of the magnet field are connected in series. Each has 2,450 windings of 1.8 x 2.2 wires. The efficiency of the transformer groups by actual test is from 85.5 per cent. to 86.8 per cent.

The different portions at the rear of the switchboard are accessible from an aisle along the middle. At the back are four transformers which feed the three-phase motors of the generator groups, as are also the high-tension switches, safety fuses and lightning arresters of the high-tension circuit. At the front are the switches of the secondary three-phase and the direct current, the first mentioned for general commercial consumption and the latter for municipal and private lighting at St. Claude.

Below each switch is the fuse for the circuits. The same room contains switches for the machines, carbon cut-outs, rheostats, etc. The apparatus room is separated from the machine room by a white marble switchboard upon which are mounted the usual measuring devices and switching levers.

The small manufacturers are supplied with 200-volt, three-phase motors of from 1/2 to 35 hp, there already being 58 such motors installed with a total capacity of 684 hp. The alternating-current service is from a 120-volt circuit, while the direct-current service is at 200 volts. There are 5,200 incandescent lamps of 58,000 total cp, of which 2,000 are on three-phase circuits in different towns, the 3,200 direct-current lamps being in use in St. Claude, the latter place alone having direct current.

Horse Power of Steam Engines.

By Irving A. Taylor.

It is often desirable to be able to figure the power of an engine from its dimensions and other apparent data. Usually this task is not as simple as it appears at first blush. One starts out with the theoretical mean effective pressure, and reduces it to practical conditions as best one can.

It is the object of what follows to give a handy and fairly simple method of arriving at an approximate result, correct in ordinary cases to within 5 or 10 per cent. It is not possible to give a general solution of much greater accuracy, on account of the variable character of the sources of loss.

Engine builders vary to some extent in their rating, but generally they rate rather high for practical conditions. In non-condensing engines, for example, the usual rating is made on a basis of atmospheric pressure in the exhaust—a condition seldom holding in practice, and allowance for wire-drawing in the valves is generally absent.

Two of the greatest difficulties in the way of obtaining accurate results in figuring power are, first, the variable and often large loss of pressure occurring in the steam and exhaust piping; and, second, the same loss occurring in the ports and valves of the engine itself. The writer sometime ago saw cards taken from large modern engines running on 28-in. condenser vacuum, which showed only 15-in. vacuum on the low-pressure exhaust line. Needless to say, such a loss reduces the power and efficiency to an extent difficult to figure, except on the cards themselves.

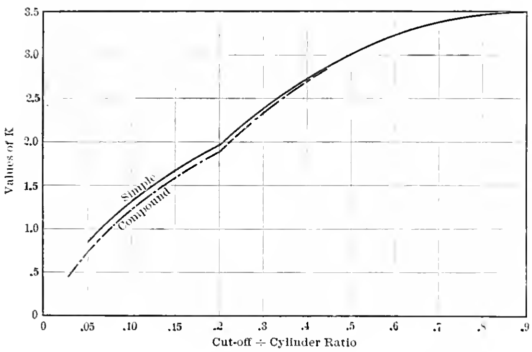
The following equations and the curves of the accompanying figure curves show the method of figuring the power:

$$H.P. = \frac{P \times diam.^2 \times stroke'' \times revs.}{1,000,000}$$

$$P = (steam\ gauge\ pressure + 15)\ K - (68\ or\ 20).$$

The constant, 68, is used for non-condensing, and 20 for condensing engines.

For single-acting engines the horse-power will be one-half that given by the equation. The diameter in the equation for horse-power is in inches, and in compound engines is the diameter of the low-pressure cylinder.



CALCULATING THE HORSE-POWER OF STEAM ENGINES.

The values of K may be found from the curve when the cut-off is known. The following cut-offs represent approximately the proper rating, the cut-off in the compounds being equal to the cut-off in the high-pressure cylinder divided by the ratio of low to high-pressure piston areas:

	Simple.	Compound.
Non-condensing	.25	.125
Condensing	.15	.075

The point of maximum cut-off in the high-pressure cylinder divided by the cylinder ratio determines the maximum output which the engine is capable of giving. In simple engines it is usually $\frac{5}{8}$ to $\frac{3}{4}$ stroke, and in compounds $\frac{3}{4}$ stroke, though occasionally $\frac{7}{8}$ stroke.

The equations are based on 24-in. vacuum for condensing engines, or 17 pounds absolute pressure in the case of atmospheric exhaust.

The following examples illustrate the method of application:

SIMPLE ENGINE.

22 in. diameter x 18 in. stroke, 220 revolutions, 80 pounds steam.

NON-CONDENSING.

Rated with cut-off at $\frac{1}{4}$ stroke.

$$P = [(80 + 15 = 95)\ 2.2 = 209] - 68 = 141.$$

$$H.P. = \frac{141 \times 22^2 \times 18 \times 220}{1,000,000} = 270\ H.P.$$

Maximum power with cut-off at $\frac{5}{8}$ stroke:

$$P = [(80 + 15 = 95)\ 3.27 = 310.5] - 68 = 242.5.$$

$$H.P. = \frac{242.5 \times 22^2 \times 18 \times 220}{1,000,000} = 465\ H.P.$$

CONDENSING.

Rated with cut-off at .15 stroke:

$$P = [(80 + 15 = 95)\ 1.7 = 161.5] - 20 = 141.5.$$

$$H.P. = \frac{141.5 \times 22^2 \times 18 \times 220}{1,000,000} = 271\ H.P.$$

Maximum power with cut-off at $\frac{5}{8}$ stroke:

$$P = [(80 + 15 = 95)\ 3.27 = 310.5] - 20 = 290.5.$$

$$H.P. = \frac{290.5 \times 22^2 \times 18 \times 220}{1,000,000} = 557\ H.P.$$

COMPOUND ENGINE.

18 in. and 32 in. diam. x 26 in. stroke, 116 revs., 125 pounds steam.

$$Cylinder\ ratio = \left(\frac{32}{18}\right)^2 = 3.16.$$

NON-CONDENSING.

Rated with cut-off at $\frac{1}{3}$ stroke in the high-pressure cylinder:

$$\tfrac{1}{3} \div 3.16 = .1056\ cut\text{-}off$$

referred to the low-pressure cylinder.

$$P = [(125 + 15 = 140)\ 1.24 = 173.5] - 68 = 105.5.$$

$$H.P. = \frac{105.5 \times 32^2 \times 26 \times 116}{1,000,000} = 325.7\ H.P.$$

Maximum power with cut-off at $\frac{3}{4}$ stroke:

$$\tfrac{3}{4} \div 3.16 = .237\ cut\text{-}off$$

referred to the low-pressure cylinder.

$$P = [(125 + 15 = 140)\ 2.06 = 288.4] - 68 = 220.4.$$

$$H.P. = \frac{220.4 \times 32^2 \times 26 \times 116}{1,000,000} = 680\ H.P.$$

CONDENSING.

Rated with cut-off at $\frac{1}{4}$ stroke:

$$\tfrac{1}{4} \div 3.16 = .0791\ cut\text{-}off$$

referred to the low-pressure cylinder.

$$P = [(125 + 15 = 140)\ 1.01 = 141.4] - 20 = 121.4.$$

$$H.P. = \frac{121.4 \times 32^2 \times 26 \times 116}{1,000,000} = 374.6\ H.P.$$

Maximum power with cut-off at $\frac{3}{4}$ stroke:

$$\tfrac{3}{4} \div 3.16 = .237\ cut\text{-}off$$

referred to the low-pressure cylinder.

$$P = [(125 + 15 = 140)\ 2.06 = 288.4] - 20 = 268.4.$$

$$H.P. = \frac{268.4 \times 32^2 \times 26 \times 116}{1,000,000} = 828.6\ H.P.$$

The examples given show that there is always a considerable margin of power in engines above their normal rating; so, if an engine builder overrates his machines somewhat, he is not likely to get into "deep water" on account of it.

The accompanying curves give the values of K in terms of the cut-off divided by cylinder ratio. Makers usually rate power with the figure 60 instead of 68 in the equation for P, and with K from 1 to 1.1 times that shown in the curves. Simple engines having very restricted port areas may have values of K, but .9 of that shown, while for compounds, under the same conditions, K is .75 to .9 of that shown. First-class engines, with sufficient port areas, will have values of K approximately as given in the curves, though the best Corliss valves or equivalent may give 5 to 10 per cent. greater, as may also abnormally large clearances in ordinary types.

The Elementary Principles of Transformer Design—I.

By Prof. Thomas Gray.

THE following paper is, in a somewhat expanded form, part of the notes on a course of lectures on transformers which have been used for sometime by the writer at Rose Polytechnic Institute. The treatment is brief, the object being to give, in moderate space, an outline of a method of treatment which may be followed with advantage in making an original design for a transformer. The forms of section and so forth used, in the development here given, were chosen with a view to simplicity of algebraic expression, no particular attention being given to details of manufacture or shop conditions. It will be found easy for any one who understands the conditions of manufacture and who has an elementary knowledge of mathematics to modify the formulæ to suit particular cases. It may be remarked, besides, that considerable departures from the theoretically best form does not usually mean great sacrifice of efficiency.

The methods commonly recommended for use in the design of transformers are, to a large extent, based on empirical rules, derived either from forms already in use and known to give fair efficiency of from a process of trial and selection. In the latter case a number of different forms are tried and those that give the best calculated efficiency selected as the best types. Such a method of proceeding is both wasteful of time and unsatisfactory. The prevailing idea seems to be that a purely theoretical method is either impossible or is, at least, excluded from consideration because of its difficulty. The reason given is the number and conflicting character of the variables involved.

It appears from the following discussion that the proper size and form of a transformer of any particular type can be accurately predetermined if sufficient data be available as to the magnetic properties of the iron and the working conditions. In order to obtain brevity of treatment a comparatively simple form and arrangement of the parts has been chosen in the examples here given, but the determination of the proper formulæ for any of the ordinary types and relative arrangements of the iron, coils and insulation can be readily made.

The problem which presents itself is to obtain the form which will give the requisite output of activity with the minimum input. In other words, which for a given capacity will dissipate the smallest amount of energy in a given time. One important condition has to be complied with, namely, that the energy dissipated shall not raise the temperature too high. This puts a limit on the diminution of the radiating surface. The form of cross-section of the interlinking rings must, of course, be such as can be satisfactorily and economically manufactured. Only one type of section is discussed, namely, the rectangular. It may appear that some advantage is obtained by rounding the corners of the links and of the sections, and the first of these is common practice. The second can only be done at the expense of some inconvenience in manufacture, but it must be remembered that the proper ratio of the relative dimensions may be considerably changed by such modifications of form. This is referred to and illustrated by a few examples further on.

TWO-LINK TRANSFORMERS.

Consider first the case of two closely fitting rectangular links, as shown in Fig. 1, in which one end of each link is assumed to be

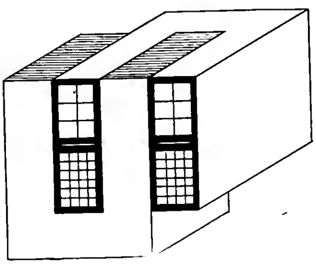


FIG. 1.—TWO LINKS.

cut off. In this case one of the links is of iron, while the other is made up of the primary and secondary coils and their insulation. Let the dimensions of the cross-section of the iron link be a_1 and b_1, and let l_1 be its mean length. Similarly let a, b and l be the corresponding dimensions of the coil link. Putting A_1 and A for the areas of cross-section of the iron and of the coils, the following equations hold:

$$ab = A \qquad (1)$$

$$a_1 b_1 = A_1 \qquad (2)$$

$$l = 2(a_1 + b_1 + 2a) \qquad (3)$$

$$l_1 = 2(a + b + 2a_1) \qquad (4)$$

$$lA = 2ab(a_1 + b_1 + 2a) = v \qquad (5)$$

$$l_1 A_1 = 2a_1 b_1 (a + b + 2a_1) = v_1 \qquad (6)$$

Equations (5) and (6) give the volumes of the links and it is evidently desirable to have as large a section and as small a volume as possible. It is clear that as far as the coil is concerned the least value of l for a given value of A and A_1 would be got if $a_1 = b_1$ and b were made very large, while the product ab remained constant. This condition would give a large value for l_1 and consequently for the volume of the iron. The question as to whether the iron link or the coil link should have the greater volume depends on a variety of circumstances, such as the relative cost of the two per unit volume, the relative energy economy of different proportions, the cost of energy, the relative time that the transformer is on the circuit, loaded and unloaded and so forth.

Consider first the case in which A, A_1 and v_1 are constant and let the problem be to determine the relative values of a, b, and a_1, b_1, so that l shall be minimum.

From equations (1) and (4) the value of a_1 is

$$a_1 = \frac{l_1}{2} - a - \frac{A}{a},$$

and from (2) and (5)

$$l = 2\left(a_1 + \frac{A}{a_1} + 2a\right)$$

Substituting for a the value of l becomes

$$l = 2\left\{\frac{l_1 a - 2(a^2 + A)}{4a} + \frac{4a A_1}{l_1 a - 2(a^2 + A)} + 2a\right\} \qquad (7)$$

Differentiating this equation, putting the result equal to zero and educing,

$$l_1 = 2\left\{a + b + 2\sqrt{A\frac{A - a^2}{A + 3a^2}}\right\} \qquad (8)$$

This equation, when compared with (4), shows that

$$a_1^2 = A_1 \frac{A - a^2}{A + 3a^2} = a_1 b_1 \frac{b - a}{b + 3a}$$

$$\therefore \quad \frac{a_1}{b_1} = \frac{b - a}{b + 3a} \qquad (9)$$

It follows, of course, that

$$\frac{a}{b} = \frac{b_1 - a_1}{b_1 + 3a_1} \qquad (10)$$

The relations here obtained for the ratio of the two dimensions of the iron section, if those of the coil section are known, and vice versa, are clearly independent of the magnitudes of the sections, and, therefore, hold for all cases of two closely interlinking rectangular rings. Equation (8) can, of course, be used for the determination of a, and hence by means of (7) the minimum value of l obtained. This is not in itself important, and the problem just given is a particular case of the following more general one:

The areas of the sections A and A_1 being assumed known, what should the ratios $b \div a$ and $b_1 \div a_1$ be so that $v + v_1$ shall be a minimum?

Here

$$v + v_1 = A\left(a_1 + \frac{A_1}{a_1} + 2a\right) + A_1\left(a + \frac{A}{a} + 2a_1\right)$$

and when A and A_1 are constant,

$$\frac{d}{da}(v+v_1)=\frac{da_1}{da}\left\{1-\frac{A_1}{a_1^2}+2\frac{A_1}{A}\right\}+\frac{A_1}{A}\cdot\frac{a^2-A}{a^2}+2,$$

which must be zero for the minimum value of $v+v_1$. This is satisfied when

$$1-\frac{A_1}{a_1^2}+2\frac{A_1}{A} \text{ and } \frac{A_1}{A}\cdot\frac{a^2-A}{a^2}+2$$

are both zero, and this also satisfies the condition imposed by the result stated in (9) and (10). The result is:

$$a^2=\frac{A A_1}{A_1+2A} \text{ and } b^2=A\,\frac{A_1+2A}{A_1} \qquad (11)$$

$$a_1^2=\frac{A A_1}{A+2A_1} \text{ and } b_1^2=A_1\,\frac{A+2A_1}{A} \qquad (12)$$

These equations apply to any case where the areas are of given size and serve under such circumstances to determine the shape. It is easy to show that equations (11) and (12) include (9) and (10).

Should it be considered more desirable to use a given ratio of volume instead of the ratio of sections it is easy to express the volume ratio in terms of the section ratio and hence of course the section ratio in terms of the volume ratio.

Let $v_1=n\,v$ and $A_1=x\,A$.

Then $n\,A\,(a+b+2a)=A_1\,(a+b+2a)$.

Substitute for a_1, b_1, etc., in terms of A_1 and A and

$$n\,A\left\{\sqrt{\frac{A A_1}{A+2A_1}}+\sqrt{A_1\frac{A+2A_1}{A}}+2\sqrt{\frac{A A_1}{A_1+2A}}\right\}$$
$$=A\left\{\sqrt{\frac{A A_1}{A_1+2A}}+\sqrt{A\frac{A_1+2A}{A_1}}+2\sqrt{\frac{A A_1}{A+2A_1}}\right\}$$

Hence,

$$n=\frac{(x+1)\sqrt{1+2x}+x\sqrt{x+2}}{(x+1)\sqrt{x+2}+\sqrt{1+2x}}$$

This is a cubic equation for the determination of x in terms of n, and hence it is more convenient to assume values of x and calculate the corresponding values of n, then either show relative values by means of a curve or tabulate the results. The graphic method is the more convenient and a set of curves showing the values of the quantities expressed by the above equations in terms of n, and, of course, indirectly in terms of x is given in Fig. 2. For convenience

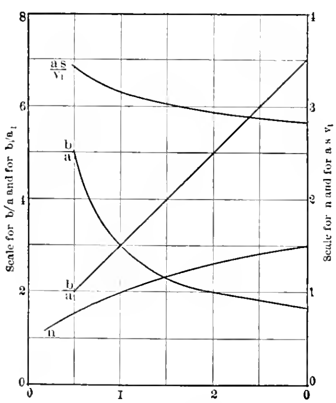

FIG. 2.—CURVES.

in the application of these equations to transformer design a curve showing the ratio of the total exposed area multiplied by the linear dimensions, a, to the volume of the iron link is included in this figure. The use of this curve is illustrated below.

So far as efficiency is concerned, without reference to relative cost of material, conditions of operation, etc., it is easy to see that the best results will be obtained when the heat dissipated in the coils is equal to that dissipated in the iron. Let the heat dissipated in the iron be H_1 and that in the coil $M\,C^2R$, where C is the current in the primary coil. Then the efficiency is

$$e=\frac{M_1E\,C-M\,C^2R-H_1}{M_1E\,C}$$

Hence,

$$\frac{d\,e}{d\,C}=\frac{M\,C^2R-H_1}{C^2}$$

which, when equated to zero, gives $M\,C^2R=H_1$.

Again the heats dissipated in the coils and in the iron are each proportional to the volume of these parts. Hence, if there be no

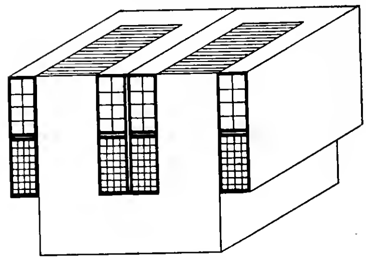

FIG. 3.—THREE LINKS.

preference as to which volume should be greatest the total volume may be taken as constant while v and v_1 are varied so as to give the least total heat dissipation. This gives the following equations:

$a\,v=a_1v_1=$ heats dissipated in coils and iron respectively,

$a\,v+a_1v_1=H=$ total heat dissipated,

$v+v_1=V$, a constant.

Hence, it follows that $a=a_1$ and $v=v_1$ for greatest efficiency. When this is the case the links become both equal and similar. It follows from equations (9) and (10) that

$$\frac{a_1}{b_1}=\frac{b-a}{b+3a}=\frac{a}{b}$$

hence,

$$b^2-2a\,b-3a^2=0,$$

or

$$b=3a=3a_1=b_1.$$

It appears, therefore, that for a given volume of iron and copper, supposed equal to each other so as to obtain the highest electrical efficiency, the ratio of length to breadth of cross-section should be 3 in the two-link type when rectangular links are used.

The total exposed areas of two links of the kind here assumed and fitting closely to each other is

$$(2a_1+b_1)\,(4a_1+2a+b)+(2a+b)\,(4a+2a_1+b_1)$$
$$+\,4\,(a_1b_1+a\,b)$$

When $b=3a=b_1=3a_1$, this becomes $114a^2$. The volumes of the same two links under the same condition is found by substitution in equations (5) and (6) to be $72a^3$. Hence, if S be the exposed surface,

$$\frac{S}{v}=\frac{114a^2}{72a^3}=\frac{57}{36a}.$$

When full load is taken as that which gives the greatest efficiency experience shows that this ratio should be from 60 to 70 times the number of watts dissipated in heat in the iron links. This condition, therefore, determines the intensity of the magnetic induction in the iron and consequently the best total activity for a transformer of this two-link type and of any given linear dimension, a. Similar data can be readily obtained for any relative value of cross-sections or volumes of the links. As stated above, this data is given in the form of a curve in Fig. 2.

THREE-LINK TRANSFORMERS.

There are two distinct types of three-link class, namely, "core" and "shell" transformers. In the first there is a single iron link and two coil links, while in the second there is a single coil link and two iron links. The general form is indicated in Fig. 3, one end of each link being assumed cut off to show the section.

Core Transformers.—Consider first the "core" type. Let a and b be the dimensions of the rectangular opening in the iron link. This will, evidently, for a close fitting arrangement, be the same as the sum of the coil sections. The total coil section will thus be the product $a\,b$. Let l be the mean length of the turns of each coil, which will be assumed the same as if the wires were uniformly distributed across the section. Also let a_1, b_1 and l_1 be the corresponding dimensions for the iron link. Then

$$a\,b = A \text{ and } a_1 b_1 = A_1, \tag{13}$$

$$l = 2\,(a_1 + b_1 + a) = 2\left(a_1 + \frac{A}{a_1} + a\right) \tag{14}$$

$$l_1 = 2\,(a + b + 2a_1) = 2\left(a + \frac{A}{a} + 2a_1\right) \tag{15}$$

where A represents the sum of the sections of the coils and A_1 the section of iron. Following the same order of discussion as before, assume A, A_1 and l_1 to be constant and find the proper ratios, $\frac{b}{a}$ and $\frac{b_1}{a_1}$, so that l shall be a minimum. In this case

$$4a_1 = \frac{a\,(l_1 - 2a) - 2A}{a}$$

$$\therefore l = 2\left\{\frac{a\,(l_1 - 2a) - 2A}{4a} + A_1\frac{4a}{a\,(l_1 - 2a) - 2A} + a\right\}$$

Differentiating, with respect to a and equating to zero, it is found that

$$l_1 = 2\,\frac{a^2 + A}{a} + 4\sqrt{A_1\frac{A - a^2}{A + a^2}}$$

Hence, by comparison with (15),

$$a_1^2 = A_1\frac{A - a^2}{A + a^2}$$

and, therefore,

$$\frac{a_1}{b_1} = \frac{b - a}{b + a} \tag{16}$$

and

$$\frac{a}{b} = \frac{b_1 - a_1}{b_1 + a_1}. \tag{17}$$

These equations only differ from (9) and (10) in having a instead of $3a$ in the denominators. In the two-link case the links could be made exactly similar and remain close fitting, so that equality of volumes corresponded to equality of sections and corresponding linear dimensions. In this case the links cannot be exactly similar and remain close fitting. Equality of sections does not, therefore, imply equality of volumes.

When the sections of the coils and of the iron are given and the problem is to find the relative dimensions of the sections which give the least total volume for the three links the equations are

$$A\,(a_1 + b_1 + a) + A_1\,(a + b + 2a_1) = v + v_1;$$

and, therefore,

$$\frac{d\,a_1}{d\,a}\left\{A - \frac{A_1 A}{a_1^2} + 2A_1\right\} + A + A_1 - \frac{A\,A_1}{a^2} = 0;$$

$$\therefore \quad a^2\,(A + A_1) - A\,A_1 = 0, \text{ or } a^2 = \frac{A\,A_1}{A + A_1}.$$

Hence, also,

$$a_1^2\,(A + 2A_1) - A\,A_1 = 0, \text{ or } a_1^2 = \frac{A\,A_1}{A + 2A_1};$$

$$\therefore \quad a^2 = \frac{A\,A_1}{A + A_1} \text{ and } b^2 = \frac{A\,(A + A_1)}{A_1}, \tag{18}$$

$$a_1^2 = \frac{A\,A_1}{A + 2A_1} \text{ and } b_1^2 = \frac{A_1\,(A + 2A_1)}{A}. \tag{19}$$

It may be observed in passing that equations (19) are identical with equations (12), and hence that the relative dimensions of the single link are the same in the two-link and three-link types when the sections have the same relative values.

When the volumes are to have a definite relative value, let $n\,v = v_1$ and the corresponding relative value of the areas be $A_1 = x\,A$. Then

$$nA\,(a_1 + b_1 + a) = A_1\,(a + b + 2a_1).$$

Substituting from (18) and (19) and reducing, the value of n in terms of x is found to be

$$n = \frac{(1 + 2x)^{\frac{3}{2}} + 2x\,(1 + 2x)^{\frac{1}{2}}}{2\,(1 + x)^{\frac{3}{2}} + (1 + x)^{\frac{1}{2}}} \tag{20}$$

A set of curves showing the values of the ratios $\frac{b}{a}$, $\frac{b_1}{a_1}$, x and the ratio of the exposed surface multiplied by a to the volume of the iron, in terms of the ratio of the volumes n is given in Fig. 4.

Shell Transformers.—In the shell type of transformers the formulæ just developed for the three-link core transformer apply if the symbols for section, linear dimensions and so forth be interchanged.

The single link becomes in this case the coils and the double link the iron. The iron may in this case be continuous through the two links, as in several well-known forms, or two separate iron links may be built up. The curves given in Fig. 4 apply in this case, when

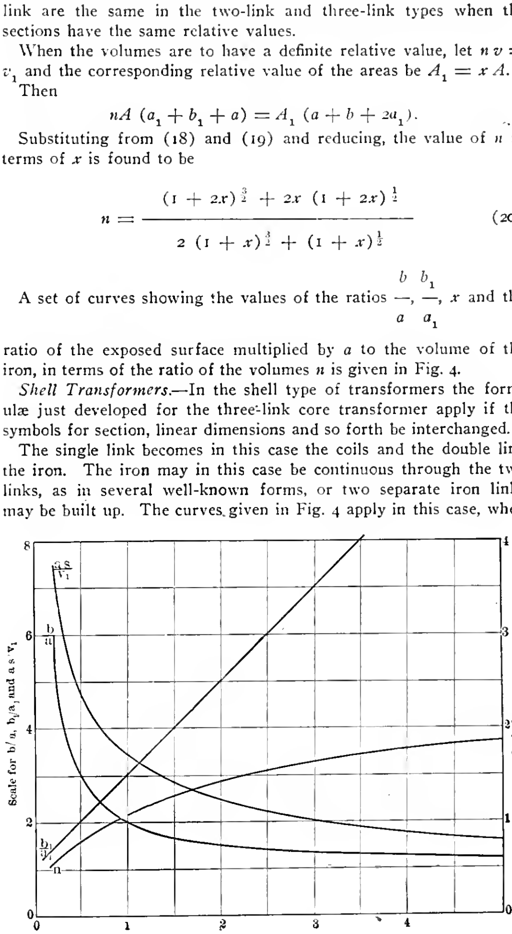

FIG. 4.—CURVES.

the proper interchange is made, with the exception of that for Sa/v_1, in which v_1 should now be the volume of the double link. It is easy, as is done below, to so modify the formulæ for practical applications that the curve given can be used and hence no separate curve has been added.

Short Rations.

The Commercial Pacific cable staff, at Midway Island, in the Pacific Ocean, ran short of food recently owing to the inability of the United States transport *Buford* to land two tons of stores on account of the rough sea. The stores were carried to Manila and were sent to Midway Island by another boat.

The Prevention of Crosses Between Signalling and High Voltage Circuits.

By Howard S. Knowlton.

THE applications of modern science to large industrial enterprises are always more or less complex. Fundamental principles may be simple enough, but their commercial use on a large scale is quite another story. This often applies to small pieces of apparatus as well as to large systems. The familiar electric push button, elementary as its function is, furnishes a case in point. Designed simply to bring two pieces of metal together, thereby closing the connected circuit, it consists of no less than fifteen parts: base, knob, cap, two springs, four washers and six screws. Similar multiplication of details may be seen in the telephone receiver, and found to occur in the parallel development and mutual relations of specialized branches in any given field of engineering.

During the past fifteen years the transmission of power at high voltages has advanced with tremendous strides. Only a few years ago the Niagara Falls-Buffalo line, operating at 11,000 volts and carrying power some twenty-six miles, was considered one of the electrical wonders of the world. To-day we talk of power sent 200 miles at 60,000 volts with little concern—unless we operate such a line, or try to telephone safely over the same right of way. This does not mean that the Niagara transmission and its plant have suffered in interest at the hands of electrical engineers, for it is one of the great industrial triumphs of the nineteenth century, and in its adoption of double the original voltage of transmission, its remarkable switchboard control and its growth to meet the needs of heavy power consumers it is as worthy an object of study as any installation that could be named.

Signalling circuits of all kinds have been multiplying meanwhile throughout the country, but the great bulk of telephone and telegraph wires which tie its communities together was planned, located and constructed prior to the advent of the transmission lines. The increasing number of circuits carrying high-potential currents has greatly complicated the signalling question, and in many instances it has introduced dangerous elements into the safe and reliable transmission of intelligence. It is important to consider some of these dangers and the methods of preventing them.

It is unnecessary here to specify in detail what may happen if a high-voltage line and a signalling circuit come in contact with one another. It is not pleasant to consider the possibilities of fatal shock, personal injury and destruction of apparatus and property through fires which such a calamity entails. It is easy to picture the consequences of letting a 25,000-volt current loose upon a telephone line designed to withstand but a few hundred volts at the outside. It is hard to find a case where an ounce of prevention is more evidently worth a hundred tons of cure.

Standard protective devices like fuses, circuit-breakers and lightning arresters have generally proved adequate in the event of crosses between telegraph, telephone, fire alarm circuits and wires carrying foreign currents at potentials up to about 2,500 volts. Beyond this limit of potential protection is problematical, and the need of extraordinary precautions becomes of vital importance. It is naturally impossible to lay down hard and fast rules applying to all cases met in practice, but there is one general requirement which must be perpetually kept in mind—*under no circumstances whatever should signalling and high-potential wires come in contact.*

Whenever new lines are laid out the hazard in question should be kept in mind so that the near approaches of signalling and power wires may be made as infrequent as local conditions permit. On existing lines wherever there is a liability of contact, the route should be changed by mutual agreement between the parties in interest whenever possible. In open country this should not be difficult to accomplish, if the right of way is flexible.

Mountainous regions frequently interpose almost insurmountable obstacles to the proper separation of high-potential and signalling circuits. Great chasms, narrow trails of appalling steepness, impassable gorges and rocky precipices demand types of line construction utterly different from that required in level or rolling country. Special forms of iron braces adapted to each individual case, the placing of signalling circuits underground at crossings with power lines, and the use of most substantial poles, double cross arms and guys are imperative if safe, continuous service is to be maintained. Avalanches of snow and rocks usually render the best of precautions valueless if the power and signalling lines are located in the direct path of the slide as it plunges down the mountains. About the only known preventive of such lines coming together in cases like this is to spend prohibitive sums of money in crossing the mountain ranges by entirely different routes, if the locations cannot be separated otherwise. It is a serious problem when one is asked to carry a number of telephone circuits and a 60,000-volt transmission line safely through a cañon perhaps a hundred feet wide, with almost perpendicular walls of rock 2,000 ft. high, towering above a turbulent river at the bottom. Something more than "paper engineering" is demanded in the solution. Nothing short of a careful investigation on the ground is likely to be of much use.

In open country the simplest way to prevent contacts of power and signalling circuits is, of course, to run the two lines sufficiently far apart so that if either one falls down it will in all cases clear the other. Such lines should not approach one another nearer than the distance equal to the height of the taller pole line. Telephone and telegraph wires should be kept off the cross arms or poles of the power line, excepting the private signalling circuits of the power company. Even these open up the possibility of serious shock, a noisy private telephone line and the burning out of buildings if the construction is not maintained in excellent condition, and it is an open question if such circuits are not better off on a pole line of their own. Whenever high-tension and signalling lines approach

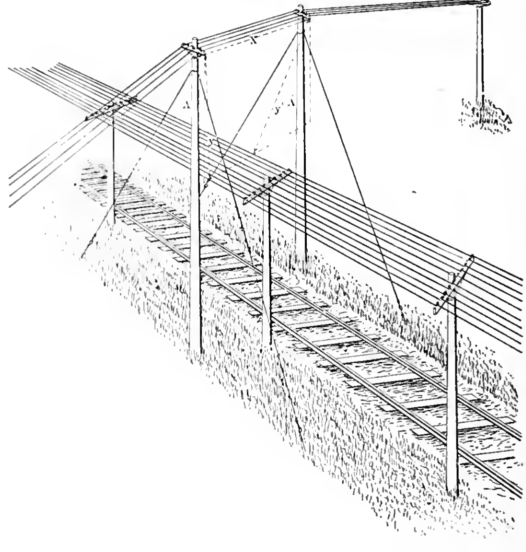

FIG. 1.—TELEPHONE WIRES UNDER HIGH-POTENTIAL WIRES.

one another nearer than the height of the taller poles, the damage may be reduced by bracing or guying the poles of the taller line with extra care. When it is absolutely necessary to carry signalling lines on the same poles with power circuits, extra precautions should be taken to reduce the liability of a break-down to a minimum, such as the use of wires of ample mechanical strength, widely spaced cross arms, short spans, double or extra heavy cross arms, extra heavy pins, insulators and poles carefully supported. The high-potential wires should be at least three feet above the telephone or telegraph line.

At times it becomes necessary for high-potential and signalling circuits to pass over or under one another en route. Extraordinary precautions are necessary to prevent crosses in such cases. The poles supporting the cross over span should be specially selected, braced and guyed, and the wires of the crossover span should be strung with more than the usual sag in order to render breakage less liable when the wires are loaded with sleet. When the high-tension wires are considerably fewer in number and greater in tensile strength than the telephone or telegraph wires, it is generally advisable to put the high-potential line overhead in making the crossing. Whenever it is feasible, end insulator guards should be placed on the cross arms of the upper line. To prevent the case of a wire breaking on either side of the crossover span, overhauling and sagging into contact with the line below, the wires at each end of the crossover span should be dead-ended to double-grooved or standard transposition insulators, and the line completed by loops fastened to the main wires. The danger of contact should still be further lessened by constructing a specially proportioned span or by guard wires.

Fig. 1 illustrates such a crossing as would be reasonably safe under most conditions of practice in open country. Here a two-phase, four-wire, high-potential circuit passes over a telephone lead: The height and length of the crossover span is made such that the distance, *Y*, between the nearest, and in this case, the only, cross arms of the upper line and any wire of the lower line is greater than the length of the crossover span, *X*. Thus, a wire breaking near one of the upper pins would not be long enough for its free end to reach any wire of the telephone line. In building this crossing the construction would be made still safer by the use of double cross arms and double-grooved insulators on the power line, with the addition of a standard ten-pin arm to each power pole in the cross-over span. These ten-pin arms should be bolted or lag-screwed into the power poles parallel to the telephone line and at about the same height above the ground, so that if a power wire should break on the outside of the crossover span, it would be difficult or impossible for it to curl up underneath the telephone line in a path perpendicular to it and thereby cause a cross. When telephone or telegraph poles are guyed near high-tension lines, care should be taken to include one or two powerful strain insulators in the guy wire, in case it is necessary to run the guy wire underneath the bare transmission line, or within range of its fall. Even if the guy is grounded the soil may be dry and a cross on the transmission circuit cause a bad burn-out on the telephone line, especially in the case of an underground construction where twisted pairs run down the pole near or adjoining the guy wire. In such cases safety may be attained by the use of a wooden strut or brace in place of the conventional galvanized-iron guy wire.

Fig. 2 is a sketch of a crossing where the telephone line runs overhead. In its essential features of protection it is similar to Fig. 1.

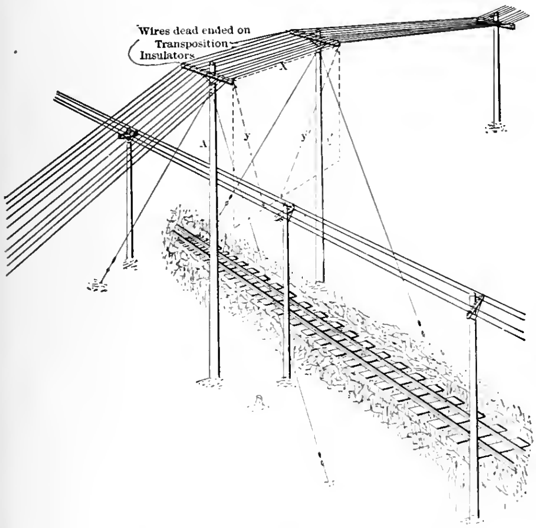

FIG. 2.—TELEPHONE WIRES CROSSING HIGH-POTENTIAL WIRES.

Here also added safety would be attained by the use of double cross arms, transposition insulators and extra cross arms on the telephone pole sides.

Another method of protection consists in the erection of a joint pole at the crossing point, the high-potential wires being supported on this pole at a distance of at least three feet above the telephone or telegraph wires. Mechanical guards or supports should then be provided, so that in case an upper wire breaks, it will be impossible for it to come in contact with any of the lower wires. Such liability to contact may be prevented by the use of suspension wires, similar to those employed for suspending aerial telephone cables, which will prevent the high-pressure wires from falling in case they break. These suspension wires should be supported on high-potential insulators; they should have ample mechanical strength and ought to be carried over the high-potential line for one span on each side of the joint pole; or where suspension wires are not desired guard wires may be carried above and below the lower wires for one span on each side of the joint pole, and so spread that a falling high-pressure wire would be held out of contact with the lower wires. Such guard wires ought to be either supported on high-potential insulators or else well grounded. When grounded they should be large enough in size to positively carry to ground any current which any of the high-pressure wires may deliver, and the construction should be such that the guard wires will not be destroyed by any arcing at the point of contact likely to occur under the conditions existing.

Fig. 3 shows still another method of making a crossing. Here the high-voltage line is above the telephone circuit, and a screen

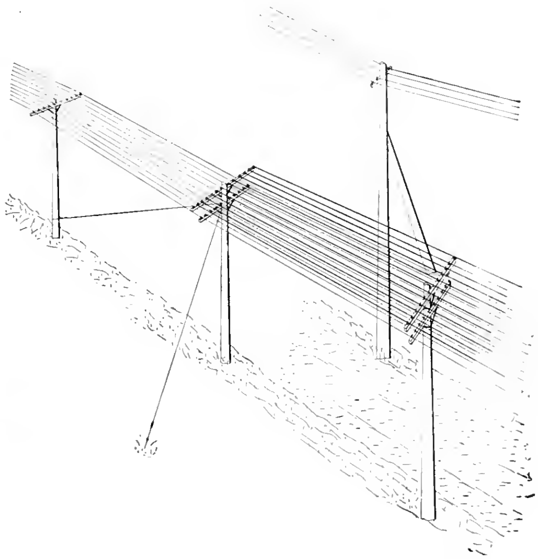

FIG. 3.—SCREEN FOR PROTECTING TELEPHONE AND OTHER WIRES.

of wires is interposed between the two lines at the crossover. This screen should always be supported on high-tension insulators or else grounded, and should be so constructed and mechanically strong enough to prevent the upper wires from coming into contact with the lower ones. The same conditions as to carrying capacity should be laid down as were previously indicated.

A type of crossing which has recently come into use in the Rocky Mountain regions is much in favor where the telephone lines are few in number, and form parts of local circuits. This is the "underground crossing" previously mentioned, and it is made by dead-ending the bare telephone wires on the usual bracket insulators; connecting these with one or more twisted insulated pairs of wires which run down the pole or tree into the ground. These twisted pairs then cross the aerial transmission line by a small underground trench three to five inches deep, reappearing and run up a pole or tree on the other side of the power line, connecting at the bracketed insulators with the metallic overhead telephone line again. In wooded country or on high, steep trails where the cost of labor and material is large, this scheme offers an attractive solution to the problem of protection. Care should be taken to run the twisted pairs on porcelain insulators in passing down or up the poles; in setting the poles far enough from the transmission line to avoid all chance of contact in case either line goes down, and lastly the twisted pairs in earth should be protected against dampness and mechanical injury by running them through a vitrified conduit or moisture-proof pipe.

Where both high-tension and telephone wires are carried underground, the cables of the high-potential lines should never occupy the same manholes or handholes, or the ducts of the same underground conduit as do the cables of the signalling system.

After the crossings in any territory have been made safe, it is advisable that they be kept so. To this end and also in order that any new or proposed crossings may be forestalled or made safe at the outset, a card catalogue record of every high-potential crossing in a company's system is an advantage. In order that all the information available in the territory under consideration may be gathered and properly filed, the signalling company should prepare printed blanks containing the following questions to be answered by its representatives in the field:

EXISTING CROSSINGS.

1. Location of crossing.
2. Name and address of company owning and operating high-potential lines.
3. Type of crossing—aerial or underground.
4. Which line is uppermost, the signalling or power wire?
5. Voltage of high-potential line.
6. Is the high-potential line direct current, single, two or three-phase?
7. For what purpose is the high-potential line used?
8. Do the crossing lines run on private rights of way?
9. When was the crossing built?
10. Which line was installed first, the signalling or power line?
11. Has the crossing ever proved defective? If so, in what way?
12. Has either the power or signalling line ever fallen to the ground in the vicinity of this crossing?
13. What precautions are taken to prevent accidental contact of signalling and high-tension circuits?
14. At what points in your territory do high-potential and signalling circuits run dangerously close to one another?
15. What precautions are taken to prevent accidental contacts at such points?
16. What changes from previous construction have been made at the crossing to promote safety?
17. State any suggestions as to the elimination of this particular crossing.
18. Note any comments which occur as not covered in the foregoing.

PROPOSED CROSSINGS.

1. Name and address of company or individual operating or proposing to operate the high-potential line.
2. Voltage of high-potential line.
3. Proposed or existing route of high-potential line.
4. Proposed or probable location of crossings with signalling circuits.
5. Has the high-potential right of way been secured?
6. In what cases, if any, will an established high-potential line be crossed by signalling circuits?
7. In what cases, if any, will an established signalling line be crossed by high-potential wires?
8. What crossings can be avoided?
9. State any suggestions as to the method of accomplishing this.
10. What plans, if any, are taking shape as to the method of making each crossing?
11. Does the proposed route of the high-potential line bring the signalling and power circuits into dangerous parallel runs?
12. When will construction begin on any proposed high-voltage line or crossing mentioned above?
13. For what purpose is the high-potential line to be used?
14. Is the high-potential line direct-current, single, two or three-phase?
15. State the number of signalling and high-voltage wires which are likely to cross at each crossing.
16. Specify briefly the route of signalling circuits which may be affected by crossings with high-potential lines.
17. Note any comments which occur as not covered in the foregoing.

It will be seen that certain detailed engineering information is lacking in the required answers to the questions enumerated. If the general data asked for is supplied, it is an easy matter to secure the engineering data, in case the difficulties of any situation demand it. The satisfactory solution of the whole high-tension crossing proposition depends upon the harmonious action of both signalling and power companies, and in so far as the various parties in interest agree just so far will signalling science be advanced, the transmission of power honored and the public protected.

A New Push-Button Voltmeter Switch.

By CHARLES L. FITCH.

THAT the portable voltmeter for switchboard work is a nuisance will, we believe, be admitted by all. At least it has always seemed so to the writer, as he has picked it up with its attendant plug and cord, and tramped back and forth, when cutting in a new generator on a direct-current switchboard.

The switchboard with its equipment has been so much improved that it would hardly be recognized by its original prototype; but the plug and cord still remain with us, or at best are only replaced by the multi-point voltmeter switch, which is just about as bad, so far as the tramping goes.

It has always seemed as though the voltmeter should form an in-

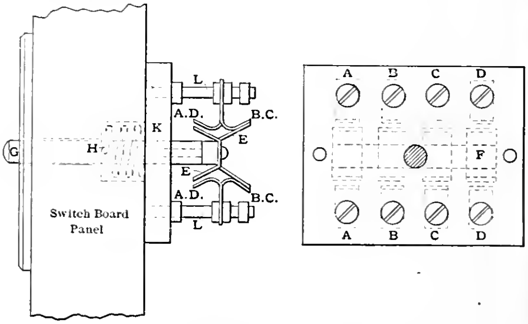

FIG. 1.—SECTION ELEVATION AND BASE PLATE.

tegral part of the switchboard, and all of its connections be of a permanent character like those of the other instruments; that it should be hung out upon brackets, so as to be visible from any point down the line, and normally register bus-bar voltage; and that each generator panel should be provided with a spring-actuated fly-back switch, by which the voltmeter is made to read across the terminals of that particular machine when the switch is operated, automatically returning to its bus-bar reading as soon as the switch is released. This would do away with all of the tramping, and is just what is accomplished through the little device illustrated herewith.

The switch itself, which is the essential feature, is of the push-button type, and has its moving parts all behind the board. It is

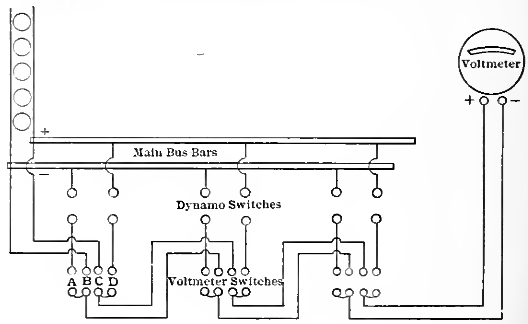

FIG. 2.—DIAGRAM OF CONNECTIONS.

essentially a double-pole, double-throw switch, but is made with eight contact points, as shown, for mechanical reasons, and because it is desirable to break contact at more than one point at once, to avoid the possibility of arcing.

The switch, as here constructed, has four pairs of contacts, *A*, *B*, *C* and *D*, two of which, *A* and *D*, open toward the front, and the other two toward the back. Each pair of contacts is arranged to be closed by one of four V-shaped plugs, *E*, which are carried on a cross-bar, *F*, operated from the front of the board by the push-button, *G*. A spiral spring, *H*, serves to hold the switch in its forward position with the contacts *B* and *C* closed, until the button is pressed, when *B* and *C* are opened and *A* and *D* are closed. When the button is released, the switch immediately returns to its original position.

The push-button rod, cross-bar and base plate, *K*, are of hard rubber, while the contacts are of red bronze. The steel rods, *L L*, which support the contacts, are threaded throughout their entire length, and are screwed through the base plate. They are provided with jam nuts, by moving the position of which the contacts may be accurately adjusted.

As may be seen from the drawings, the switch is very simple to make, its range of motion is quite small and there is nothing to get out of order.

In the diagram of connections shown, we indicate three of these voltmeter switches, as if mounted on three several generator panels of a direct-current switchboard. Above each voltmeter switch is shown the main dynamo switch of that panel, to the machine side of which the voltmeter switch is connected. The remainder of the diagram speaks for itself.

A set of these switches has been for a year past in daily operation on the switchboard of the generating plant of the Grand Union Tea Company, at Front, Pearl and Water Streets, Brooklyn, N. Y. This plant has a capacity of 1,000 hp and was designed by the writer. Its switchboard has five generator panels and one storage battery panel, all of which are provided with "push buttons." An inspection of them there will show how perfectly they work and how really convenient they are.

Recent Electrochemical Developments.

ELECTROMETALLURGY OF GOLD.

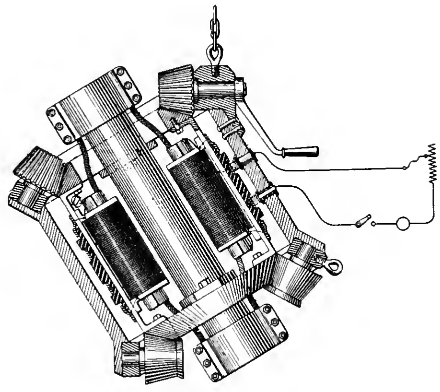
A patent was granted on April 5 to Mr. Charles Butters, who has been one of the most active workers in the introduction of the Siemens & Halske process for electrolytic precipitation of gold from cyanide solutions in South Africa, and who has modified this process in recent years in various plants in this country and in Mexico. In the original Siemens & Halske process the gold was plated upon the cathode and the anodes were of iron. The iron was gradually attacked, with the formation of prussian blue, and for this reason the iron anodes were covered by canvas or the like. Andreoli substituted lead peroxide for the iron anodes, with the result that the anode became practically undistructible. This enabled the use of a higher current density, but the gold is then no longer plated upon the cathode, but is deposited in a loose powdered or slimy form and may be easily wiped up from the surface, so that it is comparatively easy to collect the gold from the cathode. However, with the former cathode used, a difficulty was then experienced, for an iron cathode rusts and produces a rough surface, while aluminum cathodes become brittle and fall to pieces. Mr. Butters has found that a cathode of tin or of tinned iron is most suitable. He places the cathodes and anodes opposite to each other and passes the solution between the electrodes in an upward or downward direction, using a current density of 0.5 amp. per sq. ft. of cathode. The gold deposits in a loose slime form on the tin surface and may then be easily removed. Some very interesting details concerning this development on an industrial scale were recently given in a paper by E. M. Hamilton (*Electrochemical Industry*, April), who gives an account of the practical working of this modified Siemens & Halske process in various plants in this country and in Mexico.

Prof. S. B. Christy, of Berkeley, Cal., who has been quite active in the past in the development of the theory of the cyanide process, points out in a patent granted on April 5, that in the solution of potassium aurocyanide the cation is potassium, while the anion is complex and represented by the formula $AuCy_2$. This has been known since Hittorf, but the importance of this fact for practice has not been sufficiently appreciated. As a consequence of this fact, any current which passes through the solution deposits primarily potassium upon the cathode, and the deposition of gold is a secondary action. The current tends to bring the gold over to the anode. On the other hand, in order to get a gold deposition on the cathode it is of the greatest importance to have the solution rich in gold near the cathode, and the importance of good circulation is, therefore, evident. The author sends the current from a storage tank through the electrolytic cell and back again. In the cell he employs perforated anodes and cathodes alternately arranged. The solution is forced through the holes in the plates. The inventor claims that the speed of the deposition is greatly increased and that nearly the whole gold contained in the solution is taken out of it.

A patent granted to Mr. E. Fahrig, of Philadelphia, on April 5, relates to arrangements for winning the precious metals from low-grade ores and tailings by electrolysis. The finely-ground ores or tailings are mixed with water and a suitable electrolyte so as to form a pulp, which is then passed by gravity between a series of pairs of inclined anode and cathode plates arranged in tower fashion one below the other. The cathode plates are removable so that the deposited metals may be scraped off. The partially extracted pulp is then passed through a riffle trough into a leaching tank. Finally, the partially extracted pulp is subjected to filtration or decantation and the liquor is heated and subjected to electrolysis.

ELECTRIC FURNACE INVENTION.

A patent was granted on April 12 to Mr. Henry Noel Potter, of New York City, who has for some time been engaged in developing a convenient tube furnace. He uses a carbon tube lined and coated externally with fused magnesia which, under such conditions, does not shrink under the action of heat. The tube is also well jacketed by some good heat-resisting material, such as calcium oxide. The present patent relates to mechanical details of the arrangement for revolving the furnace and for supplying the current to the furnace. It is shown diagrammatically in Fig. 1. The furnace is provided with one or more transformers, the secondary of which feeds metallic



POTTER ELECTRIC FURNACE.

split rings forming the terminal connections of the furnace. The method of revolving the furnace is clearly shown in the illustration, and it will be seen that the material to be heated is passed in from the upper end and the rotation of the furnace causes the charge to feed regularly the lower end.

A patent granted on April 12 to Dr. G. Erlwein, of Berlin, Germany, relates to the manufacture of calcium cyanide from mixtures containing either calcium oxide and charcoal or calcium carbonate and charcoal, in the electric furnace, while nitrogen is conducted either over or through the mixture. It is stated that it is not necessary to employ theoretically correct proportions of the mixture, and that one may add to good advantage more charcoal or organic substances containing carbon, such as sawdust, pitch, tar or the like.

PRODUCING CHEMICAL COMPOUNDS FROM CALCIUM CARBIDE.

The chemical activity of certain metallic carbides is well known. A patent granted to Mr. J. J. Griffin, of Washington, D. C., relates to an interesting method of utilizing the chemical activity of calcium carbide for the production of various chemical compounds. He employs the calcium carbide as the material for the electrodes in an electrolytic cell. This is possible because, according to the inventor, calcium carbide conduits electricity like a metal. As an example of what happens in such a process, the electrolysis of an aqueous solution of sulphuric acid with calcium carbide electrodes in a diaphragm cell may be given.

The water of the solution reacts on both electrodes to give acetylene. At the cathode two atoms of hydrogen react on one molecule of acetylene to give ethylene, and four atoms of hydrogen react on one molecule of acetylene to give ethame. The ethylene so produced further reacts on the sulphuric acid in solution to give ethyl sulphuric acid. At the anode two atoms of oxygen react on one molecule of acetylene to give glyoxal, and four atoms of oxygen react on one molecule of acetylene to give oxalic acid. The inventor mentions quite a number of compounds which can be produced in this way, but does not give distinct directions how to obtain a certain desired pure compound in each case.

ELECTROLYTIC BLEACHING.

A patent granted on April 5 to Mr. A. A. Vogelsang, of Dresden, Germany, relates to apparatus for the bleaching of cotton yarn and other textile materials in large quantities, say a ton and upwards. The material is first treated with a solution of caustic soda, then with one of bleaching liquor, and finally with a weak solution of sulphuric acid. The apparatus comprises tanks for the preparation and reception of these solutions, an electrolyzer, vats for the bleaching operation and accessories. A special feature is the construction and preparation of the bleaching vat.

BATTERY INVENTION.

A patent granted on April 12 to Mr. G. W. Frost relates to mechanical details of construction of a storage battery grid. The grid comprises a rectangular frame, a series of retaining strips extending between the sides of the frame at each face of the grid, the strips of the two series being relatively staggered; and a horizontal web extending from each strip substantially through the grid.

Mr. C. B. Schoenmehl patents details of construction of primary cells with a depolarizer like copper oxide. In order to insure a uniform and thorough consumption of the depolarizer, he puts it into a receptacle whose breadth is greatest at the top.

Mr. E. Whitman patents a battery cell comprising a cylindrical member of carbon, surrounded by a coating of glass. The glass permeates the pores of the carbon in a similar way as when paraffin is used.

Messrs. A. F. Swan and A. W. Rose patent details of construction of a dry cell intended to get a large number of cells in as small a space as possible, and to render the switching operations easy.

New Telephone Patents.

THE TELEPHONE REPEATER.

Again the telephone repeater has been brought forward by the issuance of two patents to J. Trowbridge, of Cambridge, Mass., which describe respectively new repeating methods and means. For our purposes it would seem best to consider these patents together. The repeating apparatus is shown in Fig. 1 and consists of a granular

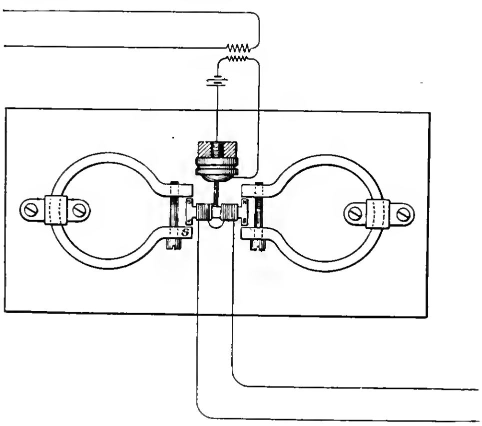


FIG. 1.—TROWBRIDGE TELEPHONE.

carbon transmitter button, secured to the middle of a diaphragm (not shown) in the usual manner and a motive apparatus, controlled by the received voice current, and actuating the diaphragm in response thereto. At *M M* are two permanent magnets, between the respective poles of which project the ends of a soft-iron armature piece. This latter carries at each end a coil, these being so connected together as to assist each other in the magnetization of the armature. As will be seen, the receiving line, *L*, is connected to the armature coils, while the transmitter button by means of a battery and induction coil, introduces repeated currents upon the line, *R*. The inventor finds that the receiving part of his instrument, in which the magnetic pull is balanced by the mechanical rigidity of the diaphragm, is very sensitive to minute received currents, the degree of sensitiveness being controllable by adjustment of the pole span of the permanent magnets. The use of a diaphragm as a support for the moving systems seems to be of advantage as a tell-tale for the inspector in charge of such instruments, in that it audibly repeats received currents, if the instrument be operating satisfactorily.

SELECTIVE SIGNALLING.

Selective signalling continues to be the subject of many patents, there being at hand for consideration three newly patented systems. The first of these to which attention will be given is the invention of B. Stryker, of Washington, D. C. This is a modification of the selective signalling system now standard with the Bell companies, the primary object being to overcome certain deleterious effects of earth potentials. In the system as previously adopted, a relay controlling by its contacts the bell circuit, is bridged across the line at each station, a condenser having first been introduced into its circuit. The various bells, sensitive respectively to either positive or negative impulses alone, are then connected through the relay contacts from the line to ground, one bell of each kind being used for each side of the line, or four in all. Now, when considerable and variable potential differences exist between the various station bell grounds, at times the direct currents in consequence thereof flowing through the bells will completely overpower the selective signalling currents and either cause failure of action or false signals. Mr. Stryker's scheme for overcoming the defect is shown diagrammatically in Fig. 2. It will be at once seen that the relative position

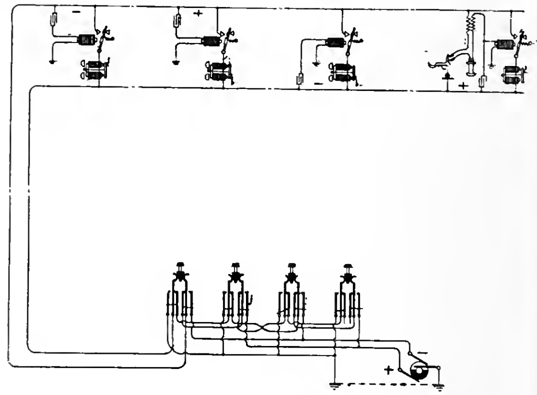

FIG. 2.—STRYKER SELECTIVE SIGNAL SYSTEM.

of bell and the relay and condenser, have been changed, the relay circuit alone being grounded. As the relays at all stations must operate on both impulse currents, whether positive or negative, the presence of a condenser in the relay circuits is of no effect, except to overcome entirely the flow of direct currents due to earth potentials. The bell-controlling relays may be any one of several special types which have been heretofore described in these columns. The American Telephone & Telegraph Company has been assigned the patent for this system.

A second system is that of Messrs. N. S. McKinsey and A. R. Nelson, of Susanville, Cal. This is what might be called an automatic step-by-step system, for all the various operations of selecting and calling a desired subscriber follow automatically the natural events of instituting a connection. Thus, the removal of a calling subscriber's telephone from the switch-hook at once so manipulates the apparatus at all other stations, if the line be not busy, as to give him absolute control. The depressing of a push-button moves synchronously all selective switches, and in addition connecting the stations to the line one after the other. In addition a dial apparatus indicates automatically just which subscriber is connected to the line at any instant. When the indicator shows the desired line, the release of the push-button stops all selectors and rings automatically the desired subscriber, while his response by lifting his receiver stops the ringing and completes the talking circuits. As soon as the conversation is completed, the apparatus all restores to normal upon the return of the calling subscriber's telephone to the switch-hook. It seems rather too bad that such a comprehensive system must depend for any of its functions upon a spring-driven clockwork.

Mr. Robert Hamilton, of Milton, Mass., is the patentee of the third selective device, his invention being directed principally to means for clearing out a line arranged for step-by-step selection. The return of the receiver to the hook at the calling station restores at once all selectors.

TELEPHONE CABINET.

Mr. W. B. Altick, of Lancaster, Pa., has patented another type of sliding-front telephone booth in general cross-section somewhat similar to his last preceding one. As in that roof, floor, backboard and half side pieces are provided rigidly fixed together, while the whole front may be slid away to permit of entrance. In this latest design there is laid out a spiral track on both roof and floor, this track having a length of approximately one and one-third circumferences, with the overlap in the rear of the booth. The sliding front, in two parts, is curved, so that it may easily slide in the track, from the rear of the booth, where the two parts overlap, to the front, where they abut. Packing pieces of flexible material secured to the forward edges of the stationary sides help to seal the booth to make it more impervious to outside noise.

SECRECY SYSTEM FOR COMMON BATTERY SWITCHBOARDS.

Many telephone users hesitate about mentioning confidential matters over the telephone because of fear lest the operators overhear them. It is evidently with an idea of reassuring such persons that a secrecy system, patented by E. H. Smythe, of Freeport, Ill., has been brought out. The system in its present form is adapted to cord circuits on the common battery system, wherein two supervisory signals are used, and the exclusion of the operator from the circuit during the existence of a conversation is accomplished by a differential relay. The tops to the operator's set are carried from the listening key through the contacts of the relay, which is of the two-circuit "cut-on" type; that is, when energized the contacts are closed. Of the differential relay windings, one is associated with the answering plug supervisory and one with the calling plug. Therefore, when both supervisories are out, as during conversation, the operator's connection to the listening key is severed by the de-energization of the relay, and again when both lamps are lighted, showing both parties to have hung up their receivers. When, however, one lamp only is lighted, the condition during the completion of a connection, the relay will be energized, its contacts closed, and the operator able to respond to the subscriber. The Western Electric Company has obtained this patent by assignment.

A NEW STRIP SPRING JACK.

Mr. Merritt S. Conner, of Chicago, has produced a spring jack strip quite novel in that no supporting plate is used, the front thimble supporting strip and the rear spring supporting strip being held together solely by the thimble connection strips. These latter are, of course, of extremely strong construction and the spring supports are built up upon them to form a rigid whole. With his type of construction Mr. Conner is able to readily space his jacks upon 5/16-in. centers on 5/16-in. strips, the jacks being designed for three-wire cord circuits.

SOME TRANSMITTER IDEAS.

Magneto transmitters are, of course, rather out of date. Nevertheless, a patent for one of new design has recently appeared, the inventor being M. C. Burt, of Chicago. In this transmitter a series of concentric cores and coils is used, forming together a compound electromagnet. In order to regulate the intensity of the generated telephone currents, a controller is provided, by means of which one or more coils may be switched from the circuit.

J. A. Williams, of Cleveland, Ohio, has introduced a spring within the casing of his transmitter, which is of the granular carbon, inertia type, to hold the back electrode flexibly to the annular support of felt upon the rear of the diaphragm. He has patented his invention and assigned the patent to the Williams Telephone & Supply Company.

A speaking tube extension for telephones forms the subject of a patent granted to J. J. Nye, of Brookfield, Vt. This is a speaking tube apparatus terminating in one end in mouthpieces designed to receive a telephone bell, a transmitter and a receiver. If a signal arrives on the bell it will be heard wherever the speaking tubes extend, while it is the idea of the inventor that response to the transmitter and the sounds from the receiver may also be made and heard, respectively through the same means.

SANITARY ATTACHMENT.

A book of perforated paper sheets, each of which is adapted to be placed over the mouth of a transmitter, forms the basis of a patent granted to H. L. Thompson, of Waterbury, Conn. The sheets are rectangular in section and the corners are ruled diagonally, so that they may be easily folded to grip the transmitter mouthpiece and thereby retain the paper sheet across its face.

TELEPHONE SUPPORT.

Another receiver supporting arm has appeared in a patent issued to G. Königstein, of San Francisco. This support has the now usual mechanical attachments to the hook switch to manipulate it when the receiver is not in use. Moreover, an additional manually-operated lever for manipulating the switch-hook is provided.

PEARNE TRANSFER PLUG.

A few weeks since we had occasion to notice a patent granted to F. D. Pearne for a switchboard plug containing within its shank a mercurial switching device. In the absence of detailed information, it was suggested in our comment that such switching device was probably for the control of supervisory lamp circuits. This we have learned from the manufacturer of the plug was erroneous, in that the lamp which is controlled is that of a transfer, for which type of circuit the plug is primarily designed. It was also suggested that the use of four strands in that very vulnerable part of the switchboard, the connecting cord, and the dependence upon a mercury contact might prove of serious disadvantage. Both of these suggestions were based upon experience in telephone operating. We are glad to hear, however, that no troubles of this kind have been found by the manufacturer in his experiments with the plug, which we understand have extended over a period of one year.

Radium in Treatment of Blindness.

The following is from the European edition of the New York *Herald:*

"About a month ago the German press announced that Prof. London was occupied in St. Petersburg in ascertaining the effects of radium rays on blind eyes, and that he had hopes by this means of restoring the power of sight. As the Emperor William evinced considerable interest in the professor's researches, the Minister of Public Instruction requested Prof. Greeff, director of the eye clinic at La Charité, to study the effects of radium on healthy and diseased eyes and report thereon.

"In the last number of the *Deutsche Medicaler Wochenschrift,* Prof. Greeff describes his experiments. As regards the effect of radium on healthy eyes, he shows that this is first apparent when the radium preparation is brought within about 10 cm. of the eye. The eye then suddenly becomes aware of a strange, faint, pale green luminosity which gets dimmer as the preparation is withdrawn. The patient is unable to say whence the rays proceed. At the beginning of the illumination the retina is not immediately affected by the rays —the effect of light is created by the fact that certain parts of the eye, especially the crystalline lens, are rendered fluorescent by the radium, and of this the retina becomes conscious. In regard to the action of radium rays on blind eyes, says Prof. Greeff, we must, before all, take into consideration their condition—whether completely sightless or still in possession of some remnant of vision. The latter are generally classed as blind because their powers of sight are so limited that they are, for all practical purposes, the same. Physiologically, however, there is a considerable difference in so far as in one case there is a consciousness of light, in the other none.

"Prof. London neglected to test the patient's consciousness of light in each case, whence it followed that the blind persons whom he tried with radium rays furnished negative or contradictory data. If by chance he fell upon a patient who still possessed a vestige of sight, the patient was able to perceive the effect of the radium. Prof. London then tried, by presenting shadow pictures, letters, etc., on a transparent screen illuminated by radium to bring these objects within comprehension of the blind patient. By this means the eye of a blind man still able to distinguish light from darkness gained the sensation of being able to see large objects. This sensation—and this is the decisive factor—can be also obtained by the substitution for the radium and the fluorescent screen of a petroleum lamp and a dark shade. He has, therefore, come to the conclusion that radium rays have no specific effect."

CURRENT NEWS AND NOTES.

RADIUM IN COINS.—A special dispatch from London of April 16 says: "The amount of radium to be procured in London to-day is less than a grain, according to the *Pharmaceutical Journal,* which suggests that chemists follow the example of one who obtained a small tube of five milligrams of radium bromide series out of half a crown in an hour." This has a rather apocryphal sound.

SHADOW CLOCK.—To Prof. Hirth, of Munich, Bavaria, is attributed the invention of an ingenious clock for night use. The invention consists of a lamp, which, on a button being pressed, throws upon the ceiling an optical representation of a small watch lighted by electricity. The figure is sharp and distinct and is enlarged to the size of a church clock. Such a device would find especial application in the sick room.

LATEST POPULATION FIGURES.—The United States Bureau of the Census has decided to make annual population estimates and has just issued a bulletin for 1903 for 438 cities and towns. These figures are useful for many statistical purposes. The total population was estimated to be just short of 80,000,000. New York City alone is estimated to have 3,716,139 inhabitants, or about 280,000 more than it had three years ago. To Chicago, which in 1900 contained 1,698,575 inhabitants, 1,873,800 are at present attributed. St. Louis, which had 575,238 in 1900, has since managed to pass the 600,000 mark, and Boston has nearly reached it with 594,618—about 34,000 more than it had three years ago. If such suburban towns as Cambridge (98,444) and Somerville (68,000) were incorporated with the city, the population of Boston would be not far from 800,000.

CITY OWNERSHIP IN CHICAGO.—In his message to the Chicago City Council, after the recent referendum vote favoring municipal ownership of the street railways, Mayor Harrison advised strongly against an immediate trial of city management and against the proposition to take up the business of the Chicago Passenger Railway Company, whose franchises are expiring. If the comparatively small mileage of that company could successfully be conducted by the municipality, the properties of the Union Traction Company and of the Chicago City Railway Company could then be taken over when their franchises lapse. But Mayor Harrison objects wisely to this and says: "If the idea be by this means finally and effectively to inaugurate general public ownership of all the traction utilities of the city, the suggestion is utopian rather than practical." He proposes as more sensible a new contract with the traction companies calling for the surrender of rights claimed under a legislative act of 1865 granting ninety-nine-year franchises, and providing that the money received as compensation be turned into a sinking fund. At the end of ten years this sinking fund is to be used in the purchase of the lines.

GOVERNMENT TELEPHONY IN PARIS.—A cable dispatch from Paris of April 16 says: "The telephonic war in Paris is causing no end of excitement, and for the moment every one has forgotten the war in the Far East. It is notorious that Parisians are at the mercy of the telephone service. They have worn the yoke of imposition and oppression so long they have almost ceased to complain. The 'Hello Girl' of New York is a dream of perfection compared with the article in Paris. The subscriber is very small fry in the latter's estimation, not worthy of consideration. But at last the worm is showing a disposition to turn, and the time seems to be at hand when the 'man who pays the freight' can hope for better treatment. In the first place the subscriber must buy his instrument outright. It costs him about $40. Then he is required to pay a quarterly rental of $20 in advance. As an instance of the treatment generally received by subscribers the case of Mlle. Sylviac, a well-known French actress, may be cited. She was breakfasting a few days ago with a friend at her own home when she found it necessary to use her telephone. She called for three-quarters of an hour before 'central' responded. Mlle. Sylviac rebuked the girl and the latter gave the actress an insolent reply. Thereupon she called up the superintendent and reported the 'hello girl.' The superintendent defended the employee. The actrss said the girl had talked to her in language like that of a vulgar milkmaid. The next day Mlle. Sylviac received notice that she could no longer have the use of the telephone unless she apologized to the telephone girl. The actress discovered later that the number for which she had asked had not been called up at all. She immediately instructed her lawyer to begin an action against the government to compel it to restore her telephone rights. She is backed by all the Paris newspapers, one of which says editorially to-day that it is a wonder the public does not resort to an axe instead of language in rebuking the insolent employees of the government staff."

LETTERS TO THE EDITORS.

Reciprocating vs. Turbine Engines.

To the Editors of Electrical World and Engineer:

SIRS:—We are certainly much indebted to Mr. Seymour for the valuable data presented in his article entitled, "The Economy of the Reciprocating Engine at Light Loads," appearing in your issue of April 2, particularly in relation to the losses in a high-grade engine type unit at various loads. The results which are shown are of great interest, and represent an excellent performance justly gratifying to any engine builder. It would seem, however, that a little more light thrown upon the above interesting subject from so authoritative a source would be generally appreciated. From the title of the article it was naturally expected that specific data upon actual performances might have been presented, rather than that conclusions should have been drawn from performances of other engines, the test conditions of which are not presented, especially as a rigid comparison has been made with a specific certified test of a turbine unit under loads ranging from less than 1/6 load to 60 per cent. overload.

Although the data given appear to be authoritative in every respect, it is, nevertheless, unfortunate that more than two observations were not given from which the character of the water rate curve might be determined, especially its extremes corresponding to overload and underload, which are in reality the object of the discussion. It is true that in Fig. 2 total losses have been given based upon tests of a similar engine unit, but *these losses are expressed in terms of total losses at full load,* instead of in terms of indicated horse-power, so that no information is at hand concerning the indicated steam consumption of the engine from which the general form of the water rate curve under half load might be determined. Much information might also be derived from the curve of total water consumption, from which observed results should be given as well as derived results.

Mr. Seymour states that his water rate curve is plotted from acceptance tests by Messrs. Moulthrop & Curtiss, and later that the results of No. 8 engine have been excluded "on account of conditions which prevented correct economy of the engine from being obtained." The average economy of the two engines tested by Messrs. Moulthrop & Curtiss was 12.15 pounds per indicated horse-power, which is not as good as that quoted in the article—11.54 pounds per indicated horse-power—although the curve shown is said to be based upon the former independent tests.

For electric lighting engines with ratios of approximately one to four, the lowest steam consumption per indicated horse-power usually occurs at about .75 to .8 full load. On curve C the point of lowest steam consumption per electrical horse-power appears about .7 load, from which we would gather the point of lowest steam consumption per indicated horse-power would occur at about .63 load. The rating is stated to be upon a basis of 165 pounds pressure and 27-in. vacuum, whereas the tests were made under 160 pounds pressure and 25.6-in. vacuum. As the lowering of the vacuum 1.4 in. and the pressure 5 pounds will lower the power of the engine for a given cut-off by about six pounds, or 2¾ per cent. of the pressure, it would be of interest to know the basis upon which the curve C has been plotted, as this materially affects its position with reference to the scale of abscissæ.

The object, however, for which we particularly beg space in your columns is to correct some inferences that might be gathered from the remarks Mr. Seymour has made regarding the steam turbine.

At the outset Mr. Seymour states "that the ideal engine should expand to back pressure, but to do this in an actual engine would load it much below its economical point." This is true, but it is a small part of the story. Were the engine to expand to the pressure of the vacuum, the increase in bulk and in losses, due to friction and cylinder condensation, would more than nullify the increase in internal economy, due to greater expansion ranges. In practice, the reciprocating engine for power purposes does not expand below 5 pounds, or 1/3 vacuum, whereas the turbine readily expands down to condenser pressure.

In his comparison, Mr. Seymour has missed an important feature of the turbine—that it may be run at full load with its best economy —whereas the engine must be run at about 25 per cent. underload to secure its best economy. He says:

"Central station managers will hardly consider it practical to run steam turbines at their most economical loads without a greater overload capacity than it is proposed to give them where the station load is a fluctuating one."

The published results from which he draws his conclusions show that the turbine under consideration carried 60 per cent. overload when operating under the lowest vacuum at which the machine was tested, and at this overload its economy was only 5 per cent. higher than at full load. All Westinghouse-Parsons turbines are capable of carrying overloads considerably beyond the capacity of the generator when operating under their usual conditions, and they will also carry full load when operating without vacuum. Moreover, in the turbine unit, the points of best efficiency of turbine and generator coincide, while with the engine unit the generator operates considerably below its point of best efficiency when the engine is giving its best economy. If, then, the turbine under consideration possesses an overload capacity commensurate with the engine and one that is suitable for the most exacting demands of fluctuating loads, why, then, should not the points of best efficiency of engine and turbine be more nearly superposed for proper comparison of water rate curves?

From the form and position of the curve C, it would appear that the engine under discussion is somewhat overrated. Furthermore, Mr. Seymour states, "In the case of a turbine, a very high vacuum is necessary in order to maintain either its capacity or its economy."

Although this may be said of some types of turbines where surface friction constitutes one of the most important sources of loss, it is not true of the type of turbine under discussion, as shown by the tests given by Mr. Mattice and by others. Naturally, the capacity and economy of the turbine is reduced by a lowering of the vacuum in precisely the same manner as the reciprocating engine. A reduction of boiler pressure would result similarly, but in the Westinghouse-Parsons turbine, the losses due to these sources are not so serious as might be inferred from Mr. Seymour's remarks; for instance, the economy will not fall more than 3 per cent. or 4 per cent. for each inch of vacuum down to a reasonable limit, say 25 in.

Pittsburg, Pa. Francis Hodgkinson.

Output of Rotary Converters.

To the Editors of Electrical World and Engineer:

Sirs:—An editorial in your issue of April 9 takes up the subject of rotary converters and their increased output over that of corresponding direct-current machines. It refers to the fact that this increased output is due to conditions existing in the rotary which keep down the armature losses, and incidentally mentions Messrs. "Steinmetz, Child and others" as having investigated this subject, the mention being made in a manner which seemingly credits the gentlemen named with being the first investigators along these lines.

In the issue of your paper for June 15, 1895, is an article written by myself in which the output of polyphase (including single-phase) generators and rotary converters is discussed relative to the armature copper losses, or heating, and with particular reference to the manner in which such losses vary when different numbers of phases are employed. This paper is, to the best of my information, the earliest published discussion of the subject with which it deals. The ground which it covers has been gone over in subsequent articles, in many cases employing an analysis practically identical with mine, but giving me no credit whatever. It seems only fair that your attention should be called to this fact, as some of the papers mentioned have appeared in the columns of your journal.

Out of the investigation on which my paper was based resulted my invention of the six-phase rotary in which the output is greatly increased over that of a three-phase rotary by the simple and comparatively inexpensive expedient of using three additional collector rings. A number of patents embodying variations of this invention have been issued since mine, but my original scheme is, to the best of my belief, the one now most generally used. It may be pertinent to add in this connection that the device further mentioned in your editorial and in the article by Mr. Baum of using artificial reactance in the compounding of rotaries, was also patented by me and under my patent it is controlled in this country to-day.

New York. Ralph D. Mershon.

The Inventive Faculty.

To the Editors of Electrical World and Engineer:

Sirs:—Your valuable and well-composed editorial in the issue of March 19 has been considered. Mr. Dooley once observed that the Supreme Court decided:

1st. The prisoner is guilty. 2d. The prisoner is not guilty.

I well remember the decision to which you referred. Condensed, it might read: 1st. Claims 2, 3 and 10 are void because not exhibiting an exercise of the inventive faculty. 2d. We cannot define what constitutes an exercise of the inventive faculty.

It is plain to me that the court lacked inventive faculty, if it could not render a better decision than that. I generally admire their opinions, but that one was too much for me. It is about as if they should decide: 1st. The man is guilty because he lied. 2d. We do not know what a lie is.

To come to the practical point, which is of definite value to the many well-known inventors among your readers, some of our brightest engineers are often puzzled as to whether their invention is of a patentable nature or not. The question of inventive faculty only presents itself when the construction is on the dividing line between engineering design and patentability. There are many definite principles of invention, some of which are as follows:

1. The accomplishment of a result previously thought practically improbable. Examples: The telephone, wireless telegraphy, the Pupin choking magnet system, and in general any pioneer invention creating a new art.

2. A construction saving labor, time, material or anything that is valuable. Examples: Micanite, which makes use of scrap mica; dies for stamping out blanks, instead of cutting them by hand, and Matthew's photometer, which saves the time of calculating.

3. Succeeding commercially in accomplishing what others attempted. Examples: Incandescent electric lamp and Nernst's lamps, Tesla motor, etc.

4. Simplifying. Examples: Doing away with overmuch mechanism, as in electric regulators, meters and other devices which are continually improved in this respect.

5. Converting manual into automatic devices. A high type of invention. Examples: The penny-in-the-slot machines, electric cutouts and typewriters.

6. Detail improvements. This is the most prolific field of all. Examples: The thousands of devices now in use are more truly improvements than pioneer inventions. It is the improvement that puts an invention on the market, makes money and often promotes comfort. Those that are becoming ripe for a new field are steam and gas turbines, wireless telegraphy, polyphase-current regulators; X-ray apparatus, now that tumors and cancers are being treated and often healed; photometers, etc. Just when we think a device is about perfect, behold, a new and valuable improvement appears.

There are several other rules I have thought of, but I will not take more of your precious space, as my object was to remind your inventors that the Supreme Court decision, as is often the case, related to an invention on the dividing line, where naturally patentability is more a matter of opinion than evidence. Consequently, the court is usually not unanimous, and the several judges of the lower courts have made all the claims alternately void and valid, and so on, indefinitely, from court to court. There are thousands of money-making patents that have never even appeared in the courts, because they are not on the dividing line. Although there are worthless patents, yet the general rule is that the patent is valuable if the invention is valuable, provided, of course, the claims in the patent properly protect the invention. The claims are the heart of the patent. They are highly technical definitions of the invention as distinguished from the device, each one progressively subordinate to some other one of the same group, and all interwoven upon predetermined and complex forms.

New York. Edward P. Thompson.

Individual Motor Drive.

To the Editors of Electrical World and Engineer:

SIRS:—I have read with great interest the discussion of "Individual Motor Drive" in your issues of March 12 and 26, by Mr. W. Cooper and Mr. H. H. Cutler, and have been greatly impressed by the forcible argument of the former and the sensible argument of the latter gentleman.

It would clearly appear from the article of Mr. Cutler that the variable-voltage system has no advantages over the variable-flux system of speed variation as to the size of the frame of the motor used. The writer thinks that Mr. Cooper has taken his stand with the utmost sincerity in the article of March 26, but even the most sincere belief may sometimes be wrong.

The three principal conditions of designs to meet the requirements of variable speed by variable flux are, namely, good efficiency and absence of sparking and heating. These conditions are only to be met by careful design. A standard motor generally has too high normal speed to permit of its being speeded up to any such extent as, say, 3½ : 1. We will take, for instance, a 220-volt, 15-hp motor running at 700 r.p.m., which is a standard with a certain prominent company, with core dimensions of 11 in. x 9 in. This motor has a peripheral speed of 2,000 ft. per minute at 700 r.p.m. and the speed variation of 3½ : 1 would make a peripheral speed of 7,000 ft. per minute, which would be excessive. However, a speed variation of 2 : 1 would be permissible and is very readily given with the standard machine. We may, however, reduce this speed from 700 to say 450 r.p.m., and with 3½ : 1 ratio, the maximum speed of 1,570 r.p.m. would not be excessive.

Now, according to Mr. Cooper, this motor would only deliver 2¾ hp with the flux reduced to bring the speed to 1,570 r.p.m. and could not be made to maintain 9.6 hp from 450 r.p.m. to 1,570 r.p.m. without sparking or without giving unsatisfactory operation in general. Now, as a matter of fact, this motor with armature designed to reduce the speed to 450 r.p.m., and with constants for variable flux design, has, from actual test on a 220-volt, two-wire system, given 10 hp at 450 r.p.m. and 10 hp at 1,570 r.p.m. without sparking, heating or having poor efficiency and, I may add, without the use of any hypnotic influence brought to bear on the motor whatever. The temperature rise of the parts of the motor in question after a six-hour run with full load (10 hp) and full field was as follows: Armature, 26° C.; commutator, 23° C.; frame, 20° C.; pole tips, 28° C.; field, 28° C., with efficiencies as follows: Lowest speed—¾ load, 81 per cent.; full load, 84.5 per cent.; 1¼ load, 86 per cent. Highest speed—¾ load, 86.5 per cent.; full load, 88.7 per cent.; 1¼ load, 89.2 per cent.

The slowest speed of a motor of this kind represents the maximum heating and minimum efficiency condition of the machine, as the temperature of the parts and the total loss are greatly reduced as the speed of the motor is increased. This represents the actual results obtained from tests of a motor of this type designed by the writer.

Now, if it is desired to get a 4 : 1 ratio of speed variation, it would be necessary only to reduce the speed still lower and the horse-power correspondingly, which reduction of speed and horse-power would be equally true when using the variable-voltage system. But it would be necessary to give an increased number of armature conductors to the armature in the variable flux machine to lower the speed and would give a corresponding reduction in horse-power output, as in the variable-voltage system; the difference in the two systems being that the variable-voltage system increases the horse-power with the increase of speed, while the variable-flux system keeps the same horse-power for all speeds, the frame of the machine remaining the same. For instance, if in the variable-voltage system it is wished to get, say, 7½ hp at 350 r.p.m., the armature of the machine would be designed for 30 hp at 1,400 r.p.m., 220 volts under the normal flux. By having the voltage reduced on the armature to 55 volts, it would then give 7½ hp. Now, with the variable-flux system, the armature would be designed for 7½ hp at 350 r.p.m. and be speeded up by means of field resistance to 1,400 r.p.m., maintaining 7½ hp at the different speeds.

There is a point in favor of the latter system which may or may not have been brought out before, and it may be here stated to advantage. In changing the voltage to the next higher step on the variable-voltage system, the motor responds to the change in applied voltage by a jump, which is rather hard on gears and pinions and on the cut being taken by the tool. The surge of current is hard on the controller, to say nothing of continual rack on the machine tool.

The change in the speed of the machine tool by the variable-flux system is smooth, for when the resistance is inserted in the field the motor does not immediately jump to the new speed, as the flux does not immediately respond to the removal of a part of the magnetizing force, but meets the new conditions without jar or jerk and the increments of speed made as desired by the number of steps of the field rheostat.

I believe Mr. Cooper admits, however, the superiority of the variable-flux system for speed variation, providing satisfactory motors can be built. These motors, while they are comparatively easy to design, must be made with very good sparking constants, which constants must be calculated at the maximum speed as the extreme condition, then the heating and efficiency calculated at the minimum speed. When a motor satisfies the two extreme conditions, it clearly will be satisfactory between the two limits.

MILWAUKEE, WIS. WM. J. HENSLEY.

Technical Education.

To the Editors of Electrical World and Engineer:

SIRS:—Your editorial of March 26 on "British Technical Education," and Mr. Del Mar's letter in your issue of April 9 somehow seem to reopen an old and much-worked field for discussion.

Mr. Del Mar's experience with that "M. I. T." graduate is rather unfortunate, inasmuch as Mr. Del Mar appears to have arrived at the conclusion that the course at Technology is essentially practical —which it is not. The school is primarily for the education of the specialist, and the courses are devoted very largely to the theory of each particular field. No technical school can pretend to turn out finished engineers. They are the great preparatory courses for the school of experience which is, and must always be, the most important part of education.

I well remember some words spoken by the late Dr. Walker to a Freshman class. They were to the effect that "Technology" did not and could not, nor could any other school, "turn out" finished engineers. "We try," he said, "to give you the tools with which to learn your profession. We try to train your minds to so grasp the meaning of phenomena that you may turn it to practical account, so that the experiences with which you hereafter meet and which will constitute your engineering education—these actual working facts—will have for you a significance that they cannot have for the untrained mind."

This, and this alone, constitutes the meaning and value of a technical education. The degree a school confers means no more than that its recipient is ready to learn. The field of his mind is plowed and fertilized and ready to receive the seed of practical experience. The possession of a degree does not, however, mean that a man is capable of eventually becoming an engineer. He may make a more or less futile attempt—witness the crowds of the Ph. D's and B. S's in our draughting rooms; men plugging away year in and year out for a pitiful pittance. These men, one finds, usually lack that vital quality of soldierly confidence, the quality of push and hustle, the quick-wittedness which is the supreme gauge of the human race.

It is this very point of quick-wittedness which our schools should seek to develop—to train a man so that his mind can act in many fields; to keep him out of a rut; to broaden him so that he may appreciate and harvest up the salient facts in every work with which he comes in contact.

Teach him broadly first. Let him study languages, literature, history, botany, music—whatever he likes. Give him a chance to learn and know of the great thoughts and great minds that have made our world a half-way decent place in which to live. Then, if you like, the essential laws that govern all engineering, provided he has still retained the thought that he would like to be an engineer. Bring him in contact with everything he can grasp. Because he particularly likes electricity, is that any reason he should not have some surveying? No one ever knows when he may need it, even if ever so elementary a knowledge. His experience in other things will teach him how to build on this.

The trouble with nine-tenths of us is that we have got between two walls of the densest ignorance which cut off all our horizon and make life a despicably little path that leads to nothing—for the future is nothing. It is right here, right now, that we must live, and the man who is free to roam the fields and look abroad, who gets the tone of the picture and worries not too much over the quality of the paint, is the man who succeeds in life. The world is a place in which we work to live and do not live to work.

Is it not interesting that the men who hold positions of trust—the great men of the world—are and always have been men of the broadest education?

You will say, perhaps, that but few men are suited for this general education. At school we know men cut, and as far as possible reduce to a minimum, all subjects extraneous to their specialty. Well, make our professional schools elective, at least in part. Broadness in education is essential for the best work, and give the men who appreciate this an opportunity to spread out. Start by cramping and the man is stunted for life.

There is all together too much haste in our engineer factories. They manage this thing better in the law and in medicine, where a man must have a preliminary education of some scope before he can gain admission to the professional school. But in engineering we find white-faced boys fresh from their A, B, C's, who know absolutely nothing of life or of the serious side of work and who treat the whole problem as more or less of a spree. How in the world is such material in the short space of four years to be taught the wisdom of Solomon?

New York. Bassett Jones, Jr.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Electric Resistance of Bearings.—Zorawski.—A communication referring to an article of Kennelly and Adams, published in Electrical World and Engineer, February 7, 1903 (Vol. 41, page 231). These authors had tested the resistance of bearings of the usual self-oiling type, with two revolving brass oil rings in each, and had found that the transition resistance between shaft and pedestal was practically zero when the motor was at rest, but became very high when the motor was revolving. A 6-kw Edison dynamo of 1,800 revolutions was found to have at 100 revolutions a resistance of bearings of 4.4 megohms. The present author remarks that these results seem to be in disagreement with the fact that several firms in Continental Europe build three-phase induction motors with a similar type of bearings with only two slip rings, while the terminal of the third winding is connected to the axle and the terminal of the corresponding starting resistance to the motor casing. The author has himself made experiments with a 16-hp, three-phase induction motor of this type, and the transition resistance was found to be 0.00121 ohm when the rotor was at rest and 0.00158 ohm at a speed of 960 revolutions, the dimensions of the bearings being diameter, 42 mm.; length, 110 mm. The author suggests that the reason of the discrepancy may be in the kind of oil used. In the machine tested by him ordinary mineral oil of high fluidity was used. —*Elek. Zeit.*, March 31.

Rotary Converters.—Lincoln.—An illustrated article in which the author discusses in a very simple way the voltage regulation of rotary converters. A series coil on a rotary converter has the effect of automatically changing the ampere-turns applied to the field. Varying the field ampere-turns means varying the magnetizing element of the alternating current delivered to the collector rings, causing the current to become leading when the ampere-turns are more than normal and lagging when the ampere-turns are less than normal. The voltage across any inductance in circuit tends to subtract from the generator voltage when the converter current lags and tends to add to the generator voltage when the converter current leads. The conditions for rotary converter compounding are, therefore, (*a*) a series winding on the rotary converter connected so as to assist the shunt, (*b*) inductance between the generator and rotary converter. The series field coils in a rotary converter do not increase the voltage directly as in a direct-current generator, but indirectly, through co-operation with inductance in the supply circuit.—*Elec. Club Jour.*, March.

Rated Speed of Motors.—Esson.—A communication criticizing some points in the paper of Hobart recently abstracted in the Digest on the rated speed of electric motors, as affecting the decision whether direct-current or induction motors should be employed for a given speed. The author agrees with Hobart's conclusions concerning the case for alternating versus continuous current as regards the motors, but he points out that, in deciding in favor of one system over another, it is also necessary to take into account the cost of generators, wiring, stators and of other equipment. Which side the consideration of these further factors would favor depends on circumstances. Most installations have a mixture of big and small motors, several different sizes running at different speeds, and this, together with the presence or absence of the necessity for speed variation, would influence the decision as to what type of motor should be installed.—Lond. *Elec.*, April 1.

Sine Currents.—Ruedenberg.—In order to produce pure sine currents, it has formerly been suggested to make the pole shoes of the field magnets of such a shape that the curve of field induction, as a function of the points of armature circumference, approaches as much as possible a sine curve. The e.m.f. which is produced in the armature wires while they pass through this field is then also a sine wave. However, when the machine is loaded the sine curve is distorted. The author, therefore, suggests a different method, which is independent of the load of the machine. By developing the wave mathematically in form of a Fourier series, he shows that a certain number of the higher harmonics can be made zero simply by properly choosing in advance the type of winding of the machine. However, in such machines the utilization of the material is less favorable, yet the method should be useful in special cases in which the production of pure sine currents is of importance.—*Elek. Zeit.*, March 31.

Induction Motors.—Behn-Eschenburg.—The conclusion of his long paper on magnetic dispersion in induction motors, and its influence on the design of this machine. The author gives a basis for the design of induction motors and suggests that for a rapid determination of the characteristic curves of the motor, five cases should be discriminated which correspond directly to five points on the load curve, and which suffice in general to characterize the motor with certainty. The formulæ for these five points are given and two numerical examples are added.—Lond. *Elec.*, April 1.

Heating of Induction Motors.—Punga.—A mathematical article in which he gives formulas for calculating the Joulean heat developed in squirrel-cage rotors.—*Zeit. f. Elek.* (Vienna), March 27.

Commutator.—A communication with detailed drawings of a former for copper connectors for commutator bars.—*American Machinist*, April 7.

Power.

Gas Versus Electric Power Distribution to Sub-Stations.—Smith.—A paper read before the Birmingham Section of the British Institute of Electrical Engineers. The author compared the two following systems: The first is the transmission of electricity from a gas engine station, situated under favorable conditions, at a distance of five miles from the center of the city, and its subsequent distribution by means of sub-stations. The second problem is that of a central gas producer station situated on the same side as the producer and electric station in the first case, with transmission of gas to sub-stations containing gas engines coupled to electric generators. A city of the size of Birmingham is made the basis of the estimates. The result at which he arrives is that gas transmission, in such a case, does not necessarily cause much more than one-half the cost of electric transmission by means of underground cables. Should his figures be compared with those for a steam engine station, and the probability of the gas mains being used for transmitting gas for heating purposes be considered, the advantages of using producer gas are yet more striking. The paper was discussed at some length and the opinion was expressed that many of the author's conclusions are based on absolutely theoretical figures, and that his estimates at best are only a sort of "pious hope" as to what might be accomplished with gas. It was also thought that the difficulties of transmitting high-pressure gas over long distances were not sufficiently appreciated.—Lond. *Elec.*, April 1.

The Use of the Earth as Return Conductor.—Pionchon.—A description of experiments made in the Isere Valley on the use of the earth as return conductor. The experiments were made with a six-pole, 250-kw, 600-volt, direct-current generator in a hydroelectric plant in Lancy. This machine was connected by a 8-mm. isolated copper wire with a receiving apparatus in the open air at a distance of 1.7 km., near Crolles. The negative pole in Lancy was connected by means of a 19-meter long and 8-mm. thick copper wire to the water pipes of the turbine installation. The earth connection at the receiving end in Crolles was made by means of cast-iron tubes of 2.9 meters length, 16.5 cm. external diameter and 10 mm. wall thickness. With their whole length they were buried in the earth in a vertical position. A set of ten such tubes, arranged in a circle of 30 meters radius, formed one earth connection and another set of ten tubes were buried at a distance of 10 meters between each other and arranged in a straight line. Switches were arranged which enabled one to connect in series or parallel or disconnect several tubes at will. It was found that the resistance of a single tube was 10.75 ohms and the conductivity 0.092 mho. By adding a second, third, etc., tube, the conductivity is not doubled or tripled, etc., but is smaller than one would expect. If the conductivity of a tube is calculated as the mean of the conductivity of a set of five tubes one gets $0.3082 \div 5 = 0.061$ mho. In other tests the distribution of the potential in the earth was investigated; still other tests were made with alternating currents in order to determine the influence on telegraphic lines. There were no disturbances of such size that the regular operation of the telegraph lines was interrupted for a moment. Nevertheless, some disturbances were observed, but it was not quite clear that they were due to the use of the earth as return in the alternating-current transmission line. Further experiments in this direction are to be made.—*Elek. Zeit.*, March 31.

REFERENCES.

Gas Power.—Gow.—An article in which, after a brief discussion of the use of natural gas, illuminating gas, blast furnace gas, coke oven gas, and oil gas for limited applications of power purposes, he discusses at greater length the making of producer gas. He emphasizes that a gas engine and a producer plant to produce gas from any grade of fuel have passed the experimental stage; they are not engineering possibilities, but engineering achievements.—*Elec. Club Jour.*, March.

Electricity in Mines.—Guarini.—The first part of what appears to become a long illustrated serial on the various applications of elec tricity in mines. In the present installment the author discusses electric signalling and use of electric power for ventilation.—*L'Eclairage Elec.*, April 2.

Cranes.—Kann.—The conclusion of his illustrated description of various new types of cranes built by the Austrian Union Electric Company. A crane built for the Lloyd ship works in Triest, which is able to lift loads of 120 tons, is described in detail.—*Zeit. f. Elek.* (Vienna), March 27.

Wire Ropes.—Nearly the whole number is filled with various articles on the construction and uses of wire rope, especially in mining and metallurgical plants.—*Mines and Minerals*, April.

Traction.

A Single-Phase Railway Motor.—Bell.—A communication in which the writer deplores the action of the Westinghouse Company in recommending only 1,000 volts for its single-phase railway system. He believes it perfectly feasible to use much higher voltages than this, especially outside of cities. Referring to a former article of Renshaw, he states that a high power factor in a single-phase motor does not necessarily mean high efficiency—in fact, there may be a high power factor and a very low efficiency. To prove this he cites a case where he designed two induction motors. One of these had very poor iron and gave the higher power factor, although having a much lower efficiency than the other motor.—*St. R'y Jour.*, April 9.

English Electric Railway.—In a continuation of the description of the Liverpool-Southport Electric Railway, the method of train control is described in detail and profusely illustrated. The trains have a motor car at each end and generally two trailers between them. No multiple-unit system is used, but a direct system of control is obtained by coupling a few main cables from one end of the train to the other. This is called the dual method of control. A diagram shows in detail the controller, motor and reversal connections. One set of four couplings connects the motors and reversing switches on the rear motor car to the front controller, and the other set of couplings connects the front motor car to the rear controller. When the couplings are disconnected the two motor cars are independent, and nothing further than this is required for running them separately with any desired number of controllers.—Lond. *Elec.*, April 1.

Evansville & Princeton Traction System.—A description with map of this 47-km. interurban line built in Southern Indiana. Bracket construction is used in the country and span wire in the cities and towns. The electrical equipment consists of two 400-kw, 360-volt, three-phase generators. The two 30-kw exciters employed are also used to light the building. There is also one 300-kw rotary converter and three 125-kw, 400-11,000-volt transformers. The sub-station contains a 300-kw rotary converter and three 125-kw transformers.—*St. R'y Jour.*, April 9.

France.—A report on recent developments in French tramways and referring to the large amount of construction work now being carried on by the Metropolitan Railway. The Nice Tramways will build a new double line between Villefrance and Beaulieu, using 20 cars equipped with the multiple-unit control system—the first application of this system on French tramways. The Oporto Tramways has asked for estimates covering the cost of converting its system from direct current to alternating current. The East Parisian lines, which are operated principally by the surface-contact system, are in a very bad way, and it is very doubtful whether any more franchises will be given for surface-contact systems in Paris.—*St. R'y Jour.*, April 9.

REFERENCES.

Berlin.—Schiff.—The first part of a long and profusely-illustrated article on the construction and equipment of the cars used on the Berlin electric elevated and subway roads. The third-rail system is used with multiple control.—*Elek. Bahnen*, March, No. 6.

Los Angeles.—Another article in the serial on electric railways in and about Los Angeles, Cal. The present installment deals with the system of the Los Angeles Railway Company, which is purely a city system, embracing over 200 km. of track. Many details are given and illustrated concerning the rolling stock, car houses and operating methods.—*St. R'y Jour.*, April 9.

Installations, Systems and Appliances.

Architectural Design of Electricity Works.—A long editorial with reference to a paper read by Peach before the Royal Institute of British Architects. It is thought that the size of central stations is such that it is a great mistake to erect a building for them devoid of any architectural ornament. Peach even advocates the ornamentation of the chimney and showed among other photographs the elaborate chimney of the power station at Munich and the chimney of his own design in an English plant. The latter is 260 ft. high and of square section, 18 x 18 ft. inside, and a fairly heavy ornamentation in blue brick has been adopted for the upper part, the lower portion being left quite plain. "In the architectural treatment of the upper part an attempt has been made to take advantage of the iron bands which sooner or later are required round the upper part of all shafts, and of the recesses formed by placing the set-offs, when the brick work is reduced in thickness, on the outside instead of the inside of the wall. By these means some relief is obtained, and the upper part is designed as an enriched feature, which, in contrasting with a plain wall below, forms the whole composition." The question of external appearance is even of more importance in the case of large sub-stations in the center of a populous district. In England it has been the custom to have all the plant with the exception of the switchboard on the ground floor, and Peach still favors this plan. The small space occupied by turbine-driven machinery, however, renders it necessary to modify existing designs in the case of works employing this class of machinery. The foundations for the generating sets should have broad bases, large in comparison with the height of the foundation, and many recommend that the sides should slope upwards considerably, so that the area of the top is much less than the base. This concentrates the effect of the load towards the side of the block and prevents vibration about an edge, as frequently happens when the foundation is of plain square shape, like a brick set on edge.—Lond. *Elec.*, April 1.

REFERENCE.

British Central Station.—An illustrated description of the new electric station of West Ham. Originally current was used only for lighting, but the rapid growth in the demand for this purpose and the recent introduction of electric traction necessitated considerable additions. An entirely new station has been erected; the single-phase system of supply already in use for lighting has been retained, but a direct-current system has been installed for traction There are at present installed nine dynamos of an aggregate capacity of 6,300 kw. For lighting 2,000-volt, single-phase current is generated at a frequency of 50 periods per second, with a 110 and 200-volt distribution network.—Lond. *Elec.*, April 1.

WIRES, WIRING AND CONDUITS.

REFERENCE.

High-Tension Wires.—A note on the use of overhead high-tension wires in Californian cities, with a photograph of a street in Sacramento. Some remarks are copied from a Sacramento newspaper on the dangers of this policy and the demand is made to put the wires underground.—*Eng'ing News*, April 7.

ELECTRO-PHYSICS AND MAGNETISM.

Conductivity in Gases.—MERRITT AND STEWART.—An account of an experimental investigation of the conductivity produced in rarefied gases by an incandescent cathode. The incandescent filament discharged negative electricity even in the highest vacuum the authors could get. It seems probable that the electrons by which the charge is carried come from the incandescent body rather than from gases in contact with it. There is a striking resemblance between the behavior of an incandescent cathode and an illuminated cathode. In each case the phenomena are primarily due to the emission of negative electrons by the surface. In one case it is light, and more especially ultra-violet light, that acts as the agent to bring about the emission of the electrons. In the other case the high temperature of the surface produces the same result. At high vacuua the cathode ray particles are the sole carriers of the current.—*Phys. Rev.*, April.

Radioactivity.—STRUTT.—A Royal Society paper giving the results of tests of various minerals of North Carolina, Norway, Cornwall and Brazil. The method used was to heat the crude mineral and to examine the rate of decay of the emanation which it gives off. Each emanation has a characteristic time constant of decay, and by determining this we can identify it. He also examined the mineral water of Bath and found it highly active. He estimates the quantity of radium annually delivered by the spring to be about ⅓ gram. The volume of gas which the spring delivers is about 100 cu. ft. per day. About 1/1000 part of this is helium, so that about three liters of helium is given off daily, or about 1,000 liters per year.—Lond. *Elec.*, April 1.

REFERENCE.

Resonance.—TAYLOR.—An article, illustrated by diagrams, in which the author describes a simple method for attaining resonance in systems subject to electric oscillations of high frequency, and also describes some interesting lecture room demonstrations of phenomena peculiar to such systems.—*Phys. Rev.*, April.

ELECTRO-CHEMISTRY AND BATTERIES.

Capacity of a Lead Accumulator per Unit of Weight.—LOPPE.—A theoretical article in which the author calculates the very highest ampere-hour and watt-hour capacities which the lead accumulator can have per kilogram per total weight. The calculations are, of course, based upon the amounts of material required for the chemical action according to Faraday's law, and the following assumptions are further made: The "practical capacity" of an accumulator is two-thirds of the "total capacity" (the latter being the capacity, if the discharge is driven down until the e.m.f. becomes zero). For the ratio of the weight of active material to the total weight of the plates the high value 0.8 is assumed. For the calculation of the weight of the electrolyte he assumes that at the end of the charge the electrolyte has a density of 1.285 and at the end of a discharge 1.125. For the ratio of the weight of the total cell to the weight of plates and electrolyte together the low value of 1.15 is assumed. All these assumptions represent conditions under which the utilization of the active materials in the accumulator would be extremely high, so that the results at which he arrives represent maximum figures which one has to strive at in practice rather without hoping to attain them. He finds that under these conditions a total weight of 35.57 grams per ampere-hour capacity is required. This weight is the sum of that of the electrodes, 15.38 grams; electrolyte, 15.55 grams, accessories, 4.64 grams. For the maximum capacity per unit mass of a lead accumulator he, therefore, finds 28.1 amp.-hours per kg. and 53.39 watt-hours per kg.—*L'Industrie Elec.*, March 25.

Decomposition of Lithium Chloride.—PATTEN AND MOTT.—A very long account of an investigation of the decomposition curves of lithium chloride and the electrodeposition of lithium. The authors have discovered and used new classes of solvents for the electrolytic separation of alkali metals (such as lithium, sodium, etc.) and alkaline earth metals (such as magnesium, calcium, strontium, etc.), and other metals not easily obtained from aqueous solutions. They have found such organic solvents to be suitable which fulfill the following two conditions: First, there should be present in the solvent not less than three carbon atoms; second, one or more of these carbon atoms should be the center of a carbonyl group, or have bound to it an hydroxyl group. From their investigation of the decomposition of lithium chloride it appears that the process of electrolysis is essentially the same for all current densities. The residual current verges into the steady current because of the increased rate at which the solute is decomposed with increasing current density; the alkali metal, similarly, deposits on the cathode when the rate of decomposition of solute exceeds the rate of solution of the alkali metal. The low polarization in alcoholic solutions at moderate current densities is strong evidence that the alcohol is not decomposed by the current simultaneously with the lithium chloride. The solute is decomposed before the solvent, but it does not necessarily follow that the solvent takes no part in the conduction. These considerations, developed for non-aqueous solutions, are applicable to aqueous solutions as well. The single potential of lithium has been determined as 2.41 volts. The alloying effect of the cathode used—platinum—is a minor factor in decomposing alkali metals from solution, and the solvent which acts to a considerable degree upon the metal may be preferable to one which corrodes slowly, with the formation of a high-resistance film, as for example pyridine. High current density and consequently good conductivity are essential in so far as they may be needed to balance the solvent action of the solution upon the metal. High boiling point and latent heat of vaporization are more desirable in a solvent than very high heat of formation.—*Jour. Phys. Chem.*, March.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Phase Meter.—GRAU.—If an alternating-current wattmeter can be so arranged that for varying load the current, i, in the movable coil and the current, J_1, in the fixed coil are constant, the instrument would be suitable, not for measuring the power, but for determining the power factor. For this purpose the arrangement shown in Fig. 1 is used. The fixed wattmeter coil is made of manganin so as to represent a distinct resistance of a temperature coefficient practically

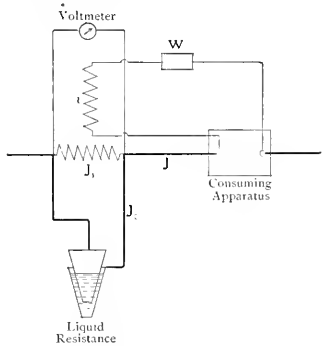

FIG. 1.—PHASE METER.

equal to zero, and its terminals are connected to a voltmeter for control. Since the resistance of this wire is constant within wide limits, the reading of the voltmeter may be used for determining the current in the fixed coil; if this reading is constant, the current, J_1, is also constant. In order to make J_1 constant and independent of the current in the consuming apparatus (motor, electric furnace, etc.), a liquid resistance is connected in parallel with the fixed instrument coil. By regulating the liquid resistance it can be accomplished that the current, J_1, remains constant while the current, J, changes. The current, i, in the movable coil is held constant by means of the rheostat, W, in series with it. Under these circumstances the reading of the wattmeter is directly proportional to the power factor, so that the phase difference may be easily found.—*Elek. Zeit.*, March 31.

Frequency and Slip Meter.—BIANCHI.—A note on a new device for measuring the slip of induction motors. The whole apparatus is self-contained in a box of small size. A small electromagnet, with a polarized armature, is connected in shunt to the line through a contact-breaker. The latter consists of a disc of insulating material having (for a bipolar machine) one metal contact piece on its periphery, the disc being directly rotated by the rotor of the induction motor to be tested. Every time this contact piece passes beneath the brush, the shunt circuit referred to is closed and the electromagnet is energized. Since the frequency corresponding to the speed of the rotor is lower than the frequency of the line, it follows that contact is made each time at a different point of the primary wave. Each successive contact corresponds to a slightly advanced value of the line wave. The electromagnet is, therefore, energized by a current wave of the frequency v, equal to the difference of the frequency of the line and the frequency corresponding to the rotor speed. Since the armature of this electromagnet is polarized, it will be actuated in accordance with this wave of comparatively low frequency. The number, N, of the revolutions of the rotor is recorded by a speed counter and the frequency, v, is recorded by means of the electromagnet. The slip in per cent. is calculated from the equation:

Slip $= 100\, v \div$ the sum of $v + \dfrac{p\,N}{60}$; and the impressed frequency is $v + \dfrac{p\,N}{60}$. In these equations $2\,p$ is the number of poles. If the induction motor has more than two poles, the rotating disc must have more than one contact; in fact, the number of contacts must be equal to the number of pole pairs. In Bianchi's apparatus, six different contact rings are provided, allowing motors with nearly every number of poles between 2 and 36 to be tested.—Lond. *Elec.*, April 1.

Measuring Self-Inductance.—DUANE AND LORY.—An article on the use of a "differential telephone" as a means of measuring a self-inductance with an accuracy of about 0.02 per cent. A differential telephone receiver is one, on the bobbin (or bobbins) of which two coils, $A\,A'$ and $B\,B'$, are wound side by side, as indicated in Fig. 2.

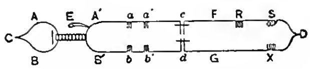

FIG. 2.—MEASURING SELF-INDUCTANCE.

By suitable means these coils are adjusted so as to have equal self-inductances and equal resistances, and so that the magnetizing effect of a current flowing through one coil from A to A' is exactly annulled by that of an equal current flowing through the other coil from B to B'. A variable self-inductance standard, S, is joined in series with coil $A\,A'$, and the coil of unknown self-inductance, X, in series with coil $B\,B'$. A non-inductive variable resistance, R, is inserted in series with S or X, according as the resistance of X is greater or less than that of S. The two entire circuits are then joined in parallel and an alternating e.m.f. is applied to the branch points, C and D. By varying R and S values can be found easily such that no sound is heard in the receiver. When this is the case the two parallel currents must be equal to, and in phase with each other, and, therefore, the self-inductance of X must equal that of S. Before the instrument is ready for use, three adjustments are necessary, but these may be made once for all; first, the equalization of the magnetic effects of the two receiver coils and second and third the equalizations of the resistances and self-inductances of the coils. In comparing the self-inductance of a coil, X, with that of a standard S, two balances must be made. The resistance of the parallel circuits must be made equal to each other by varying R, and the self-inductances equal to each other by varying S; one of these balances does not depend upon the other. If the divisions of the resistance box, R, are not small enough, the final balance of the resistances may be made by means of the sliding contacts, c and d.—*Phys. Rev.*, April.

Weston Cell.—BARNES AND LUCAS.—An account of an investigation of various types of Weston cells. From the results of their experiments it follows that cells with a solution, saturated at 0° C., have practically no temperature coefficient; that cells with a saturated solution of constant strength have a temperature change of 0.0038 per cent. per degree; that cells with moist crystals and a 13 per cent. amalgam have a temperature change of 0.0055 per cent., and that cells with moist crystals with a 14.7 per cent. amalgam have a temperature change of 0.008 per cent. per degree. The ratio of the Clark cell at 15° C. to the Weston cell at 20° was found to be 1.40666, which is coincident with the value found by Jaeger and Lindeck, of the Reichsanstalt, which is 1.40665. The authors think that it is a matter of small moment which cell, the Clark or the Weston, is adopted as an official standard, since the ratio of the one to the other is known so closely. Both cells have points to recommend them for different types of work, but it is evident that the Clark cell with its high temperature coefficient will retire more completely into the laboratory as time goes on, leaving to the Weston cell the more active part of a general working standard.—*Jour. of Phys. Chem.*, March.

Standardization of Notation.—STRECKER.—A very long paper read before the Berlin Electrical Society on a uniform notation of physical quantities. In the introduction the resolutions of the Chicago Congress, based upon the system of Hospitalier, are discussed. It is said that this system is well designed and has been found useful in electrical engineering, but that it does not meet the justified needs of the mechanical engineer. It is urged that in introducing a uniform notation no system whatever should be attempted, but freedom in the voice of the notation and consideration of existing usage should be the main points. The Berlin Electrical Society had sent out inquiries to their members with a request of making suggestions and the replies received are classified at great length. Finally the following list is given of such quantities about which there was the greatest uniformity of opinion: Length, 1; mass, m; time, t; angle and arc, $\alpha\,\beta$ . .; speed, v; number of revolutions, n; work (Arbeit), A, efficiency, n; pressure (force divided by surface), p; momentum of inertia, K; temperature, T; intensity of magnetization, T; magnetic field intensity, H; magnetic induction, B; magnetic permeability, μ; magnetic susceptibility, K; coefficient of magnetic hysteresis, n; e.m.f., E; current, J; quantity of electricity, Q; electric capacity, C; eddy-current constant, β; electric energy, A. This list is to be considered only as a proposition. A second list is then given concerning which the opinions were much more different, and which is, therefore, still more a proposition only. All representatives of pure and applied natural science of all countries are invited to participate in the discussion.—*Elek. Zeit.*, March 31.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Wireless Telegraphy Receiver.—KARPEN.—A note presented to the French Academy. Between two cylindrical vertical armatures, a,

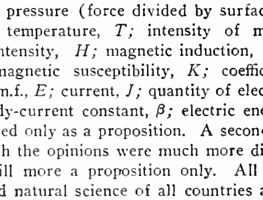

FIG. 3.—WIRELESS TELEGRAPH RECEIVER.

a needle is suspended by a wire; it carries at its ends two cylindrical parts, a', which are metallically connected, as shown in Fig. 3. The armatures, a, are connected by a coil of thick wire, S, with a convenient self-inductance. The one terminal of the apparatus is connected to earth, *T;* the other to the vertical wire, *A.* When electric waves touch the latter, an alternating potential difference is impressed upon the terminals of the apparatus, of a frequency equal to that of the wave. Under these conditions the needle turns around its point of suspension, *o*, so as to increase the capacity of the system. When the waves cease to arrive the needle returns to its position of equilibrium on account of the torsion of the wire. He made some experiments over a transmission distance of 10 meters, with a length of vertical wires 2 meters, spark length 0.25 mm., wave length 12 meters, number of sparks per second, 80. Under these conditions the permanent deviation observed is 80 mm.—*L'Ind. Elec.,* March 25.

New Books.

Die Herstellung der Akkumulatoren. Ein Leitfaden. Von F. Grunwald. Halle: Wilhelm Knapp. 158 pages, 91 illustrations. Price, 3 marks.

This is a small book of convenient size to be carried in the pocket, and has found many friends among accumulator engineers in Germany. It contains in very concise form almost everything that one should know in connection with storage battery engineering. It is, of course, more intended to be used by engineers who employ storage batteries than by those who build them. Nevertheless, the author has endeavored to be up-to-date even in those parts in which the theory and the manufacture of the storage battery are discussed. The American engineer may read with interest the German laws regulating the conditions of working in storage battery factories and the safety regulations of the German Institute of Electrical Engineers.

Les Chemins de Fer Electriques. By Henri Marechal. Paris: Ch. Beranger. 599 pages, 516 illustrations.

This book is, like the author's treatise on electric tramways, a general review of the whole subject under consideration. It appears to attempt a differentiation between street railways and other roads, especially such as would hitherto, under the older régimé, have been operated by steam. As a matter of fact, however, the treatment is rather more general and comprehensive, as one finds included such diverse topics as electric locomotives for mining purposes, and the moving sidewalk at the Paris Exposition and Chicago, as well as brief references to elevators and traveling stairs.

While one cannot speak of any special feature of novelty in Mr. Marechal's work, it has value, particularly as a résumé of the subject. Chapter 4, for instance, has quite a collection of third rails and shoes, in perspective and section, and illustrates the wide variety of practice in this country and abroad. Systems of train control are also summed up in an interesting manner. When it comes to motors, the author has not had an easy task in making a distinction between those for railways and those for trolley lines. Perhaps the broad, fundamental difference would consist in locomotives *per se* and in self-propelled cars carrying passengers; but even here the same motors can be used.

It seems to us that such a work as this should have given considerable space to the work at Zossen, bringing in the question of high speeds and of other contacts than the third rail. Zossen is referred to, it is true, but very briefly, and yet its lessons are uppermost to-day in the minds of engineers. We do not find much about interurban systems, nor anything about the recent single-phase work, although this is possibly too near at hand to get into the books. The volume would be greatly improved by a good index; in fact, it is a crime to issue such an excellent treatise without one.

Electricity and Matter. By Prof. J. J. Thomson. New York: Charles Scribner's Sons. 162 pages and 22 illustrations. Price, $1.25 net.

This very interesting and suggestive little book comprises Prof. Thomson's lectures under the Silliman foundation at Yale University, by which they are copyrighted as the first in the series constituting a memorial. The lectures were delivered in May, 1903, since when the views they embody have become well known in the domains of physics and electricity. The chapters follow apparently the lines of the lectures and deal with the representation of the electric field by lines of force; electrical and bound mass; effects due to the acceleration of Faraday "tubes"; the atomic structure of electricity; the constitution of the atom, and radioactivity and radioactive substances. Here we are, indeed, on the firing line of physical research. Perhaps after a reading of these lectures, the intelligent public may be willing to accept Prof. Thomson's terse statement that "We know, in fact, more about the 'electric fluid' than we know about such fluids as air or water." The chip which Prof. Thomson thus boldly puts on his shoulder may be as difficult to dislodge as the little chip of electricity, which he puts on the shoulder of his hydrogen atom. It is interesting, to say the least, that these lectures should have been delivered in New England, a region built up, one might say, by the negatively charged human corpuscles of the early migration, each puritan and pilgrim father bearing his eternal negative and protest against the constitution of things on the other side, where the great conservative majority of his race stayed. In the above statement, however, Prof. Thomson simply repeats what he said in the *Popular Science Monthly* in 1901, viz.: "The electric fluid is much more amenable to experiment than an ordinary gas, and the details of its structure are more easily determined."

The closing chapter on radioactivity is full of interest, though of course a great deal has happened in the year since it was given out. We note the reference to water from wells, which created a stir at the time and has been followed up with striking results, including "liquid sunshine." It is a great pity Prof. Thomson could not come over again and give a few more such lectures, embodying the latest theories as to rays and corpuscles.

The Truth About the Trusts. By John Moody. New York: Moody Publishing Co. 540 pages; charts and maps. $5 net.

It can safely be asserted that no economic subject occupies greater attention at the present time than the industrial consolidations or combinations known generally as the "trusts." These organizations have come to play such a prominent part in national life and national affairs that the whole social mechanism seems to have been thrown out of adjustment by their existence, and a large part of American legislation and conversation is taken up with discussion of them—their restriction, regulation, influence, future, remedies, justification, etc. At such a time, therefore, a book that will present the data as to the trusts is both timely and valuable, and Mr. Moody has done a public service in making this remarkable compilation of facts. Granted that some of the material is rather crudely massed or handled, it is there; and in view of the many difficulties surrounding the task, and the possibility of early improvement in later editions, Mr. Moody can congratulate himself on his work.

The trusts are classified in this volume and the first part is devoted to seven "greater industrial trusts" with a capitalization exceeding the vast sum of $2,660,000,000, which at current market quotations is perhaps worth about half that figure. These include the corporations associated with copper and steel. Then follow the "lesser industrial trusts," which include the General Electric Company, dubbed here "The Electric Supplies Trust," and the Westinghouse Companies. Next come the "greater franchise trusts," and here we strike telegraph and telephone companies, local lighting companies, street railway companies, etc. With this section goes a very interesting "family tree" chart showing the close relationship of the New York franchise corporations to the Standard Oil or Rockefeller group of financiers.

So far as we can determine, the data are set down carefully and accurately, so that a student can do a good deal of his own compiling and analyzing. Here and there are slips due to haste, possibly, or some unfamiliarity with the subject. For example, on page 373 it is set forth that the Bell telephone system has 1,500,000 exchanges, while the graphic chart facing page 376 compares 3,660,000 Bell instruments with 2,000,000 in the hands of the "independents." As a matter of fact, the Bell system had last year about 1,500 exchanges, 1,800 branch offices and 1,800,000 sets, or to be exact, some 1,300,000 stations. The error arises from the pernicious old Bell habit of rating the instruments separately, viz.: the transmitter as one and the receiver as one. Many people count each of these as a subscriber or station, as was done only this month by a well-known weekly electrical journal, which should certainly have known better.

After all is said and done, the perusal of such a book as this helps toward a calm survey of the field, and tends to strengthen the connection that when everything is said and done success in the biggest enterprise as in the smallest depends on a sound foundation, on able management, on wise capitalization and on public respect. Recent events have shown that the state can easily control its own creations, and that these, if bad in conception and worse in execution, soon go to pieces. Meantime, no one yet has been able to offset or gainsay the economic advantages of operation on a large scale.

World's Fair Electric Railway Tests.

As has previously been noted in these columns, an important work that will be done at the World's Fair is the testing of electric railway equipments. This work has been placed with a Railway Test Commission, which has appointed four engineering committees to report on the detail tests for different classes of service. Later a committee was appointed which will have direct charge of carrying on the work of the tests as outlined by these several committees. The chairman of the latter committee is Prof. W. E. Goldsborough and under his supervision the tests will be conducted by Prof. H. H. Norris, of Cornell University, who will be assisted by several electrical engineers not yet named and by ten students from the present engineering graduating class of Cornell; the latter have commenced a special study of test details preparatory to their work. The commission has also appointed an advisory committee to oversee the tests and represent the manufacturers, consisting of Mr. A. H. Armstrong, of the General Electric Company; Mr. Clarence Renshaw, of the Westinghouse Electric & Manufacturing Company, and Mr. Ward S. Arnold, of the Bullock-Allis Chalmers interests.

Twenty of the committees on details of tests have already reported. The committee on tests of heavy traction equipment, consisting of Messrs. F. J. Sprague, B. J. Arnold, W. J. Wilgus and F. R. Slater, present their outline under ten heads, as follows:

(1) Each party submitting apparatus for test shall furnish a complete written description thereof, setting forth clearly the special features of the design and calling attention to any points that are considered new. The description shall also explain the controlling mechanism, designating its applicability to direct or alternating current, with proposed working voltage, and if for alternating current, stating the frequency and phase desired for most successful operation.

(2) All tests shall be conducted upon the track designated by the Electric Traction Commission and conducted under actual operating conditions.

(3) No tests shall be made upon electric locomotives or other apparatus of less than 500 normal hp unless especially permitted by the commission. It is assumed that the term "Heavy Traction" applies to locomotives or motor cars of a total capacity rated on an hourly basis of 500 hp or more.

(4) The tests will be conducted with the locomotive or motor cars running light and also when pulling trains, with the purpose of studying the following features: (*a*) Motor capacity in various conditions of operation; (*b*) acceleration; (*c*) coasting; (*d*) braking; (*e*) heating. The following curves and diagrams shall be prepared: (*f*) Speed time curves; (*g*) distance time curves; (*h*) voltage and ampere time curves; (*i*) kilowatt input and distance curves; (*j*) draw-bar pull diagrams made when attached to a fixed anchor and also with dynamometer coupled between locomotive and trains operated under running conditions. If alternating-current motors are used the following additional curves shall be prepared: (*k*) Real kilowatt time curves; (*l*) apparent kilowatt time curves.

(5) The tests shall include the determination of heating and the distribution of same in the field, armature and commutator under various loads at different rates of speed. The heating of the bearings shall also receive consideration.

(6) The tests of the methods of control and comparison of hand and automatic acceleration shall be made as bearing upon the elements of (*a*) safety; (*b*) convenience; (*c*) economy; (*d*) smoothness of operation; (*e*) ability to group into two or more units.

(7) The tests of the method of control shall also be considered as bearing on: (*a*) Smoothness of acceleration; (*b*) variation of economical speeds; (*c*) reversibility; (*d*) action with one or more motors cut out; (*e*) relation of starting to running current under different rates of acceleration.

(8) The equipment will be considered as to: (*a*) General construction; (*b*) weight and distribution of same on drivers under static and hauling conditions; (*c*) relative weights of electrical and mechanical parts; (*d*) number and size of drivers; (*e*) acceleration of working parts; (*f*) influence on track.

(9) Tests will be made upon each locomotive or motor car submitted, to ascertain: (*a*) Watt-hours per ton-mile with locomotive running light at various speeds; (*b*) watt-hours per train ton-mile, exclusive of locomotive; (*c*) watt-hours per ton-mile with locomotive load and with train under various weights and acceleration.

(10) Methods and detail conditions for conducting the tests shall be agreed upon by those who have immediate charge of the tests before the commencement of the trials. These conditions shall be satisfactory to the representatives of those furnishing the apparatus. It is understood that all tests shall be made under similar conditions when possible. When these conditions are necessarily dissimilar due allowance shall be made in compiling the results, so as to place all apparatus upon the same plane of comparison.

The committee on tests to be conducted upon new electric railway systems at the St. Louis Exposition, consisting of Messrs. B. J. Arnold, Paul M. Lincoln and W. B. Potter, report as follows:

Each party furnishing apparatus to be tested shall submit a written or printed description setting forth clearly and fully the salient points in the system, and the principal advantages claimed for it. He will also completely describe the motors and controlling apparatus, stating whether the system is designed for direct current or alternating current, or both, and if for alternating current, whether for single-phase, multiphase, series, repulsion, inductive, synchronous, or other type of motor, and state in any case the most desirable voltage to use in the motor, and if alternating the preferred frequency.

In testing any new system we have assumed that the tests should be divided into two principal parts as follows: 1st. Motors, including car equipment. 2d. Line, including all sub-station apparatus and other translating devices interposed between the power house bus-bars, and the trolley wheel or contact shoe of the locomotive or car.

Schedule of motor tests to be made with apparatus running stationary upon testing blocks: (*a*) Test motors to determine efficiency, power factor (if alternating), torque, speed, horse-power output under various conditions as to voltage, frequency (if alternating) and current, to be met in the service for which the system tested is intended. (*b*) The one-hour rating of motors to be determined according to the standards outlined by the American Institute of Electrical Engineers. (*c*) Test motors under constant loads to determine rate of heating during continuous operation.

Schedule of tests to be made on equipment when operating upon experimental track: (*a*) Acceleration tests on single cars and multiple-equipped trains. (*b*) Braking tests of single cars and multiple-equipped trains. (*c*) Coasting tests of single cars and multiple-equipped trains. (*d*) Motor heating tests on single cars and multiple-equipped trains.

The following curves are to be prepared: (*e*) Speed time curves; (*f*) ampere time curves; (*g*) volt time curves; (*h*) real kilowatt time curves; (*i*) apparent kilowatt time curves (if alternating); (*j*) distance time curves; (*k*) tests and curves to determine car and train friction.

Schedule of tests to be made upon line and auxiliaries: Determine (*a*) Ohmic resistance; (*b*) inductive reactance; (*c*) power factor; (*d*) efficiency.

The determination of data of the copper and iron portions of line, separately and jointly, is to be made under the following conditions: 1st. When the electrical energy is delivered from the power house bus-bars to the working conductor without translating devices. 2d. When electrical energy is delivered from the power house bus-bars to the working conductor through supplemental transmission lines or translating devices. If supplementary transmission lines or devices are used in case No. 2 each element shall be tested separately as well as in conjunction with the line as a whole as outlined above.

Tests upon each system shall be made to determine the following: (*a*) Watt hours per ton-mile at car; (*b*) watt hours per ton-mile at sub-station bus-bars (in case sub-stations are used); (*c*) watt-hours per ton-mile at power house bus-bars.

All tests to be under like conditions, and when conditions are necessarily unlike, due allowance shall be made to reduce the apparatus tested to a fair basis for comparison.

The watt-hours per ton-mile, as stated above, to be determined from the summation of the specific tests hereinbefore outlined, and checked by integrating wattmeters placed on the power house bus-bars, sub-station bus-bars (if sub-stations are used), and the car.

100-Ton Double Trolley Alternating Current Crane.

By W. W. Briggs.

The Southern Pacific Company has recently completed at Los Angeles, Cal., the construction of one of the best-equipped and most modern railroad repair shops in the West. When the subject of

FIG. 1.—GENERAL VIEW OF CRANE.

crane equipment was under consideration by the officials of that company, the question as to whether the motors for operating cranes should be alternating or direct current was thoroughly canvassed.

Provided they could be operated successfully, it was desirable to use alternating current, for the following reasons:

First, on account of the fact that there was a large and reliable source of alternating current available at favorable rates, from the lines of the Pacific Light & Power Company, one of the long-distance power transmission companies of California. Second, the saving in wear and tear on motors, owing to the absence of commutators and brushes. Third, the increase in efficiency gained by elimination of transformers and rotary converters, or motor-generator sets for converting the alternating-current supply into direct current. Fourth, the considerable saving in first cost of converting apparatus.

A majority of the crane builders were opposed to the use of alternating motors for this service as they hesitated to take the responsibility of recommending an alternating-current equipment on a crane of this size, principally "because it had not been done before in this size equipment." Further, when the opinion of a number of Eastern railroad master mechanics was asked, the consensus of opinion was in favor of direct-current motors, mainly for the same reason advanced by the crane builders.

After carefully considering the matter, the officials of the Southern Pacific Company, with their characteristic courage and determination that everything in the way of new equipment should be of maximum efficiency, decided to "make history" with reference to this much mooted question, and take advantage of the many desirable features of alternating-current motors. Accordingly they placed their order for a crane equipment using that class of motors, which is one of the largest now in use.

The crane was built by the Niles-Bement-Pond Company and is of the double-trolley, double-girder class. The girders are double-webbed or box section form with end carriages of structural steel, each girder weighing 17,400 pounds. The crane span is 37 ft. 5 in., lift of main hook 16 ft. 6 in. Each main trolley or hoist has a capacity of 50 tons, one main trolley being equipped with an auxiliary hoist of 5-tons capacity.

Each main hoist is driven by a 50-hp (nominal) alternating-current crane type motor and is fitted with electric brakes. The main hoists are moved on the bridge by a 10-hp (nominal) motor. A motor of the same rating is also used on the auxiliary hoist. The bridge is driven by a 50-hp motor.

The operating speeds are for the main hoist, full load 10 ft. per minute, 20 ft. per minute light load; trolley, full load 80 ft. per minute, 100 ft. per minute light load; bridge, full load 175 ft. per minute, 225 ft. per minute light load.

The motors are three-phase, 440-volt, 50-cycle, Westinghouse variable-speed induction motors built with special reference to the duty required. Speed control of the motors is secured by using for each motor a three-phase Westinghouse crane type controller in connection with auto-transformers, but one set of two transformers being used for all the motors. The controllers are fitted with preventive resistances on contact arms which effectively prevent sparking at controller contacts. The use of auto-transformers allows of variable voltages being applied to the motors without the losses incident to rheostats.

The installation of this crane has been completed, and on test it has proven an unqualified success. Each main hoist has been tested with a load of 65 tons and handled that weight with ease and delicacy. The crane was run full speed down the shop, and when under full headway was reversed full speed in the opposite direction. This was accomplished without the slightest apparent straining or racking of gears, the action of the induction motors being much smoother than probably could have been secured with direct current.

The successful operation of this crane has afforded the management of the Southern Pacific Company much satisfaction and reflects credit on the company's engineers for having the courage of their convictions in making such a radical departure in shop practice. Doubtless the example will be followed by others and alternating-current motors for crane service will soon receive the recognition to which they are entitled.

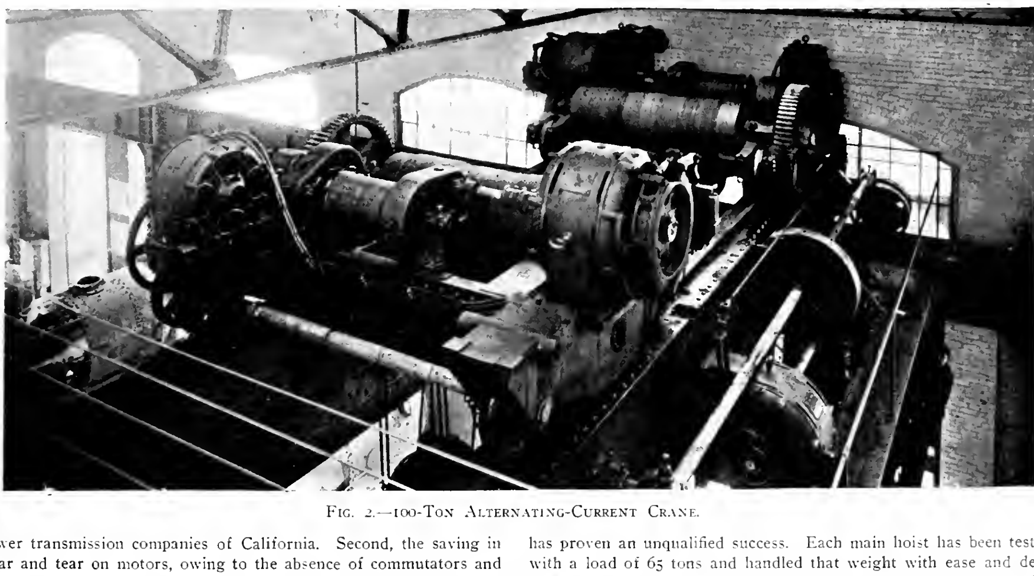

FIG. 2.—100-TON ALTERNATING-CURRENT CRANE.

New Westinghouse Railway Motor.

We illustrate herewith a new Westinghouse railway motor, known as No. 85, which is particularly adapted for suburban and interurban service, and comprises a number of features of advanced construction. The motor is rated at 75 hp nominal, and has a continuous service capacity of 60 amp. at 300 volts, or 55 amp. at 400 volts, these voltages being selected as representing a fair average of the voltage at the motor terminals under usual conditions. Conditions of service differ so largely, however, and so many elements enter into the problem of a given case that the nominal rating of a motor can only be regarded as a rough approximation; that the real criteria are the characteristic curves, which are here given in Fig. 5. In ordinary railway service the manufacturers recommend the motor as being able to carry safely any load within the range shown on the performance curves, provided the integrated heating effect does not

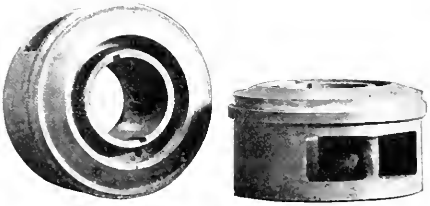

FIG. 1.—ARMATURE BEARINGS.

exceed that caused by the continuous application of either of these currents at the corresponding potential.

With a load of 60 amp. at 300 volts, or 55 amp. at 400 volts carried continuously during a shop test, the rise in temperature of the motor windings, as measured by thermometer, after ten or twelve hours, or after a constant temperature has been reached, will not exceed 75° C. With equivalent load under a moving car the temperature rise should not exceed 55° C. Heavier loads may be carried for shorter periods, as indicated by the time temperature curve. If, for example, the motor has been working at a load of 60 amp. at 300 volts, and has reached a temperature of 75° C., it may then carry a load of 72 amp. at 300 volts for one and one-half hours, with additional rise in temperature not exceeding 20° C. Speed, tractive effort, efficiency and power developed are also indicated for different gear ratios and under conditions ranging from currents of 30 to 240 amp. at the normal potential of 500 volts.

The frame of the motor is made of cast steel divided horizontally in two parts, forming a field which is wholly iron clad, and approx-

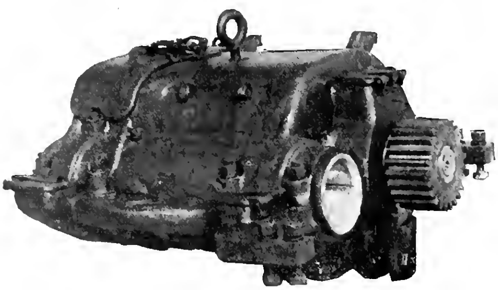

FIG. 2.—MOTOR AND PINION.

imately cylindrical in shape. The design is such that when mounted on the truck the holding bolts may be withdrawn and the upper field lifted off. To this end the suspension lugs and projection for the support of the gear case are cast with the lower field. A large opening with a spring-locked cover permits access to the commutator and brushes. Hand-holes are provided in convenient locations about the motor frame. The four pole pieces are built up of soft steel punchings riveted together between end plates of wrought iron and are held to the motor frame by bolts. The poles project radially inward at angles of 45° with the horizontal. The bolts holding the pole pieces in place do not penetrate the pole face, but terminate in heavy rivets inside the pole made for this purpose. A smooth and unbroken pole face is thus presented to the armature. The poles are made with projecting tips, which properly distribute the magnetic field, and also serve to retain the field coils, which are held firmly in place by steel spring washers. The coils are wound with asbestos-covered wire. They are heavily taped and are treated with specially prepared insulating compounds, which render them practically moisture-proof.

The armature core is formed of circular punchings of soft steel, built up upon a cast-iron spider. Ventilating spaces are provided in the core at right angles to and parallel with the shaft. The spider is pressed on and keyed to the shaft. The commutator also is

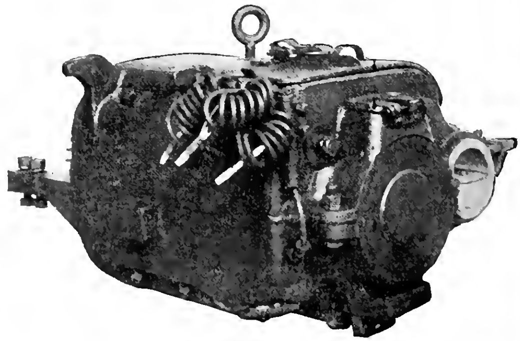

FIG. 3.—ANOTHER VIEW OF MOTOR.

mounted on the same spider, and the shaft can thus be taken out and renewed, should this be necessary, without disturbing any other part.

The armature is wound with machine-formed coils imbedded in rectangular open slots and held in place by band wires sunk in grooves. It is, therefore, wholly iron-clad, and the winding protected against mechanical injury. Canvas caps protect the winding at both ends, completely covering the parts of the windings outside of the armature core. The end plate at the pinion end is provided with a bell-shaped flange upon which the windings rest. This flange also holds the ends of the coils rigidly in place. The ends of the coils and the back of the commutator are thoroughly protected from carbon and copper dust. The complete armature is 15¾ in. in diameter. Wiper rings pressed upon the shaft outside the armature revolve in spaces in the motor frame inside the bearing boxes and prevent oil working its way along the shaft to commutator or winding. Oil thrown off by these rings is drained through suitable openings.

The commutator consists of 117 hard-drawn copper segments with short necks, separated by prepared mica sheets, built up upon a cast-iron bushing and clamped between two V-shaped surfaces, from which they are insulated by similarly shaped rings of moulded mica. The complete commutator measures 12 in. in diameter by 4¾ in. in width, and has a wearing depth of approximately 1 in. It is pressed on and keyed to the armature spider.

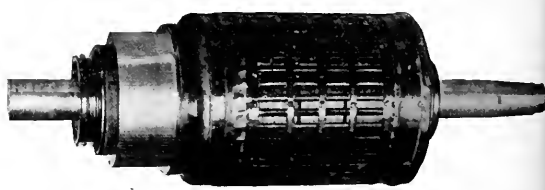

FIG. 4.—ARMATURE.

The brush holders are of the sliding shunt type, and are mounted on cast brass arms, which are secured to the motor frame by vulca-beston headed bolts. These arms admit of radial adjustment to compensate for wear of the commutator. The tension springs may be thrown back and fastened out of the way, facilitating the inspection of the brushes. Each arm carries two carbon brushes ½ in. by 2 in. section. The tension springs for each brush are independently adjusted. Flexible leads of rubber-insulated cable are brought out through bushings of semi-hard rubber set in the motor frame.

The motor is designed for either nose or Baldwin-Westinghouse suspension. Before leaving the works each motor is run under load and the insulation is submitted to an alternating potential of 3,000 volts. This final running test supplements a long series of tests and inspections of each and every part during construction.

The motor, complete with gear and gear case, weighs approximately 4,500 pounds. The motor alone, without gears and gear case, weighs approximately 4,000 pounds. The complete armature, with commutator and shaft, weighs approximately 995 pounds. The weight of a complete double equipment, including motor, controllers and the usual details, is approximately 10,780 pounds, and that of the corresponding four-motor equipment approximately 21,640 pounds.

The operating characteristics of this motor are clearly indicated

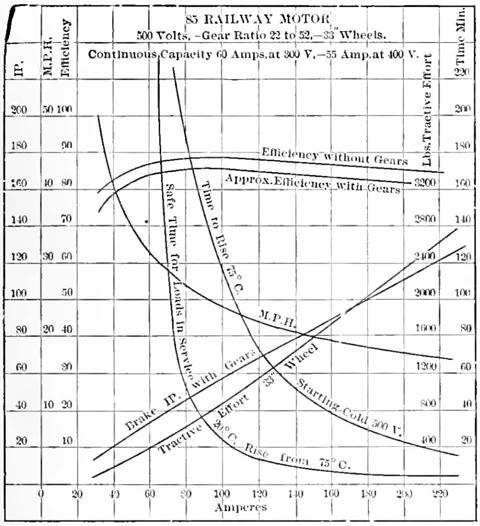

FIG. 5.—PERFORMANCE CURVES.

by the performance curves, one of which, for a gear ratio of 22 to 52, is shown in Fig. 5. A quadruple equipment is well adapted to the operation of a car of from 20 to 25 tons (without equipment or load) at a schedule speed of approximately 25 miles per hour, with stops at intervals of 1½ to 2 miles. With 36-in. wheels and gears of standard ratio, a maximum speed of 45 miles per hour may be maintained.

Equipment for Jersey City Printing Plant.

The Jersey City Printing Company is following close in the lead of other operators of large press plants in having extensive changes made in the power plant and transmission system. The entire machinery of the plant, including the high-duty presses and auxiliary machinery used for printing the New York Telephone Company's directories, will be operated by motors directly attached to the printing presses.

The motors will be 75 in number, ranging in capacity from ½ hp to 35 hp. They will be built by the Crocker-Wheeler Company.

Some novel features in the mechanical application of the motors will be introduced, particularly in the Cutler-Hammer controlling and starting devices, the question of manipulating the high-pressure current with absolute safety of fire risks receiving special attention. All the circuits are to be of specially high tension. The insulated wire will run in armored conduit and the starting boxes and auxiliary controllers will be steel-incased, affording the same kind of protection as the street car controller type of apparatus. The voltages used in the plant will be 500, 250 and 10, the low tensions acting principally for the purpose of operating solenoid controls for automatic stops, etc.

A new power plant will be installed of 200-kw capacity. There will be a 150-kw also a 50-kw Westinghouse generator, three-wire, 500-250-volt direct-current type. The engines will be of Harrisburg build of 225-hp and 75-hp capacity, respectively. Mr. Watler Kidde, 95-97 Liberty Street, New York, designed the equipment. This is but another instance of the manner in which the large new printing offices are adopting electrical equipment wholesale. The *New York Times* is a further case in point.

Fort Wayne Single-Phase Wattmeter.

The accompanying illustrations illustrate the integrating induction wattmeter for single-phase alternating-current circuits made by the Fort Wayne Electrical Works, and known as Type K. As indicated by the engraving, this wattmeter is very compact in form, requiring a space of only 6¾ x 8⅞ x 6¾ in. for installation. The cast aluminum case is put on directly from the front and requires but one screw, shown at the top, to securely fasten it. It is seated in a deep felt-lined groove in the frame, making a dust and insect-proof joint.

The series coils of the meter are clamped on brass spiders mounted on the back wall of the base and connected directly to binding posts above. The shunt armature coils are held by brass clamps mounted on the armature core, which is clamped to the back wall of the base. The adjustable starting device is mounted on a bracket on the lower part of the base, this bracket also carrying the permanent magnet, which is adjustable in position for varying the drag on the armature. The impedance coil in the shunt circuit is located in the base of the frame and is covered by a cap on the back of the meter fastened from the inside.

The rotating parts consist of a slender steel shaft having a shoulder to receive a stamped aluminum disc. This shaft is supported by a lower jewel bearing and guided by a top bearing stud. By the removal of the registering mechanism the rotating parts of the meter can be removed, thus exposing the interior of the instrument, as

FIG. 1.—WATTMETER.

FIG. 2.—ALL MOVING PARTS REMOVED.

shown in Fig. 2. The jewel bearing is mounted in a screw which is adjustable vertically; it rests on a coil spring within this screw, which is of such strength as to support the rotating parts flexibly, thereby preventing any wear on the jewel that might be caused by vibrations of shocks from the rotating parts. The jewel screw can be raised or lowered and mounted in position after the proper adjustment is made. A guide screw provides means for raising and supporting the shaft from the jewel when the meter is not in service. The top bearing for the shaft consists of a brass stud held by a set screw in the bracket which supports the registering mechanism. The shaft is accurately ground to a microscopic finish. While the motion of the integrating train of gears driven by a worm on the armature shaft is comparatively slow, to reduce friction to its lowest turns, both the gears and worms are cut as accurately as watch gears and then given a microscopic finish and inspection.

The permanent magnet is held in position on the front of the lower bracket by a brass clamp, and is adjustable vertically for varying the drag on the aluminum armature. The upright position of the magnet and its distance from the series coils prevents magnetic disturbance from any excessive current in the coil caused by short-circuit or sudden overload. In the manufacture of the permanent magnet, use is made of the most refined methods known to the art, these methods having been developed through years of experience and study.

To compensate for static friction an adjustable starting coil is connected in the shunt circuit of the meter, the coil being mounted on a small laminated iron core or arm. By a proper disposition of the end of this arm with relation to the core of the main shunt coil, the meter may be adjusted and set by screws *A*, *B* and *C* for starting with the smallest commercial load. Such adjustment is very sensitive and easily made without affecting any of the other adjustments.

A feature claimed for this type of wattmeter is its ability to accurately measure overloads, both inductive and non-inductive, of any character and to carry continuously and measure accurately such loads without injury. The meter is so constructed that no high temperatures are attained when operating under such conditions, thus obviating any damage to the installation or otherwise affecting the meter. All meters are constructed for use on either 60 or 133-cycle circuits, only a slight change that can be made in a moment's time being necessary to adapt the meter for use on either circuit. On the outside of the impedance coil in the base of the meter are the ends of two wires which, when soldered together at *D*, introduce suitable impedance in the shunt circuit to lag the meter for use on a 60-cycle circuit. For use on 125 to 140-cycle circuits these ends are separated to obtain the proper impedance for lagging with a high frequency.

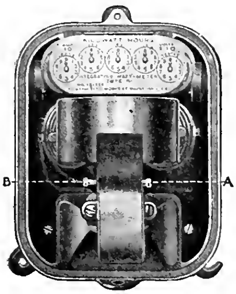

FIG. 3.—FRONT VIEW OF INTERIOR.

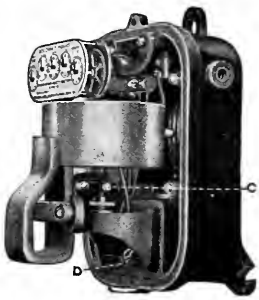

FIG. 4.—SIDE VIEW OF INTERIOR.

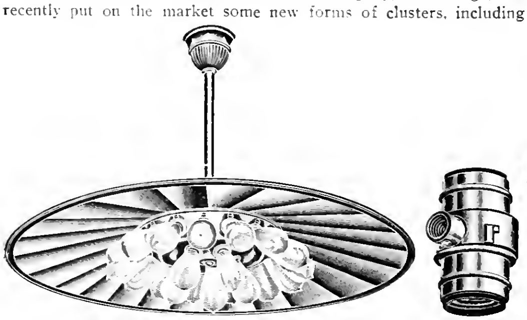
The meter is designed to measure accurately the energy of the circuit, regardless of variations found in wave forms in commercial service, and will not show appreciable error when subjected to most radical changes in wave form.

The counter of the meter is arranged to eliminate the constants or multipliers in obtaining actual energy ratings. In all sizes the dials are made direct-reading by using different combinations of gears in the counters. To prevent the introduction of these changes in the counter from producing excessive friction or drag and causing large errors on light loads, the values of the dials on large capacity meters are relatively increased. To further assist in rapid and accurate reading, the dial plate is made of a steel-finished porcelain, thus eliminating any reflection tending to obscure the dials.

Incandescent Lighting Clusters.

The Benjamin Electric Manufacturing Company, of Chicago, has recently put on the market some new forms of clusters, including



FIGS. 1 AND 2.—INCANDESCENT LIGHT CLUSTERS.

two forms of large-sized clusters, one of which is made in 8, 10 and 12 lights, and the other in from 15 to 20 lights. The latter form is illustrated herewith in connection with a large reflector, Fig. 1. The cut shows a 20-light cluster having 15 lights in the outer circle and 5 lights in the inner circle. These clusters are made up of sheet metal shell with suitable openings, in which are attached porcelain receptacles of special design. The receptacles have terminal plates inside of the shell and are easily connected as desired. By means of this receptacle, which is shown herewith (Fig. 2) it is possible to construct a large variety of forms and designs with any number of lights, such as hemispheres, etc.

A full line of the Benjamin products will be exhibited by the company at the St. Louis Exposition, Section 25, Electricity Building.

Curtis Turbines, etc. for Japan.

Contracts have been let for a number of Curtis turbines and other American electrical equipment for installation in Japanese electric light and mining plants.

The Yokohama Electric Light Company has ordered through the Japanese house of Mitsui & Co., 445-447 Broome Street, two Curtis turbines of 500-kw capacity each. The Tokio Electric Light Company has also contracted for a 500-kw turbine. These two companies are extending their plants. A contract for four 1,500-kw Curtis turbines is expected to be closed within the next week or two.

The power plant at the Kosaka Copper Mines is to be doubled in capacity. The existing equipment is of General Electric build. An additional 500-kw generator will be installed, together with a 165-kw motor-generator, three 200-kw transformers and a small direct-current moderate-speed generator as exciter. All the generating machinery will be built by the General Electric Company. The Kosaka plant is hydraulic and another Leffel water wheel will be installed with a capacity of 850 hp on a 104 head.

The Sumito Copper Mines will also be equipped with additional American machinery. Two 150-kw General Electric generators to be direct-connected to McIntosh-Seymour engines, have been requisitioned, also three General Electric transformers of 120-kw capacity each.

Reinsulation of Aerial Lines.

An interesting and ingenious device has been brought out recently for the reinsulation of aerial cables. It can be used for the application of water-proofing to all sizes of wires and cables for electric lighting, railways, power circuits, telephony, etc. It is shown in Fig. 1 and in use in Fig. 2. The device is composed of a cylindrical chamber arranged with a detachable section, whereby the apparatus may be fitted over the wire which is to be reinsulated. The insulating compound is introduced into the chamber from the top, and the

FIG. 1.—REINSULATOR.

FIG. 2.—REINSULATOR IN OPERATION.

device is held in an upright position on the wire by means of a weight. It is then drawn back and forth from pole to pole, giving the wire a uniform coat of insulation. This device has been brought out by the insulating varnish department of the Standard Varnish Works, 20 Broadway, New York City, and Mr. John C. Dolph has taken up its introduction in the east in connection with compounds manufactured for the insulation of aerial wires and cables.

Blue Printing With Enclosed Arc Lamps.

Within a comparatively recent period the work of blue printing in drafting offices has been revolutionized by the introduction of the

FIG. 1.—BLUE-PRINTING MACHINE.

electric light. Formerly it was necessary to depend upon sunlight, but at present most of the large drafting offices are fitted with an electrical outfit that enables blue prints to be made entirely inde-

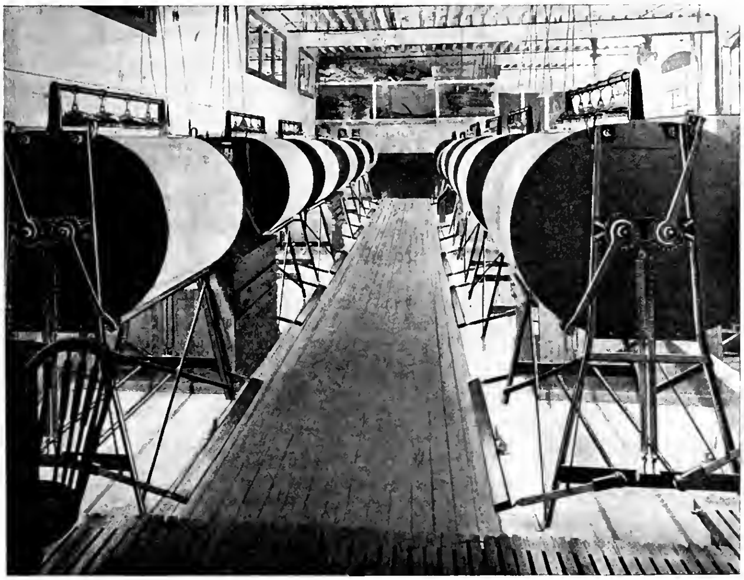


FIG. 2.—BLUE-PRINTING ROOM.

pendent of the state of the weather or hour of the day. Fig. 2 shows the interior of the General Electric Company's blue printing department, which is supplied with twelve four-arc lamp printing frames. During the month of January of the present year no less than 110,000 prints were made with this equipment without the aid of solar light. Ordinarily excellent prints are obtained in from one and a half to three minutes, though in exceptional cases as long as five minutes are required to obtain good results.

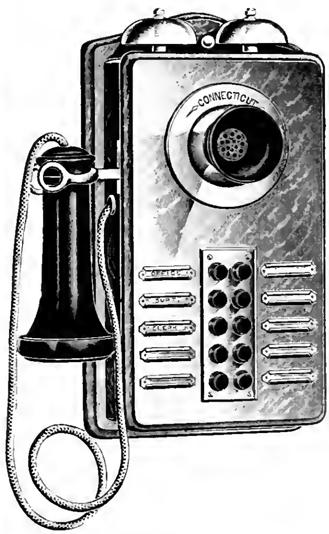
Fig. 1 shows one of the four-arc lamp outfits. The sides of the frames are made of curved plate glass against which the tracings and blue prints are placed, where they are held in position by canvas curtains operated by means of a foot lever. This arrangement holds the tracing firmly against the glass and insures a good contact between the tracing and the blue prints. The electric current is automatically turned on and off by means of a foot lever. The frame is constructed of angle iron and sheet steel, thus insuring lightness and at the same time strength and durability. The frame can easily be moved from one place to another to meet any emergency. By means of thin metal bands placed horizontally and vertically across the glass to hold the tracings, it is possible to make as many as thirty-two 8-in. x 10½-in. prints at one time.

Either direct or alternating current may be used. Four enclosed arc lamps with clear globes are employed as the source of light. While the blue-print apparatus was primarily built for use in the large blue-print department of the General Electric Company, the outfits are regularly sold.

Automatic Switchless Intercommunicating Telephone.

The Connecticut Telephone & Electric Company, of Meriden, Conn., has recently placed upon the market a new type of automatic switchless intercommunicating telephone. This instrument is a new departure, very simple in mechanical construction, and is covered by existing patents and other patents pending.

In designing this instrument the company have an ideal construction for cable connections, which are all made through the back of the instrument and on hard rubber. If any changes are desired it is not necessary to remove the telephone from the wall after it is once placed in position, as all parts are readily accessible, when the cover is removed. The company has done away with cables crossing hinge joints, crowding of parts, etc. The instrument is strictly automatic, and it is not necessary to remove the receiver before calling. With this instrument the call is accomplished and automatically made by pressing down the button of the station wanted. When the receiver is returned to the hook after using, all connections are automatically restored. The company has embodied in this instrument many valuable improvements such as are used in modern long-distance telephones.



INTERCOMMUNICATING TELEPHONE.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The stock market was dull with a declining tendency as a result of the firm stand assumed by the Hill-Morgan and Harriman interests in connection with the renewed litigation over the Northern Securities complication. Easy money and better reports of the condition of the iron trade created a demand for prime stocks at concessions, the market, however, being depressed in tone, the only strength being in specialties. The unfavorable April crop report and the continued bad weather in the Northwest and other sections also contributed to the general depression. Nor are railroad earnings considered to be satisfactory; and the backwardness of trade received some attention. United States Steel stocks were relatively firm as a result of the continued demand for iron and steel. The curb market was irregular with a smaller volume of business. Electric and traction securities do not show any activity of note, trading in all, excepting Brooklyn Rapid Transit being light. Of this latter stock, 135,800 shares changed hands at prices ranging from 45⅝ to 48⅜, the closing price being 46¼, a net gain of ⅞ point. Metropolitan Street Railway lost 3¼ points net on the week's trading, the range of prices being 113 to 117¼. The closing quotation was 113¾. General Electric was firm, closing at 164½, which was ½ below the highest figure of the week, the lowest being 163¾. The net result was a gain of ⅞. Westinghouse lost 1½ points net, closing at 161. Western Union closed at 88⅞, which is ⅛ less than the last previous quotation. American Telephone & Telegraph closed at 126, this being the ruling figure throughout the week, and an advance of 3 points. American Telegraph & Cable closed at 86¾, a net gain of 2 points. Following are the closing quotations of April 19:

*Asked

CABLE REAL ESTATE PURCHASE.—Ex-Congressman Jefferson M. Levy has sold out his interest in the Commercial Cable Building Company, New York City, to Clarence H. Mackay, leaving Mr. Mackay practically in sole control. The company owns the Commercial Cable Building at 20 Broad Street, running through to New Street, adjoining the Stock Exchange. Just what was the extent of Mr. Levy's ownership in the property is not known, but he is generally understood to have held about a one-half interest, having been the former owner of the site upon which the building was erected. The structure is twenty stories in height and covers a plot of about three city lots, although the company's holdings were increased two years ago by the purchase of adjoining property on New Street and Exchange Place. The site of the present building was transferred to the Commercial Cable Building Company on August 22, 1895, for an expressed consideration of $1,126,300. The value of the property to-day, ground and building, is believed to be in the neighborhood of $3,000,000. It is assessed for taxation this year at $1,850,000. Through the purchase by the Commercial Cable Building Company of the diminutive lot at the northeast corner of Exchange Place and New Street, owned by William F. Havemeyer, what had promised to be a long-drawn-out real estate war at that point bids fair to be ended. Mr. Havemeyer's parcel measures 34.5 by 26.10 ft. and is now covered by a little old three-story building. The Commercial Cable Company is said to propose an addition on it.

GENERAL ELECTRIC BUSINESS.—The *Wall Street Journal* has the following: "General Electric orders for electric apparatus have fallen off the past six months by between 5 and 10 per cent. Factories are working in many departments overtime on old orders, but new orders not forthcoming for electric construction in volume equal to a year ago. It is understood that General Electric the past year has done about $36,000,000 of gross, of which it is said that $12,000,000 has been wire, repairs and small material. It is not expected that the business of the present year will equal that of the year just ended. The General Electric Company is in strong financial position and never again expects to have to wrestle with debts whatever may be the size of any industrial depression. This is why it will sell stock even to take care of such a small matter as the $3,000,000 of debt inherited from the Stanley Electric Company. The General Electric Company could throw away all its three great plants at Schenectady, N. Y., Lynn, Mass., and Harrison, N. J., and pay $100 per share to its stockholders from its net treasury assets."

ALLIS-CHALMERS POLICY.—The better to put itself in position to make adequately the changes in its equipment for electrical and turbine manufacturing, etc., the Allis-Chalmers Company has passed the quarterly dividend on its preferred stock. The company is understood to have net working capital of considerably over $7,000,000, but proposes to strengthen its position and resources in every way. The Allis-Chalmers Company has $16,000,000 of 7 per cent. cumulative preferred stock and $20,000,000 common stock. It has no funded debt. No dividends have been paid on the common stock. The preferred dividend has been paid quarterly since the formation of the company, three years ago. In the first year's operation the company reported net profits of $1,442,259. Last year it reported $1,653,576. In the first year its balance sheet showed cash on hand, $4,514,167; in the second year, $1,628,009. The latest sales of the preferred have been around 43 and of the common at 7⅞. The balance sheet of April 30, 1903, showed also net current assets of $7,871,342.

INDIANA UNION TRACTION.—Indiana Union Traction Company reports results for the calendar year 1903 as follows:

Gross earnings	$1,118,951
Operating expenses	620,136
Total net receipts	$498,815
Fixed charges, including interest, taxes and licenses, and dividends on preferred stock of Union Traction Company of Indiana	358,511
Net income for the year, applicable to rental payments	$240,304

DIXON CRUCIBLE COMPANY.—The Joseph Dixon Crucible Company, of Jersey City, held its annual meeting April 18. These directors were elected: E. F. C. Young, John A. Walker, George T. Smith, Edward L. Young, William Murray, Joseph D. Bedle and George C. Long. The directors subsequently elected Edward L. Young president, John D. Walker vice-president and George C. Long secretary and treasurer.

MARCONI COMPANY.—At a meeting of the Marconi Wireless Telegraph Company, held in Jersey City on April 18, James W. Pike, J. P. Cotton and G. Marconi were elected directors to serve terms of five years, and H. H. McClure to serve until 1907. One of the directors outlined the work accomplished and the rapid strides with which the work of wireless telegraphy is being carried to a successful issue.

DIVIDENDS.—The Chicago Edison Company's directors have declared the regular quarterly dividend of 2 per cent., payable May 2. The National Carbon regular quarterly 1¾ per cent. preferred dividend is payable May 14. The directors of the American Gramophone Company have declared the regular 1¾ per cent. preferred quarterly dividend, payable May 15, to stockholders of record May 2.

W. U. BONDS.—The governing committee of the New York Stock Exchange has listed Western Union Telegraph Company $1,000,000 additional 4½ per cent. funding and real estate mortgage fifty-year coupon bonds, making the total amount listed to date $17,000,000.

Commercial Intelligence.

THE WEEK IN TRADE.—Reports of trade are not as satisfactory as they should be for this season, the chief reason being the unseasonably cool weather, which has a retarding effect along all lines. Business, as a result, was irregular, but the feeling is hopeful, the advent of warmer weather being the only factor lacking to instill new life. Foreign trade returns were more favorable to manufacturing than to agricultural interests. The industrial situation is not entirely favorable. The cotton goods industry is steadily curtailing production, but there is increased production, consumption and demand from various sources for iron and steel, coal, coke and lumber. Other industries are lagging. Notwithstanding the disappointing condition of spring trade in general, several markets report good orders for future delivery. Collections are not improved. Trade on the Pacific Coast is affected by backward weather, and in San Francisco labor conditions are very unsatisfactory. Iron was quieter. Finished products are in good demand, but manufacturers are buying merely to fill requirements. Some heavy transactions in cars are expected, there being a call for nearly 10,000 of them by several roads. The copper market, while firm, remains practically unchanged as to prices, Lake being quoted at 13⅝ to 13⅜c.; electrolytic, 13⅛ to 13¼c., and casting stock 12⅞ to 13⅛c. Transactions were on a limited scale as far as home consumers are concerned. The business failures for the week ending April 14, according to *Bradstreet's*, numbered 198, against 201 the week previous and 160 the corresponding week last year.

SOME CROCKER-WHEELER ORDERS.—The Crocker-Wheeler Company, through its New York office, under the management of F. B. De Gress, has secured a contract for a 100-kw engine type generator, to be direct-connected to a Ball & Wood engine for the Clear Creek Mining Company, Arbacoochee, Ala. The machinery will be used for general power purposes. The C. Martens Company, which operates a large bakery in Jersey City, has ordered four motors ranging from 3 hp to 15 hp. The Solvay Process Company, Syracuse, N. Y., has requisitioned for eight 12-hp motors for driving cranes. The Ansonia (Conn.) O. & C. Company has ordered a 50-kw belted generator for installation in its corset fittings factory. The New England Engineering Company, of New Haven, Conn., has ordered for the fifth time a number of small motors, which are to be used for ventilating apparatus in Yale University. The Eolian Company has called for three motors ranging up to 10 hp for its plant at 157 East Thirty-second Street. The Belvedere-Stratford Hotel, at Philadelphia, is to be installed with two small motor dynamos for the bell service; and C. S. Robinson & Co., of Princeton, N. J., have ordered some motors for their printing plant. Mr. De Gress reports that the amount of business handled through the New York offices this year has been on a par with that secured up to a similar period in 1903, large as that was.

STILWELL-BIERCE & SMITH-VAILE COMPANY.—The Stilwell-Bierce & Smith-Vaile Company, of Dayton, Ohio, has taken a lease of the extensive ground floor and basement at 93 Liberty Street, now being vacated by Stanley & Patterson, and will take possession about May 1. A very large stock of standard size pumping machinery—power, steam and marine—also Victor turbines, air compressors, feed water heaters and other specialties, will be carried. A full line of pumps and spare parts will also be on hand. The present New York offices of the company, in the Washington Life Building, will be removed to the new premises. The local sales organization of the company will be considerably strengthened. Six new men are now being engaged. Each machinery department will be under separate supervision and machinists will be on hand to erect and overhaul machinery. The management of the New York end of the company's business will, as heretofore, be in charge of G. W. Neff, the Eastern manager.

WESTINGHOUSE EQUIPMENT FOR CERRO DE PASCO MINES.—The Cerro de Pasco Mining Company, in which J. B. Haggin is the leading spirit, and of which Frank Klepetko, Battery Park Building, New York, is the consulting engineer, has awarded the contract to the Westinghouse Electric & Manufacturing Company for the electrical equipment to be installed at its huge copper smelter, etc., now under construction at Cerro de Pasco, Peru. The generating equipment will be of 350-kw capacity—one unit. This machine will be direct-connected to a cross-compound engine to be built by the Nordberg Manufacturing Company, of Milwaukee, Wis. Fourteen Westinghouse motors varying in capacity from 10 hp to 100 hp will be used for driving machinery in the foundry, sampling mill and machine shops.

150,000 LIGHTS FOR CONEY ISLAND.—The Wonderland Company has organized recently under the laws of the State of New York with a capital of $1,200,000, to operate a huge amusement resort entitled "Dreamland," in Coney Island, in which electricity will play a most important part. There will be upwards of 150,000 lights, the ballroom alone using 15,000. Ex-State Senator Reynolds is president of the company. Others largely interested are P. B. Purdy, J. H. Wythe, W. G. Groves and George E. Hall. The chief engineer of the company is C. C. Harley, an old Brooklyn Edison man. Power will be furnished by the Brooklyn Edison Company. Stanley & Patterson, 93 Liberty Street, have secured a contract reported to be valued at more than $50,000, for furnishing various supplies, etc.

EQUIPMENT FOR NEW BABBITT SOAP FACTORY.—B. T. Babbitt, the soap manufacturer, of 64-84 Washington Street, New York, is to construct a large plant at Granton, N. J., which will be electrically operated throughout. Howard R. Barton has been retained as consulting electrical engineer in the matter. He is now engaged in drawing up the plans, etc., and contracts for the necessary equipment are expected to be let inside of 30 days. The capacity of the plant will be about 500 hp. There will be two generating units of 150-kw capacity each. Fully fifty motors will be employed ranging in capacity from 1 hp to 20 hp. They will be operated mostly in groups.

THE ALLIS-CHALMERS COMPANY has lately sold to the Interborough Rapid Transit Company a surface condensing outfit to be used in connection with a 5,500-kw steam turbine, which is to be installed at the Manhattan power station, Seventy-fourth Street and East River, New York. This surface condenser has been especially designed for use with steam turbines to give the high vacuum which is required for this class of work, and will be built at the Allis-Chalmers works at Scranton, at which place a condensing machinery department has been established, and where the company intends to build condensers to meet every condition.

ELECTRIC CRANES FOR PERU COPPER PLANT.—The Alliance (Ohio) Machine Company has been allotted an interesting contract for electric cranes to be installed in the converter plant being built by the Cerro de Pasco Mining Company, Peru, for which Frank Klepetko is consulting engineer. There will be a 40-ton alternating-current crane fitted with two auxiliary hoists of 15-tons capacity each. The motors will be of Westinghouse type F build. They will be of 75-hp, 15-hp and 10-hp capacity. A 10-ton crane with two auxiliary hoists to be operated by Westinghouse motors—three of 20 hp each, has also been ordered.

EQUIPMENT FOR DRESSED BEEF PLANT.—The United Dressed Beef Company, First Avenue and Forty-third Street, New York, let a contract recently for the complete electrical equipment of its plant. The capacity will be 300 hp. There will be a 200-kw engine type generator of Crocker-Wheeler build direct-connected to a Fitchburg engine. The motor equipment will consist of eleven machines aggregating 170 hp and varying in capacity from 5 hp to 35 hp. The plant is to be installed under the supervision of A. G. Koenig, chief engineer of the United Company.

SHAW ELECTRIC CRANE ORDERS.—The Shaw Electric Crane Company, of Muskegon, Mich., has secured a substantial contract for cranes to be installed in the new locomotive shops at Spencer, N. C., of the Southern Railway. The contract calls for two 60-ton cranes and one each of 10-tons and 5-tons capacity. The 60-ton cranes will have 10-ton auxiliary hoists. The Indianapolis Light & Power Company has ordered a 50-ton crane with an auxiliary hoist of 10-tons capacity for installation in its new power station at Indianapolis.

LIGHTING EQUIPMENT FOR HALL OF RECORDS.—A 450-kw lighting equipment is to be installed in the new Hall of Records. The C. L. Eidlitz Company, 1168 Broadway, secured the contract. There will be two 150-kw and one 100-kw Crocker-Wheeler generators, also a 50-kw machine of same build. The engines for the larger generators will be Brown Corliss, while a Watertown engine will drive the 50-kw machine.

1,800-KW PLANT FOR NEW WANAMAKER STORE.—An 1,800-kw electric generating plant is to be installed in the new Wanamaker store to be constructed at Eighth and Ninth Streets and Broadway, by the Thompson-Starrett Company, 51 Wall Street. The contracts for the electrical equipment, consisting of six units of 300-kw capacity each, will be sub-let by Mr. Babbitt, the electrical engineer of the company.

TELEPHONE SUPPLY MANUFACTURING.—Various rumors are floating about in Chicago regarding the formation of an independent telephone manufacturing company to be controlled on a co-operative basis by independent telephone exchange companies. Nothing definite seems to have materialized. The name of Mr. James E. Keelyn has been mentioned in connection with the enterprise.

GOUBERT HEATERS FOR JAPAN.—The Goubert Manufacturing Company, Singer Building, New York, has a number of orders in hand for its specialties to be installed in Japanese electric plants. The Hanshin Electric Railway Company has ordered Goubert heating apparatus and one of the largest copper mines will also have Goubert heaters in its electric power plant.

SHELLAC is advancing again in price and is quoted now at 51 cents a pound. Stock are light, due, it is said, to a drought in India, from which it will take a long time to recover.

POLICE TELEGRAPH SYSTEM WANTED.—The city of Johnstown, Pa., is in the market for a police telegraph system and correspondence is solicited.

General News.

THE TELEPHONE.

CAMDEN, ARK.—The Ouachita Telephone Company of this city has been incorporated with a capital stock of $25,000, of which $10,000 has been subscribed. M. A. Joy is president; H. P. Snead, vice-president, and W. P. Ritchie, secretary and treasurer.

WATERBURY, CONN.—The Southern New England Telephone Company is planning to install a complete system of underground subway for its main lines in this city.

COEUR D'ALENE, IDA.—The Rocky Mountain Bell Telephone Company will extend its system within a few months in all directions from this point throughout the county.

CARTHAGE, ILL.—The Mississippi Valley Telephone Company has been formed here.

HARDIN, ILL.—The Farmers' Telephone Company will extend its line from Hardin southward to Meppin.

ARCOLA, ILL.—The Arcola Grain, Coal & Telephone Company has increased its capital stock from $5000 to $8000.

TREMONT, ILL.—The Tremont Independent Telephone Exchange has incorporated with a capital stock of $20,000. Mr. A. J. Davis is president.

UPPER ALTON, ILL.—A farmers' mutual telephone company has been organized east of this place by 35 farmers. They have decided to apply for a franchise to install a private telephone system in Upper Alton.

PEORIA, ILL.—Telephone and telegraph communication between here and Tazewell County points was entirely shut off by the fall of part of a bridge over the Illinois River at this city on April 4, caused by the undermining of two piers by the floods.

CHICAGO, ILL.—Miss Mary Schultz, who was an operator for the Chicago Telephone Company, was given a verdict of $15,000 against the company for an accident while employed at the switchboard, which, it is alleged, caused deafness in her left ear. It is said that she received an electric shock from the receiver.

MARION, IND.—The Roann Telephone Company is making preparations to extend and enlarge its plant.

INDIANAPOLIS, IND.—The Waupecong Home Telephone Company, of Waupecong, Miami County, has been incorporated. M. D. Hensler heads the board of directors.

GREENFIELD, IND.—The Cleveland Telephone Company, of Hancock County, has been incorporated. The incorporators are: E. H. Thomas, I. L. Sample, E. L. Furry and others.

INDIANAPOLIS, IND.—The city council at a special meeting passed an ordinance permitting the New Telephone Company to transfer its franchise and holdings to the Indianapolis Telephone Company.

WABASH, IND.—The city council has granted a franchise to the Central Union Telephone Company. The company has been doing buisness without a franchise for more than a year, during which time the council and company have been wrangling over the matter.

SUMMITVILLE, IND.—The Delaware and Madison County Telephone Company has begun the work of changing instruments and installing its switchboard at Summitville to replace the one formerly operated by the Central Union Company, and which was owned by R. M. Inglis. The Central Union will now operate only a toll station line.

GREENFIELD, IND.—The Blue River Telephone Company, of Hancock County, has increased its capital. The company was organized a year ago to furnish the farmers of Blue River township with reliable telephone service. The demands for telephones and the necessity for extending the 'lines has been so steady that an increase of capital was necessary to provide a new switchboard and other material. The improvements will be made at once.

EVANSVILLE, IND.—A permanent injunction against the Municipal Telephone Company, of Evansville, preventing it from doing business under the franchise granted some time ago by the city council, was issued April 8 by Special Judge W. D. Robinson, of the Indiana Appellate Court. This action creates a peculiar situation here. The Cumberland Company has been declared franchiseless. The city is now in a position to obtain the best advantage in the matter of granting a franchise.

RUSHVILLE, IND.—The annual meeting of the stockholders of the Rushville Co-operative Telephone Company was held last week. The secretary-treasurer's report showed the receipts for the year to be $15,404.19. Rentals for stockholders for residences were raised from 75 cents to $1, and for business houses from $1.25 to $1.50. H. E. Barrett, W. D. Root, B. L. McFarlan and T. M. Green were elected directors.

POCAHONTAS, IA.—The Pomeroy-Palmer Telephone Company has been formed here to build a rural line.

STUART, IA.—The Lincoln & Stuart Telephone Company will build an exchange here.

TAMA, IA.—The Tama Telephone Company has been incorporated with a capital stock of $150,000.

STORY CITY, IA.—The Gilbert & Story City Telephone Company has been formed to build a rural line.

DUNCOMBE, IA.—The Duncombe Telephone Company has applied for a franchise to install an exchange here.

DES MOINES, IA.—The Mutual Telephone Company will remodel and reconstruct its exchange and install entirely new equipment at a cost of $250,000. A new switchboard, having a capacity of 10,000 lines, is included in the new plans. It is stated that Stromberg-Carlson apparatus will be used.

SEMIWAY, KY.—The Cumberland Telephone Company is building a line from Rumsey to this place.

MIO, MICH.—Mio Telephone Company has been incorporated with a capital stock of $2000.

DETROIT, MICH.—It was reported recently that the People's Telephone Company had sold its Detroit property to the Michigan Telephone Company for $175,000. This report, however, is denied by Mr. J. B. Corliss, who has the disposal of the People's Telephone Company property.

HANSKA, MINN.—The Hanska Rural Telephone Company has been formed here.

LAKE CITY, MINN.—The Dwelle Telephone Company will extend its lines this year.

WINONA, MINN.—The Winona Telephone Company will build several branch lines this spring.

OWATONNA, MINN.—The Northwestern Telephone Exchange Company will rebuild its local exchange.

AITKEN, MINN.—The Aitken & Grand Rapids Telephone Company has been organized here and will soon build a line.

COTTONWOOD, MINN.—The Home Telephone Company has been incorporated with a capital stock of $10,000. The directors are: L. S. Reishus, Chas. Catlin and others.

MINNEAPOLIS, MINN.—The Northwestern Telephone Exchange will make extensive improvements to its system in the twin cities, extending the subway system and installing considerable cable.

RENVILLE, MINN.—The Renville Rural Telephone Company has been incorporated with a capital stock of $20,000 and will connect a number of towns under 2000 inhabitants by means of rural telephone lines. The incorporators are: A. E. Carver, A. E. Rieke, S. W. Smith, Paul Albrecht and C. W. Parsons, of Fairfax, and O. W. Harris and R. E. O'Keefe, of Franklin.

PELICAN RAPIDS, MINN.—The Pelican Telephone Company has been incorporated with a capital of $25,000, and has purchased the rural lines of the Fergus Telephone Company in this vicinity. The officers are: J. P. Wallace, president; C. M. Carr, vice-president; N. P. Moen, secretary; C. L. Ward, treasurer; C. D. Haugen, Knuts Steenerson and O. J. Morrison, directors.

PARIS, MO.—The Mutual Telephone Company is building a line from this place to Long Branch.

MEXICO, MO.—The telephone managers in Audrain County are making an effort to form an independent union of all the smaller companies in this section. A telephone franchise in this city will be applied for.

ST. LOUIS, MO.—Mr. L. W. Stanton, the consulting telephone engineer of Cleveland, Ohio, is supervising the installation of an all-cable telephone plant of between two and three hundred telephones, for the Controller Company of America, on the World's Fair Grounds, St. Louis. All the telephones used will be of the measured service type, manufactured by the Controller Company of America.

ALEXANDRIA, NEB.—The Farmers' Telephone Company has been incorporated with a capital stock of $5000.

ELBA, NEB.—The Howard County Telephone Company has been incorporated with a capital stock of $25,000.

PASSAIC, N. J.—The New York Automatic Telephone Company has been incorporated here with a capital stock of $50,000. The incorporators are: Charles R. Newman, George Roegnes and A. C. Gilgen.

MIDDLETOWN, N. Y.—The Scotchtown Telephone Company has been incorporated with a capital stock of $2000. The directors are Herbert Mills, M. H. Santee and others.

ALBANY, N. Y.—The Ulysses Co-operative Telephone Company, of Jacksonville, N. Y., has been incorporated with a capital stock of $7200. The directors are: S. W. Meckell, F. A. Miller and others.

HAMLIN, N. Y.—The Hamlin Telephone Company has been organized by local business men to build a line from Hamlin to Morton. The officers of the company are: President, D. R. Singleton; vice-president, Christopher Rath; secretary, H. F. Newman; treasurer, Charles Baase.

SOMERVILLE, OHIO.—The Hamilton Home 'Phone Company has secured a franchise from the village council.

COLUMBUS, OHIO.—The Albany & Vails Mills Telephone Company has reduced its capital stock from $10,000 to $1000.

FULTON, OHIO.—The Fulton Telephone Company has been incorporated with a capital stock of $5000 by E. E. Jackson and Chas. Feldon.

ENGLEWOOD, OHIO.—The West Milton Home Telephone Company will install new exchanges at Laura and Englewood and make other improvements.

LAMARTIN, OHIO.—The Dining Fork Telephone Company has been incorporated with a capital stock of $10,000. The directors are: E. H. Kennedy, J. Harrison and others.

TROTWOOD, OHIO.—The Trotwood Home Telephone Company has been incorporated with a capital stock of $10,000. The directors are: S. A. Blessing, W. L. Bosler and others.

MANCHESTER, OHIO.—The Brown Telephone Company has been incorporated with a capital stock of $20,000 by O. E. Bare and others. The lines of this company will connect several towns in this vicinity.

WILLAMETTE FALLS, ORE.—The W. W. Telephone Company has been incorporated with a capital stock of $10,000 by Guy Cross, C. G. Huntlet, G. H. Rogers and C. Baker. It is proposed to build a line from Willamette to Stafford.

GRIP, PA.—The Farmers' Union Telephone Company has been incorporated with a capital stock of $5000.

SCRANTON, PA.—The Pennsylvania Telephone Company has refused to furnish the fire alarm service after July 1. The city may have to issue $50,000 in bonds to intsall a system of its own.

BUFFALO, GAP, S. D.—The Cheyenne River Telephone Company has been incorporated with a capital stock of $10,000.

ABERDEEN, S. D.—The Dakota Central Telephone Company will expend a large amount of money in extensions and improvements this summer.

BROWNSVILLE, TEX.—W. H. Johnson and Mrs. J. M. Ellis contemplate establishing a local telephone exchange here. They will also build long distance telephone lines.

SAN ANTONIO, TEX.—The San Antonio Telephone Company is preparing to make improvements to its local system here to the amount of $100,000. D. A. Walker, of Columbus, Ohio, is president of the company.

HOUSTON, TEX.—The switchboard of the Southwestern Telegraph and Telephone Company's exchange in this city was damaged by fire April 2. The fire started either by lightning or a cross with an electric light wire. Four thousand telephones were affected.

SALT LAKE, UTAH.—The Southern Utah Telephone Company has been incorporated with a capital stock of $5000. R. C. Lund and E. H. Snow are among the directors.

SUSSEX, VA.—The Sussex and Southside Telephone and Telegraph Company has been incorporated with a capital stock of $5000.

CHETEK, WIS.—The Dunn County Telephone Company will establish a local exchange here.

GREEN BAY, WIS.—The Wisconsin Telephone Company will install an underground system here.

CADIZ, WIS.—The Cadiz Central Telephone Company has been incorporated with E. L. Divan as president.

BLACK RIVER FALLS. WIS.—The Central Wisconsin Telephone Company has increased its capital stock from $5000 to $50,000.

IOLA, WIS.—The Iola Telephone Company has been incorporated with a capital stock of $5000. The directors are: N. H. Johnson, F. W. Black and others.

ROBERTS, WIS.—The Roberts Telephone Company has been incorporated with a capital stock of $5000. The directors are: G. W. Turner, A. J. Walker and others.

MONDOVI, WIS.—The Mondovi Telephone Company has been incorporated with a capital stock of $24,000. The directors are: B. S. Lockwood, S. H. Hubbard and others.

VANCOUVER, B. C.—The International Telephone Company has completed arrangements whereby Vancouver and other places on Vancouver Island will be placed in telephonic connection with points on the main land as far south as Portland, Ore. The company is an amalgamation of the long distance telephone companies operating in British Columbia and is about to traverse the American islands in the Gulf of Georgia at the mouth of Puget Sound. The new company is capitalized at over $150,000.

ALBUQUERQUE, N. M.—It is reported that the Colorado Telephone Company, with headquarters at Denver, Col., will extend its lines to this place.

ELECTRIC LIGHT AND POWER.

JACKSON, ALA.—B. H. Warren is interested in an electric light plant for Jackson.

MORRISVILLE, ALA.—Louis J. Morris, of the Morris Mfg. Company, at Morrisville, it is stated, has signed a contract with the Talladega Light and Power Company for the construction of a dam at Choccolocco Creek to cost $25,000. The dam will be used to generate power for an electric plant.

BERKELEY, CAL.—The Berkeley Electric Co. has secured the contract for lighting the city for 2 years beginning April 1 for 160 lamps at $6 each.

VICTOR, COL.—Citizens are considering the building of a co-operative electric light plant. They are dissatisfied with the rates charged by the existing two companies.

WOODBURY, CONN.—It is proposed to establish an electric light plant here. E. S. Boyd can give information.

DOVER, DEL.—The Water and Light Committee of the town council has recommended that $8,500 be expended for improvements to the water and lighting plant.

JACKSONVILLE, FLA.—A 500-kw generator is wanted for the city electric light plant.

GREENSBORO, GA.—The council has granted T. B. Rice, of Greensboro, and R. L. West, of Atlanta, a franchise for an electric light plant.

COLUMBUS, GA.—The council has accepted the proposition of the Columbus Railway Company to furnish street lighting for 1905 at $60 per arc light per year.

BOISE, IDAHO.—The Idaho Brewing Company has installed electric power apparatus for the operation of its plant.

OTTAWA, ILL.—It will cost $8,000 to install an electric light plant in Ottawa according to estimates.

RIDGEFARM, ILL.—A new company has been organized by C. O. Linn and Wm. Henderson to construct an electric light plant.

CHICAGO, ILL.—The Commonwealth Electric Co. has purchased property on Chicago River adjacent to its works, and it will be used for extensions.

PICKNEYVILLE, ILL.—Bids are wanted May 2 for constructing an electric light plant and for power for the city water works pumping station. A franchise will be granted to the operating company for a term of 15 years. Thirty-five arc lights are required for city lighting. Peter J. Hamm is city clerk.

CHICAGO, ILL.—The North Shore Electric Railway has increased its capital stock from $750,000 to $1,250,000, for the purpose of taking over the electric light plants at River Forest, Elmhurst, Melrose Park and Maywood. This will make 16 villages included in the operation of the company, extending from Waukegan down to Evanston and out near the Desplaines River along the western limits of Chicago. A bond issue will also be made in the near future.

EVANSVILLE, IND.—The Jasper Ind., town board, April 13, purchased the electric light plant of that place and it will be operated by the city.

BICKNELL, IND.—The county commissioners have granted J. H. Barr & Co. a franchise to construct an electric light and power plant in Bicknell.

FT. WAYNE, IND.—The Ft. Wayne Electric Light & Power Company has completed its organization and will at once begin the reconstruction of its plant.

BOONVILLE, IND.—The City Light & Power Company, of Boonville, has been incorporated. J. F. Katterjohn, Jno. F. Hepp and S. W. Hart and others are the incorporators.

INDIANAPOLIS, IND.—The Indianapolis Light & Power Company has filed amended articles of incorporation whereby the company's powers are broadened. The amended articles allows the company to mine coal, equip coal mines and other cities with apparatus for electric light and power.

MASON CITY, IA.—The citizens have voted to construct an electric light plant.

FRANKFORT, KY.—The Princeton Electric Light & Power Company, of Caldwell County, has been incorporated with a capital stock of $25,000.

WICKLIFFE, KY.—Bids are wanted May 2 for furnishing one 60-kw alternator; 60-cycle, single-phase engine type alternator, to be connected to and operated by an engine of sufficient proper size; also alternating service system of 25 arc lamps complete, with regulating transformers, 17 arc lamps of 6.6 amp. capacity, etc. G. P. Prentis is chairman of the light committee.

WICOMICO, MD.—The Wicomico Electric Power Co., composed of Chas. R. Disharoon, Jesse D. Price, Thos. Perry, and others, will apply for a charter.

BALTIMORE, MD.—Chief Engineer Phelps has received authority from the electrical commission to make extensions of the house-to-house subway system.

ROCKVILLE, MD.—The Mayor and council of Kensington, this county, have abandoned the idea of bonding the town for $50,000 for the purpose of establishing an electric light and water plant. A bill was prepared to be sent to Annapolis, but met with strong opposition on the part of taxpayers. It was decided by the council to defer the matter indefinitely.

GREENFIELD, MASS.—A committee has been appointed to secure estimates on the cost of installing an electric plant.

WESTFIELD, MASS.—At the annual town meeting April 4 $10,500 was appropriated for installing and operating a municipal power plant. Owen E. Parks is town engineer.

BAY CITY, MICH.—The citizens have voted to issue $50,000 bonds to enlarge the city lighting station for commercial lighting.

IONIA, MICH.—The plant and buildings of the Ionia Electric Light Co. at Wagar's dam, 4 miles east of here, were washed away on March 25. The loss is about $15,000.

ANN ARBOR, MICH.—The Michigan Milling Company and Frank Cornwell are interested in the construction of an electric light and power plant to cost about $150,000.

MARQUETTE, MICH.—It is stated that the municipal electric lighting plant shows a net revenue of nearly $13,000 for the fiscal year just closed with all interest charges defrayed, a liberal allowance for depreciation, bond payment of $5000, etc. It is expected that the plant will ultimately pay off its bonds and reimburse the city for the amount originally invested.

BIRD ISLAND, MINN.—L. A. Tinnes has petitioned for a franchise for an electric light plant.

ATWATER, MINN.—The question of establishing water works and an electric light plant is under consideration by the council.

NEW PRAGUE, MINN.—Bids are wanted April 18 for furnishing and installing an engine, boiler, etc., in the city power house. Albert J. Rynds is city clerk.

ST. PAUL, MINN.—G. S. Edmondstone, 518 Globe Bldg., chief engineer Cannon River Electric Company, writes that the company is preparing to build a dam and power house and install hydraulic and electric machinery for the development of 2000 kw on Cannon River, near St. Paul.

ST. LOUIS, MO.—Application was made in the United States Court to have the Farmington, Mo., electric light and ice company declared bankrupt. The petition was presented by various creditors.

CHARLESTON, MO.—The Southwet Missouri Ice, Light & Power Company has been incorporated with a capital stock of $100,000. The incorporators are Handy Moore, J. E. Armstrong and R. B. Boyce.

MOBERLY, MO.—At a special election April 15, it was voted to grant the Moberly Light, Power & Fuel Company the right to construct, maintain and operate an electric and gaslight, power and fuel plant in Moberly, also to legalize a contract for ten years with the said company.

OSYKA, MISS.—The citizens have voted to issue $15,000 bonds for water works and an electric light plant.

LINCOLN, NEB.—It was voted April 5 to issue $65,000 bonds for the construction of an electric light plant. T. H. Pratt is county clerk.

ATLANTIC CITY, N. J.—The Brigantine Transportation Company, which supplies electric lights to Brigantine, N. J., is to be sold out by the receiver, Mr. R. D. A. Parrott. There is no electric light plant in Brigantine.

MIDDLEPORT, N. Y.—The Albion Electric Light and Power Company has secured the contract for lighting the city by electricity at $60 per lamp per year.

ALBANY, N. Y.—A bill has been introduced in the legislature providing for a commission to investigate the various methods of electric canal boat propulsion and report to the Governor and Legislature early in 1905.

UTICA, N. Y.—The Utica Gas & Electric Company has elected the following-named officers: President, Anthony N. Brady, of Albany; vice-president, William E. Lewis; secretary, W. J. Cahill; treasurer, George H. Stack.

WATKINS, N. Y.—The Watkins Consolidated Gas & Electric Co., Watkins, N. Y., was recently sold by Mr. A. L. Sweeney to the Consolidated Electric Light & Traction Co. of Philadelphia. Mr. Sweeney says that the election which was held in the village recently, at which time municipal ownership was voted for, is undoubtedly illegal in view of the light in which the courts have viewed other similar elections occurring about the same time.

FREMONT, N. C.—The council has under consideration the construction of an electric light plant.

KENMARE, N. D.—F. W. Amsler and A. B. Kerlin, of Devil's Lake, have secured a franchise for an electric light plant.

FREMONT, OHIO.—The Fremont Power & Light Company has been incorporated, with a capital of $350,000, by capitalists of this city, Chicago, Waterloo and Auburn, Ind.

COLUMBUS, OHIO.—A bill has been introduced in the Legislature providing for the appointment of a State franchise commission to control street and interurban railways, artificial gas, electric light, heat, power and water companies.

ST. MARYS, OHIO.—The city council has been asked for an appropriation for the improvement of the water works and electric light plant. It is proposed to purchase two water tube boilers of 300-hp each, one heater and purifier of 600-hp capacity, a smoke-stack, a dynamo, 100 enclosed arc lamps, an air compressor; drilling 3 wells, repairing and extending water mains and electric light lines.

LEWISTOWN, PA.—The contract for arc instead of incandescent lights has been awarded to the Lewistown Electric Light Company at $65 per light.

NEW FREEDOM, PA.—W. H. Lowe, town secretary, writes that it is proposed to construct an electric light plant at a cost of $13,600. Bids will be received April 30.

CRESSON, PA.—The Cresson Electric Light Co. has started operations since the installation of a new power house. Light was formerly supplied from a transmission line at 6000 volts from the Galletyin Electric Light Company's plant, 3 miles away. This line is still maintained for emergency at either end.

LAWRENCEBURG, TENN.—The city council is investigating the cost of establishing an electric light plant.

COLUMBIA, TENN.—Bids are wanted April 23 for furnishing 60 arc lights for a term of 10 years. W. A. Dale is chairman of the committee.

SHERMAN, TEX.—The Sherman Light and Power Company has been organized with a capital stock of $100,000. The incorporators are: J. Lobit, of Galveston; E. P. Bomar, of Gainesville; W. P. Brents, M. B. Pitts and C. N. Roberts, of Sherman.

LOGAN, UTAH.—The citizens have voted to issue $12,000 bonds to complete the municipal electric light plant.

BURLINGTON, VT.—The Northern Electric Co. has been incorporated with a capital of $20,000.

RICHMOND, VA.—C. E. Bolling, superintendent of the water works in his annual report, estimates the cost of constructing an electric light plant at about $150,000.

MILWAUKEE, WIS.—The citizens voted April 5 to issue $500,000 bonds for municipal lighting plant.

CLINTON, WIS.—There is no electric light plant in this place, gas being now the only medium of illumination.

LADYSMITH, WIS.—The Ladysmith Light & Power Co. proposes to re build its power house, recently burned, to cost about $3000.

ANTIGO, WIS.—Mr. W. L. Elliott, proprietor of the electric light plant in this place, died last January and the estate is now in probate. Mr. John Wright is manager.

LAKE GENEVA, WIS.—The Lake Geneva Water & Light Company supplies 27 arc lights for street lighting and 15 for private use. The company runs on the moonlight schedule and until midnight, the city paying $75 per year for its lights.

ORILLIA, ONT.—The town of Orillia is now practically without light and power, the big concrete dam of the municipal electric plant at Ragged Rapids, on the Severn River, having given way on April 7. The repairs to the dam will probably cost upwards of $10,000. The town's old steam pumping plant will keep up the supply of water and a limited amount of light in the meantime, while the various industries, dependent on the municipal electric plant for their light and power, will put in temporary steam plants.

THE ELECTRIC RAILWAY.

LEWISTON, IDAHO.—Judson Spofford and associates have asked the city council for a franchise for an electric street railway. The petitioners represent the Lewiston & Southeastern Electric Railway Company, which has completed a survey and is now ready to promote the building of an electric railway between Lewiston and Grangeville, with a branch line running to Nez Perce.

KEWANEE, ILL.—The Galesburg & Kewenee Railway Company has announced that a number of improvements will be made soon, among them the completion of the line to Galva.

GALESBURG, ILL.—Plans are now being made by the promoters of the Western Illinois Traction Company for the taking up of the construction work on the lines in this city and on the interurban right of way between Monmouth and Galesburg, where it was left last fall.

INDIANAPOLIS, IND.—The Indianapolis & Northwestern Traction Company re-elected the present officers. A number of extensions will probably be made to the system this season.

EVANSVILLE, IND.—The Evansville & Eastern Electric Railway Company has incorporated to build an electric railway from Evansville to Rockport. The officers are: J. C. Haines, president; J. W. Fuquay, vice-president; M. S. Sontag, treasurer; L. C. Frick, secretary; W. I. Rudd, F. W. Reitz and W. L. Sontag, directors.

TRIPOLI, IA.—A company is being organized here for the purpose of building an electric railway from Anamosa to Tripoli, and up the river to Nashua and Mason City.

IOWA CITY, IA.—The citizens of this city, April 8, voted a twenty-five-year franchise to the Muscatine, Iowa City & Davenport Electric Railway Company. The surveys for the line have been completed and a large portion of the right of way acquired.

ANNAPOLIS, MD.—A bill has been introduced in the House to incorporate the Stewartstown & Susquehanna Railway & Power Company. The incorporators are: Thomas Mackenzie, Harry M. Benzinger, Joseph W. Galbraith, Clarence B. Hight, E. E. Mackenzie, Harry E. Kerr and Thomas H. Robinson. The capital stock is $10,000, with privilege of increasing it to $500,000.

BOSTON, MASS.—The Hartford & Springfield Street Railway has voted to purchase the property, franchise and rights of the Somers & Enfield Electric Railway Company for $165,333.33.

TRENTON, N. J.—Colonel Michael Hurley, of Trenton, has been awarded a contract to build the electric railway from Lakewood to Point Pleasant. This is part of the system to connect this city with towns along the Atlantic coast.

BUFFALO, N. Y.—Fire last week destroyed the paint shop and about thirty trolley cars belonging to the International Railway Company at Cold Spring in this city. The loss is estimated at from $100,000 to $150,000.

LONG ISLAND CITY, N. Y.—The electrical committee of the Long Island Railroad Company has passed resolutions directing the purchasing agent of the road to buy material for two or three of the sub-stations, one at Hammells and one at Woodhaven. This is the beginning of the work of introducing electric power on the Long Island road between Long Island City and Far Rockaway.

FARGO, N. D.—Contractor James Kennedy has been authorized by the Fargo & Moorhead Street Railway Company to purchase materials and supplies for the construction of the system.

CLEVELAND, OHIO.—The council of the village of Euclid Heights has granted a franchise to the Shaker Lakes & Boulevard Street Railway Company.

DAYTON, OHIO.—The Dayton & Western Traction Company is erecting an addition to its main power station at West Alexandria, Ohio, and will install two 450-hp Hamilton Corliss engines, two 250-kw generators and two 250-hp Babcock & Wilcox boilers. The additional equipment was made necessary by the recent extension of the road to Richmond, Ind.

TOLEDO, OHIO.—At the annual meeting of the stockholders of the Toledo & Indiana Railway it was announced that a bonding concern had submitted a proposition for financing the proposed extension of the line from Wauseon to the Ohio and Indiana State lines. The matter of a location for the power house, and the other improvements will be acted upon as soon as the financial deal has been disposed of. The Arbuckle-Ryan Company, of Toledo, is preparing preliminary plans for the new power station.

MONONGAHELA, PA.—A new trolley line is to be constructed from Monongahela to Ellsworth by way of Bentleyville by a company known as the Monongahela, Bentleyville & Ellsworth Street Railway Company. The road is to be 15 miles long.

LANCASTER, PA.—The directors of the Mount Joy & Lancaster Street Railway Company have elected Charles B. Keller president to succeed W. B. Given. The committee on rights of way reported that nearly all the rights of way along the Marietta pike could be secured.

CONNELLSVILLE, PA.—A Pittsburg syndicate plans to build an electric railway from Connellsville to Ohiopyle and develop the water falls at the latter place. With 1250 ft. of tubing a fall of 90 ft. can be secured. Power will also be supplied to other railways and industries in Western Pennsylvania.

DOYLESTOWN, PA.—Application has been made to the Court of Common Pleas of Bucks County, Pa., for the appointment of a receiver for the Doylestown & Willow Grove trolley road, on the ground that the road was sold without warrant under foreclosure proceedings to Messrs. Widener & Shelmerdine for $50,000.

ALLENTOWN, PA.—The Mauch Chunk, Lehighton & Slatington Street Railway Company, now in a receiver's hands, was sold at public sale here April 12, under foreclosure proceedings brought by the West End Trust Company, of Philadelphia, for $150,000, to Thomas Keck, of Orange, N. J.; J. M. Dreisback, of Mauch Chunk, and Sol H. C. Trexler, of Allentown, a committee representing the bondholders.

ALLENTOWN, PA.—It is expected that the reorganization plan of the Lehigh Valley Traction Company, now in the hands of receivers, will soon be developed. It is probable that the Easton Consolidated Electric Company will be allowed to revert to its original owners. The reorganization plan contemplates the erection of a central power house, and this will bring the cash requirements up to about $1,500,000.

MONTREAL, QUE.—The Montreal Terminal Railway Company intends to make extensions in the northern counties of the Province of Quebec. A bill is now before the Dominion Parliament to grant power to the company to extend its system.

TORONTO, ONT.—Messrs. Royce and Henderson, of Toronto, have given notice of an application to the Legislature for power to extend the Toronto Suburban Railway through Hamilton, passing though the counties of Wentworth, Lincoln, and Welland to Niagara Falls, in or to some point on the Niagara River. The company also wants permission to build to Vaughan Township, and to Brampton, in Chinouacousy Township.

New Industrial Companies.

THE NORTHERN ELECTRIC COMPANY, of New York, has been incorporated, the capital stock being $10,000. The directors are: T. J. Ryan, L. Barnes, Jr., and G. A. Schriefer, of New York.

THE MARINE MAGNETIC CONTROL COMPANY, of Brooklyn, N. Y., has been incorporated with a capital stock of $100,000. The incorporators are: Albert Graham, Edward Pfuhler and Arthur J. Raymond.

THE KINETIC ENGINEERING COMPANY has been incorporated in New York with a capital stock of $10,000, the directors being R. P. Elliot and Georgiana Elliot, of New York, and J. G. Blerck, of Philadelphia.

THE CALDWELL & OSTERHOUDT CORPORATION, of New York, has been incorporated to deal in electrical supplies. Capital, $5,000. Directors: R. L. Caldwell, Summit, N. J.; H. B. Osterhoudt and P. A. Overbaugh, Brooklyn.

THE MICHAELSON INSTRUMENT COMPANY, of Jamestown, N. Y., has been incorporated to manufacture electrical instruments, the capital being $25,000. The incorporators and directors for the first year are: J. Michaelson, C. Jacobson, of Warren, Pa., and J. B. Fisher, of Jamestown, N. Y.

THE TELEPHONE ELECTRIC TOLL BOX COMPANY has been incorporated at Trenton, N. J., for the purpose of manufacturing telephone boxes and apparatus. The capital stock is $125,000 and the incorporators are: Chas. L. Walton, Romeo B. Haziett, of Trenton; Eli H. Chandler, Atlantic City.

Legal.

CHICAGO TELEPHONE RATES.—The Chicago Telephone Company has lost an important suit. Judge Mack has decided that the maximum price of telephones applies to all districts annexed to Chicago since the original franchise. This cuts out all toll charges and increases the gross receipts on which the company pays the city three per cent. compensation.

CITY OWNERSHIP IN CONNECTICUT.—The Supreme Court of Connecticut has upheld the constitutionality of the law providing for municipal ownership of lighting plants in instances where the citizens vote to purchase an existing private corporation. At the same time the court has decided that the city of Norwich must buy the Norwich Gas & Electric Company at a cost of $590,000, plus the value of supplies on hand, this figure having been made by a committee on appraisal, or must pay the company $190,000 and leave the property in the hands of the bondholders. The amount of the bonds of the company is $400,000, secured by a mortgage. The value of the supplies on hand is about $20,000.

SELF-RESTORING DROP PATENT.—A further decision has been given in the Fisk patent, No. 521,461, granted June 19, 1894, relative to the self-restoring or "Express" type of telephone board drop. In June, 1897, the Western Telephone Construction Co., owners of the patent, brought suit in the United States Court against the American Electric Telephone Co., P. C. Burns, W. C. Meissner and others. The complainant company passed through troubles, and was reorganized under the name of the Western Telephone Mfg. Co. in the fall of 1902. Thereupon a more vigorous prosecution of these suits was undertaken and within another year Judge Kohlsaat gave a decision, holding that the patent was good and valid, but that defendants did not infringe it. The Western Telephone Mfg. Co. appealed to the United States Court of Appeals, which latter heard the oral arguments on Jan. 20, 1904, Judges Jenkins, Grosscup and Baker sitting enbanc. The lawyers on both sides presented elaborate arguments, briefs and testimony. Mr. C. W. Bulkley was attorney for the defendants and Mr. Josiah McRoberts for the complainant. On April 12, Judge Baker rendered the opinion of the Court, reversing the lower Court with directions to enter an order for an injunction and an accounting in favor of the Western Telephone Mfg. Co.

DEATH FROM TELEPHONE WIRE.—In a decision for the Texas Telephone Company, the Court of Civil Appeals of Texas held: 1. As liability for wrongful death is created alone by statute, and limited to carriers, a telephone company is not liable for a death resulting from negligence of its employee. 2. In an action for death caused by deceased having come in contact with a live wire owing to the alleged negligence of defendant, plaintiff requested an instruction applying the law to the alleged negligence of defendant in selecting its inspectors and lamp trimmers. The instruction included two servants, and, while there was evidence tending to show negligence on the part of one of them, there was no testimony tending to show negligence on the part of the other, and no evidence tending to show negligence on the part of defendant in employing them. Held, that the instruction was properly refused. It was shown that John H. Fisher's death was caused by an electric shock received by him from a telephone wire which he saw hanging in a tree, and voluntarily reached up and caught hold of. The testimony tends to show that the wire referred to carried a dangerous current, resulting from the fact that at a place some distance from where the accident occurred the telephone wire was in contact with an electric light wire owned by the gas company. The undisputed testimony shows that several hours before the accident the deceased's son received an electric shock near where the deceased met his death; that deceased had been apprised of that fact, and he and the person who informed him were then engaged in searching for the live wire, the informant having warned him that the wire was dangerous. While engaged in the search, the deceased saw a telephone wire hanging in a tree, reached up and caught it, and received the shock which caused his death.

TELEPHONE RATES.—In the appeal of the Maryland Telephone & Telegraph Company against a decision as to telephone rates in Baltimore, the Court of Appeals of Maryland has filed a decision of which the gist is as follows: 1. Acts 1892, p. 535, c. 387 (Code Pub. Gen. Laws 1903, art. 23, §§334-338), limits the rates of charges for the use of telephones, and defines "telephone" as used in the act. Acts 1894, p. 260, c. 207 (Code Pub. Gen. Laws 1903, art. 23, § 339), provides that contracts may be made for such special form of telephone service at such rates as may be agreed on, provided the obligation of telephone companies to furnish, at the rates mentioned in the former act, the kind of telephone service now provided by the Chesapeake & Potomac Telephone Company at such rates, shall not be impaired. Held, that an ordinance limiting a company's rates of charges for telephone service is not, by these statutes, restricted in its application to the kind of telephone described in them. 2. Where an ordinance limited the rates a company might charge for telephone service, the defense, in a suit to enjoin it from charging higher rates, that in view of the conditions existing when the ordinance was passed it should be construed as applying to a particular kind of service different from that furnished to the complainants, cannot be set up by demurrer, but only by answer. 3. Under Code Pub. Loc. Laws, art. 4, § 819a, providing that the mayor and city council of a city shall have power to regulate the use of the streets for telephone poles and wires, they have authority to impose on a company, as a condition of such use, limitations of its rates of charge for telephone service. 4. After a telephone company has accepted an ordinance imposing limitations of its rates of charge, it is estopped to deny the validity of the ordinance on the ground that the rates fixed are not reasonable. 5. Where an ordinance limits the rates of charge by a telephone company, an individual may maintain a suit to enjoin it from charging him higher rates than those fixed by the ordinance. 6. A bill by several parties to enjoin a telephone company from charging them higher rates than a city ordinance permits is not multifarious, though it alleges a contract by each of them with the company.

Obituary.

MR. F. W. SANGER.—We regret to note the sudden death from pleuro-pneumonia of Mr. F. W. Sanger, general manager of Madison Square Garden and theatre. He was a well-known actor at one time, afterwards a manager, and about 1893-4 became connected with the Garden. During his tenure of office he made many friendships among electrical men and automobilists, who met him at the various exhibitions.

MR. F. W. SABOLD.—Frank W. Sabold died at Albany, N. Y., on April 16, aged 47 years. He was considered one of the best telephone and telegraph men of his day. When the American-Union Telegraph Company was organized he was made manager of the Indianapolis (Ind.) office. The Western Union Telegraph Company absorbed the American-Union in 1882, and Mr. Sabold was made manager of the Albany office. In 1890 he became manager of the Westchester Telephone Company. After its absorption by the New York Telephone Company he became superintendent of the Westchester division. Since 1902 he had been contract agent for the Hudson River Telephone Company.

Personal.

MR. FRANK SUTTON, consulting electrical engineer, etc., has removed his offices in New York City to rooms 801-804 Nos. 91-93 Wall Street.

MR. C. H. MACKAY, president of the Commercial Cable Company, etc., has been elected a trustee of the New York Life Insurance Company in place of the late W. R. Grace.

SARGENT & LUNDY, of Chicago, announce that about May 1 they will occupy new quarters on the seventeenth floor of the Railway Exchange Building, Jackson and Michigan Boulevards.

MR. F. SARGENT, the consulting engineer, of Chicago and New York, has just reutrned from Europe, where he has spent some weeks, chiefly with a view, it is said, of studying up steam turbine and central station development there.

PRES. B. J. ARNOLD, of the American Institute of Electrical Engineers, opened the Pittsfield chapter on April 18, assisted by Dr. F. A. C. Perrine and Messrs. Pope, Rushmore, Dodd, Andrews and others. There was a large and enthusiastic attendance.

MR. J. F. LAWLESS, manager of the San Francisco Gas & Electric Company, has tendered his resignation to take effect at once. He was appointed in October, 1903. There are rumors of internal friction. It is reported that Mr. S. L. Napthaly, in charge of the electrical department, may succeed him.

MR. PUTNAM A. BATES, who resigned as sales manager of the Crocker-Wheeler Electric Company just before going abroad, has returned from a holiday trip of several weeks, nearly all of which was spent in England, where Mr. Bates has many friends. He is much improved in health by the rest and change.

MR. T. M. MESTON, secretary of the Emerson Electric Mfg. Company, of St. Louis, was in New York City some time last week, at the Eastern headquarters. He reports the outlook as excellent for both the company's direct and alternating current motors, etc. During his stay, Mr. Meston was a visitor at the Engineers' Club.

MR. G. W. DAVENPORT, vice-president of the Niagara Power Company, was in New York City last week, and attended the meeting of the Institute Committee which is making elaborate preparations for the reception of foreign guests this year at the time of the Electrical Congress. Mr. Davenport has guaranteed to turn on the Falls when the visitors reach his bailiwick.

MR. SAMUEL INSULL, president of the Chicago Edison Company, has sailed for England with his family, and will take a well-earned vacation in that country until early in June. The work of the last year or two has been very exacting, while the responsibilities connected with his great new turbine plant on the Chicago River have been of an unusually novel and onerous character. The fact that Mr. Insull now indulges in a brief vacation shows that he considers the station to be an unquestionable engineering and financial success.

MR. C. E. BROWN, electrical engineer of the Canadian Electrothermic Commission, on the manufacture of iron and steel by electricity, has returned from Europe, and is now at Ottawa at work on the findings of the Commission, whose report is awaited with great interest.

MR. G. L. CROSBY has opened an office at 426 Williamson Building, Cleveland, Ohio, for the Weston Electrical Instrument Company, and will handle the "G-I" Company's circuit breakers. Mr. Crosby will cover a territory comprising western Pennsylvania, Ohio and Michigan, and having previously handled similar lines for about one and a half years, is thoroughly familiar with the circuit breaker and instrument business in that territory.

LIEUT. G. C. SWEET, U. S. N.—By May the new system of wireless telegraphy at Mare Island, California, will be in full operation. Lieutenant G. C. Sweet, United States Navy, is at Vallejo, Cal., superintending the installation of the system. It is understood that when Lieutenant Sweet finishes the installation of the Marconi system at Mare Island and at the Yerba Buena naval Training station in San Francisco bay, he will be sent to Guam and the Philippines by the Naval Bureau of Equipment to supervise similar work at the naval stations there.

MR. F. E. DRAKE, president of the Lanyon Zinc Company, of St. Louis, the largest producer of spelter, etc., in this country, has been visiting New York City the past week, in order to attend and hold the annual meeting of the company. He has scored a notable victory recently in patent litigation, in sustaining the right of his company to use mechanically operated ore roasting furnaces, with means for stirring and advancing the ore. The case had originally been decided against the company, but Mr. Drake appealed it and has won out, as to all the points in contest.

MR. E. P. THOMPSON has been very much interested to see the manner in which his suggestions as to the effect of rays on the insect world have been taken up in the scientific and popular press. He hopes to make some experiments in that field. As a striking illustration of the manner in which members of the American Institute of Electrical Engineers may be ranked as inventors, it is very interesting to note the fact that Mr. Thompson himself has appeared before the U. S. Patent Office on behalf of no fewer than 48 full members and 25 associates. This little fact in itself is good evidence of the mental activity characterizing that body.

MR. W. RUTHERFORD, general manager of Dick, Kerr & Co., the great English electrical and street railway contractors and engineers, is now in this country on a brief trip, accompanied by his wife. He is visiting various parts of the country, including Montreal and Chicago. Mr. Rutherford may be said to have won his electrical spurs on this side, as electrical engineer for the Canadian General Electric Company, for whom he did some pioneer electric railway work in the Dominion, including the famous road along the Niagara Gorge from Chippewa to Queenstown. He went back to England some years ago, and his rise in the profession has been both brilliant and rapid.

REAR ADMIRAL MELVILLE.—The well-known artist of *Punch*, Mr. E. T. Reed, drew a special sketch for the menu of a dinner tendered to Rear Admiral George W. Melville, U. S. N., retired, at the Hotel Cecil, in London, on April 14, by the Institute of Naval Architects. The sketch showed a bust of Admiral Melville overlooking the polar sea, with one or two bears and ships enlivening the ice and seascape. His bust stood on a pedestal draped with the British and American flags, and beside the pedestal John Bull and Uncle Jonathan, depicted in Mr. Reed's best manner, were clinking glasses. The proceedings were more or less private and informal. About 40 persons sat down to dinner, among them being Lord Glasgow in the chair, who had Admiral Melville on his right hand and Mr. Henry White, of the United States Embassy, on his left. Lord Selborne, First Lord of the Admiralty; Admiral Sir John Dalrymple Hay, Lord Graham, Admiral Sir John Hopkins, Major Beacon, the United States Military Attache; Mr. George Westinghouse, Mr. W. I. Buchanan, of the British Westinghouse Company, and Sir John Thorneycroft. Rear Admiral Melville, spoke during the proceedings, which wound up with a conversazione.

EDUCATIONAL.

COLUMBIA UNIVERSITY, N. Y.—The heads of the departments of civil, mechanical, electrical and mining engineering and of metallurgy have been assigned to seats in the Faculty of Pure Science. This important step was taken upon the joint recommendation of the Faculties of Applied Science and of Pure Science, and marks the recognition of research work in the various technological fields as on the same plane with research work in the various departments of what is ordinarily known as pure science. Hereafter all graduate work for the degrees of Master of Arts and Doctor of Philosophy at Columbia, when taken in any branch of science, will be under the jurisdiction of the Faculty of Pure Science. The Faculty of Applied Science will remain a strictly technological Faculty.

Trade Notes.

THE MAGNET WIRE COMPANY has removed its New York offices from 80 William Street to 42 Broadway.

THE WHEELER CONDENSER & ENGINEERING CO. has moved its local quarters from 120 Liberty Street to 42 Broadway, New York.

SHEPHERD ENGINEERING COMPANY, of Franklin, Pa., has opened a branch office in the Witherspoon Building, Philadelphia, with Mr. Edward D. Skidman in charge.

AUTOMATIC SWITCH CO., of 131 Liberty Street, New York City, notifies us that the officers of the concern are: President, G. H. Whittingham; treasurer, C. K. Harrison; secretary, W. H. Judd.

H. T. PAISTE CO., of Philadelphia, has issued three very neat and attractive blotters in regard to its brass cap P.K. fuseless attachment plug, flush wall box receptacle, etc. Each blotter has a little calendar down in the right-hand corner.

STANLEY & PATTERSON are vacating 93 Liberty Street in order to secure more commodious premises at 40 Cortlandt Street, where they will occupy the first floor, ground floor and basement. The factory will remain at 35 Vesey Street, New York.

COVINGTON MACHINE CO., Covington, Va., will engage, we are informed, in the manufacture of a complete line of high-grade self-oiling steam engine on which it holds the patents. It will give special attention to the electrical field. The engine is designed for direct connection. It will also build a medium speed automatic Corliss engine which has already had from 12 to 14 years' service and is therefore well tested.

JAMES S. BARRON & CO., West Broadway and Franklin Street, New York City, have had to leave that address on account of the fire that destroyed their building and all its contents on April 8. The damage, amounting to $185,000, was fully covered by insurance. They are again in running order at 339 Greenwich Street, corner of Jay, and expect to remain there until the completion of their new building on the old site, about May 1, 1905.

THE TOLEDO STORAGE BATTERY AND ELECTRIC COMPANY, Toledo, Ohio, has been organized to manufacture the new Miller storage battery and to deal in general electrical supplies. It is stated that by the Miller process a superior quality of battery plate is produced. The officers of the company are: Mark H. Griffin, president; L. A. Alexander, vice-president; G. J. Miller, general manager; Chas. R. Clapp, secretary, and J. T. Greene, treasurer.

THE INTERNATIONAL TELEPHONE MFG. COMPANY, Chicago, is having a constantly increasing demand for its new self-restoring drop switchboard equipment. In the International drop, the shutter is automatically restored by a small trigger mounted between the jack springs in the path of the plug. The operator's answering plug, not coming in contact with the shutter, it is claimed, makes this one of the most positive mechanical self-restoring drops on the market.

BATTERY FLUIDS.—Franklin H. Kalbfleisch Co., 31 Burling Slip, New York, has issued a neat pamphlet entitled "Eleven Years of Progress" and dealing with its specialties as manufacturing chemists, including sulphuric acid, muriatic acid, nitric acid, pure electrolytes, distilled water, battery solutions of all kinds, electropoin fluid, chromate salts, etc. The pamphlet is illustrated with views of its various factories and gives an excellent idea of its wide range of output.

THE WARD LEONARD ELECTRIC COMPANY has invented a resistance unit to replace tubular resistance lamps. This unit has, it is said, all the advantages of an enclosed, hermetically sealed resistance and the added advantages that the resistance wire has a practically zero temperature coefficient, and does not deteriorate due to passage of current. It is a permanent resistance, smaller than a tubular lamp and very strong mechanically. The resistance wire is wound upon a porcelain tube and enamelled. Telegraph and telephone companies are using this type of resistance in large quantities.

DODGE & DAY.—The New Haven Manufacturing Company, New Haven, Conn., of which Mr. Leslie Moulthrop is general manager, has had Dodge & Day, modernizing & contracting engineers, Philadelphia, Pa., go over its entire equipment with a view of bringing it up to date in every respect. Complete interior arrangement of the shops is contemplated, and it is probable a number of the old machine tools will be replaced by modern apparatus. Dodge & Day have also been commissioned by the Meadville Vise Company, Meadville, Pa., to re-design a number of its machine tools. Mr. Dodge, who is now making an extensive trip through the New England states, in response to numerous received, reports a growing improvement in the machinery trade throughout the country.

WESTERN ELECTRIC CO. has issued Bulletin No. 2015 of March, 1904, devoted to its Type L direct driven generators for lighting and power. These are of large size and have the field frame divided vertically, so that the yoke can be drawn apart horizontally allowing the armature to be easily withdrawn for removal or inspection. The laminated pole pieces are carefully built up. The armature is of the iron-clad type, the core being thin discs of doubly annealed sheet steel. The coils are solid bars of specially drawn copper enlarged in cross section at the ends. The brush holder ring is carried in supports projecting from the yokes the entire device being moved around the commutator by means of a hand wheel at the side. By means of eccentric insulated bushing, each individual arm may be adjusted to obtain perfect uniformity of spacing. The machine is illustrated in perspective and by diagram and dimensions are given for a variety of sizes at 125 and 250 volts.

ELECTRICITY IN VAUDEVILLE.—Few people have an idea of the extent to which the development of the vaudeville or continuous performance houses has been of benefit to the various applications of electricity. The manager of a circuit such as the Proctor theatres, consisting of 7 houses in 4 different cities, has at his command an army of no small proportions. Those actually employed in the stage performances average forty each week. To this must be added the property men, scene shifters, clearers, electricians, stage and assistant stage managers. All the houses are electrically lighted. There are from thirty to forty men throughout the auditorium to cater to the comfort and convenience of the patrons, possibly ten more employed as door keepers and ticket sellers, a business staff of from five to eight, and an orchestra of ten players. In addition to this there are three complete shifts of scenic artists employed in New York City on the paint bridges at the Fifth Avenue Theatre, Fifty-eighth Street and One Hundred and Twenty-fifth Street Theatres, a staff of fifty house painters and decorators, who are constantly going over the houses and keeping them in good condition; a dozen char women, and a host of advertising men, booking agents and others. These are all necessary in the presentation of a complete and perfect performance, and yet Mr. Proctor finds it profitable to present expensive bills at trifling admission fees, while paying the salaries of more than twelve hundred employees each week.

THE F. BISSELL CO., Toledo, Ohio, has recently issued two bulletins for its perpetual calendar. No. 27 relates to field regulators, theatre dimmers, etc., and No. 37 to house goods, such as annunciators, bells, pushbuttons, etc.

THE STANDARD ELECTRICAL MANUFACTURING COMPANY, of Niles, Ohio, has established its New York office at 19 Park place, and not 19 Park Row, as recently stated in this column.

CRANES.—In a recently issued catalogue the Northern Engineering Company, Detroit, Mich., gives several full-page half tone illustrations showing actual installations of its traveling cranes in power houses, shops, etc. The company also makes cranes for foundries, machine shops and industrial plants.

THE NERNST LAMP COMPANY has recently removed its Boston office from 131 State Street to No. 501 Atlantic Avenue. The office will, as heretofore, be in charge of Mr. Geo. C. Ewing as district manager, and will carry a complete stock of Nernst lamps and supplies, insuring prompt service to customers.

CEILING FANS.—Messrs. E. B. Latham & Co., 39 Vesey street, New York, have issued a pamphlet, giving illustrations, prices and other information regarding Tuerk alternating current ceiling fans. These fans are made with two and four blades, with and without electrolier attachment. This list refers to the 1904 model of fans.

THE LAHMEYER ELECTRICAL COMPANY, Ltd., 109 Oxford street, London, Eng., has issued an illustrated price list of its controllers and other apparatus for electrically driven cranes, hoists, lifts and other variable speed machines. Various types of controllers are illustrated, and many diagrams give the dimensions of the different sizes.

THE FARR TELEPHONE AND CONSTRUCTION SUPPLY COMPANY, Chicago, recently issued some illustrated and descriptive matter regarding some of its goods. The sheets are indexed in a unique manner, to facilitate ready reference. The line of goods represented includes batteries, linemen's tools, transmitters and receivers, line supplies, switchboards, etc.

AMERICAN STREET RAILWAYS.—Poor's Railroad Manual Company, New York, has just reprinted as a separate volume the section of its Manual of Railroads devoted to city and suburban electric and other surface and elevated railways. It is brought out under the title "Manual of American Street Railways," and contains much information relating to mileage, equipment, capitalization, etc.

ELECTRIC SIGNS.—The Federal Electric Company, Chicago, is distributing sets of its bulletins of its electric signs, bound with McGill fasteners. New bulletins can be readily added to the set. Its signs are all metal and waterproof, and are especially adapted for out-of-door displays. The company also manufactures a combination clamp shade for incandescent lamps, which is described and several designs illustrated.

THE INTERSTATE ELECTRIC COMPANY, LTD., Baronne & Union Sts., New Orleans, La., has just let the contract for the erection of what it claims will be one of the largest buildings in the United States used for the electrical supply business. The building will be 100x100 ft. and five stories high. Mr. P. Stern is general manager of the company, which does construction work as well as carrying on a general supply business.

HEATING AND VENTILATION.—Mr. W. H. Carrier, M. E., read a paper before the convention of the American Foundrymen's Association at Milwaukee in June, 1903, on the subject of heating and ventilation of factory buildings. This paper has been reprinted in pamphlet form by the Buffalo Forge Company, of Buffalo, N. Y. This company's system is used in the locomotive repair shops of the New Jersey Central Railroad at Elizabethport, N. J. The reprint is illustrated.

THE BUFFALO FORGE COMPANY, Buffalo, N. Y., has recently issued two neat booklets referring to "Buffalo Disk Wheels" and "Buffalo Improved Ventilator." The disk wheels deliver air in a direction parallel to the axis of rotation, and for this reason are well adapted for many situations. Copies of these booklets can be had on application.

ZINC.—The Lanyon Zinc Company, of St. Louis and New York, has issued a handsome brochure bearing the title, "Two Stories of Zinc," which will be found of especial interest to those who would know the processes of zinc manufacture from ore to merchantable product. The first section treats of the first stage of manufacture, ending in spelter as a product; and the second of the various steps in the making of sheet zinc. The processes are described in much detail, and with the aid of a number of excellent engravings.

NAME PLATES.—The Crowe Metal Manufacturing Company, Chicago, has recently issued a catalogue giving many facsimile reproductions of name plates manufactured by it. There seems to be no limit as to the design of these plates, many of them being of very artistic get-up. The gilding against the black sets off the illustrations very effectively. Among the plates illustrated we notice the names of the Ewing-Merkle Electric Company, St. Louis; Western Electric Company, Moore Telephone and Cabinet Company, Caro, Mich.; the Cutler-Hammer Manufacturing Company, Milwaukee, and several other well-known electric concerns.

CHICAGO & ALTON CARS.—The Chicago & Alton Railway was the first line to run Pullman sleeping cars, dining cars and chair cars. The C. & A. was also the first line to establish a modern surgical system and the first, and so far the only line, to equip all of its locomotives with electric headlights. This leading thoroughness is to be immediately supplemented by the equipment of all cars in all trains with electric lights. Mr. C. A. Goodnow, the "Alton's" new general manager, has ever been regarded as the exponent of electric lighted trains, and has selected for the "Alton" a system by which the current is produced by a dynamo driven by the axle during the run of the train.

THE BURT MANUFACTURING COMPANY, Akron, Ohio, has received recently among other large foreign orders, one from its agent in Durban, South Africa, for 30 gross of Cross oil filters, and another from its agent at St. Petersburg, Russia, for oil filters for the Russian government. The company is sending out an interesting picture showing a 30-inch exhaust head, recently made by the Jones and Laughlin Steel Company, of Pittsburg. The head is 10 ft. high, 9 ft. 4 in. in diameter, and weighs 2700 pounds. Mr. W. F. Warden, president of the company, sailed April 15th on a trip to Europe, where he will visit the numerous agencies there of his company. In his absence Mr. J. Asa Palmer, secretary of the company, will have full direction of its affairs.

LAMP SOCKETS.—We have received the following from Mr. J. L. Yost, general manager of the Yost Electric Manufacturing Company, of Toledo, Ohio, under date of April 2: "We note the appearance of the Perkins Electrical Switch Manufacturing Company advertisement in several of the electrical publications advising the buyers generally, or the sellers of Yost sockets that suit has been decided against J. F. Buchanan & Co. for selling Yost sockets and that the sellers of Yost sockets are infringers on their patent '626,927.' This is not true. The Yost Electric Manufacturing Company never made this socket on which J. F. Buchanan & Co. were sued for infringement, and are not making it now. It is not the Yost socket, but was known as the Dixon Socket, made by the Yost-Miller Company, and not by this company at all."

MURRAY CORLISS ENGINES.—Another example of the modern trade publication which embodies the highest expression of the printing and engraving arts is a recent publication of the Murray Iron Works, Burlington, Ia., describing the Corliss engines and high-pressure boilers that have made the works of this company perhaps better known throughout the country than any other manufacturing establishment in Iowa. That the wide recognition is well merited will, we believe, be evident to the reader of the description given of the design of the Murray Corliss engine, both with respect to valve details and frame construction. Well-tried improvements over the old Corliss type are embodied in almost every part of the engine; and the clear descriptions with accompanying engravings bring out forcefully the merit of the improvements.

TELEPHONE INSTALLATION DIAGRAMS.—Bulletin No. 149 of the Holtzer-Cabot Electric Company, Boston, Mass., is of more than ordinary value and interest. It opens with a general discussion on the wiring and installation of interior telephones. Three systems are considered, viz.: intercommunicating, speaking tube and central switchboard, each illustrated with wiring diagrams of exceptional clearness. There are 19 of these diagrams, and they will be of much value to those interested in and installing Holtzer-Cabot apparatus. The concluding pages give very clear directions for the installation of the apparatus. The Holtzer-Cabot Company evidently appreciates the fact that a clear illustration conveys more information to the mind than pages of cold type, and has made the best of this knowledge in this instance. This bulletin will be well worth careful preservation, and a copy of it should be in the hands of all practical telephonists.

HABIRSHAW WIRES AND CABLES.—A handsome and quite original illustrated catalogue, compiled by Mr. T. J. Hall, has just been issued by the India Rubber & Gutta Percha Insulating Company, with regard to its well-known and widely-used Habirshaw wires and cables, made at the Glenwood Works, Yonkers, N. Y. The catalogue is in quarto form and all the illustrations of cables, testing apparatus, etc., are actual photographs carefully inserted into the descriptive tests. These cables are in great variety, and belong to some of the most important installations in the country, such as Niagara Power, Manhattan Elevated, New York Edison, U. S. Signal Service, Telluride Transmission, heavy telephone cable, etc. Full data are given as to these, each exemplifying some distinct type of work. At the end is a list of some typical plants wired with Habirshaw wires and cables, such as the White House, Washington, or Marshall Field's store, Chicago. The cover is stiff boards, in white, lavender and dark blue—altogether a perfect specimen of quiet good taste.

"BETTERMENT REPORTS."—A unique circular has been issued by Dodge & Day, modernizing engineers, Nicetown, Philadelphia, Pa. It is a "report" on their "Betterment Reports." Betterment reports are made on shop conditions and deal with the numerous factors which, together, make up the complete manufacturing plant. This "report" consists of an outline of the firm's methods of investigating and studying existing conditions and developing plans for their betterment. Shops and businesses of all kinds are brought up to their highest state of efficiency, all existing weak points being modified to produce the best results. No department escapes the searching scrutiny for leaks and defects The "report" is gotten up in a model form, too. It represents an actual report to a client, being printed in typewriter type, with the usual red ink emphases. There are several illustrations showing typical modern shops, and graphical charts which facilitate the mental comprehension of organization of the different departments of a business, processes in manufacturing, etc. The cover of this "report" gives a good idea of the scope of Dodge & Day's work. The report is well worth careful perusal by any engineer.

FOOS GAS ENGINE CO.—A number of prominent representatives of electrical manufacturing companies recently visited the plant of the Foos Gas Engine Company, of Springfield, Ohio, and were invited to inspect the "Special Electric" gas engine which will be sent to the St. Louis Fair as part of the exhibit of this company. The engines is of 22-hp. capacity and will be equal to 200 sixteen candle power incandescent lights when belted to a generator of standard make. The tests show unusual regulation for small gas engine practice, the character of the lighting being commented on by those present as highly satisfactory for commercial work. The engine is of the four cycle type with a throttling admission valve, making periodical explosions of varying intensities. It is equipped with specially heavy fly wheels of large diameter. There were also dsplayed some 20 commercial engines on the testing floor, and about 100 more ready for stock shipment. The engines of this company cover a range in capacities of four to eighty horse power and the intention is to actively enter the "Special Electric" engine in the lighting field. Among the electric companies represented were: the Jenney Electric Company, by Mr. Chas. L. Jenney, president; the Akron Electric Company, by Mr. F. B. Duncan, general manager; the Ft. Wayne Electric Company, by Mr. C. E. Searler, of Cincinnati, and the Crocker-Wheeler Company, by Hugh A. Brown, Cincinnati representative.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED APRIL 12, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., New York.]

756,211. PRECIPITATING METALS FROM SOLUTIONS; Charles Butters, Berkeley, Cal. App. filed Oct. 3, 1902. (See page 771.)

756,223. PROCESS OF TREATING LOW-GRADE ORES AND TAILINGS BY ELECTROLYSIS; Ernest Fahrig, Philadelphia, Pa. App. filed May 9, 1903. (See page 771.)

756,328. RECOVERY OF GOLD AND SILVER FROM CYANID SOLUTIONS; Samuel B. Christy, Berkeley, Cal. App. filed May 20, 1901. (See page 771.)

756,745. APPARATUS FOR ELECTRICALLY BLEACHING MATERIALS; August Alfred Vogelsang, Dresden, Germany. App. filed Sept. 21, 1904. (See page 772.)

756,813. LONG-DISTANCE TELEPHONE SYSTEM; Michael Beck, Minneapolis, Minn. App. filed Nov. 12, 1900. (See page 772.)

756,824. TELEPHONE SELECTING DEVICE; Lawrence E. Brock, Celina, Ohio. App. filed May 13, 1902. (See page 772.)

756,844. BRACKET BLOCK FOR CONDUIT MANHOLES; Guy M. Gest, Cincinnati, O. App. filed Dec. 13, 1902. A frame set into the wall contains a vertical slot in which the brackets supporting the cables have a sliding adjustment.

756,870. ELECTRIC RAILWAY SWITCH; Melbourne A. Marks, Jr., Brookline, Mass. App. filed Feb. 4, 1903. Details of a circuit closer applied to the trolley wire for directing the current into the solenoids that throw the switch point.

756,891. ROTATORY ELECTRIC TUBE-FURNACE; Henry Noel Potter, New Rochelle, N. Y. App. filed Nov. 21, 1901. (See page 771.)

756,941. SPARK GAP FOR ROENTGEN RAY APPARATUS; John T. H. Dempster, Schenectady, N. Y. App. filed June 18, 1898. The terminal balls are kept cool by mounting them upon rotating disks.

756,954. MAGNET COIL SPOOL; Henry Geisenhoner, Schenectady, N. Y. App. filed Sept. 13, 1902. The spool consists of a cylindrical body of sheet metal having end retaining devices formed out of corrugated metal strips.

756,957. ELECTRIC SAFETY SYSTEM FOR RAILWAYS; Jacob Hanna and Charles S. Gilman, Rivera, Cal. App. filed May 7, 1902. Details of a system wherein the brakes of the train can be actuated from the roadside when necessary.

756,959. TROLLEY CATCHER; Montgomery H. Johnson, Utica, N. Y. App. filed July 15, 1903. Details of a spring drum and pawl and ratchet device mounted upon the dashboard to control the cord.

756,960. ROTARY CONVERTER SYSTEM; Edward M. Hewlett, Schenectady, N. Y. App. filed July 24, 1899. A circuit breaker is controlled by any one of a number of rotary converters, an indicator showing which converter operates the circuit breaker.

756,966. PANEL BOARD FOR ELECTRIC DISTRIBUTION; George H. Jones, Chicago, Ill. App. filed Nov. 20, 1903. Means for readily altering the grouping of the different circuits to the meters so that each circuit may be metered individually or any number of circuits may be readily grouped under one meter.

756,976. PORTABLE TESTING AND COMPARING INSTRUMENT FOR ELECTRIC INCANDESCENT LAMPS; Albert McCandlish, George Lane, Bredbury, England. App. filed June 26, 1903. A box containing lamp receptacles for a standard lamp and a lamp to be tested and a meter, all conveniently arranged for testing.

756,979. HANDLE FOR ROTARY SNAP ELECTRIC SWITCHES; Charles G. Perkins, Hartford, Conn. App. filed Oct. 29, 1903. A spring supported handle which holds both the cover and the dial within the cover, in place.

756,980. ELECTRIC RAILWAY; William B. Potter, Schenectady, N. Y. App. filed July 5, 1902. A metallic cover for the third rail made in insulated sections so as to localize any escape of the current into the cover.

756,991. ELECTRIC CONDENSER; Matthew O. Troy, Lynn, Mass. App. filed July 19, 1902. When the sections of the condenser are placed in the supporting frame, their terminals engage with spring contacts carried by the frame.

756,999. OVERFLOW ALARM; Edward M. Weeks, Washington, D. C. App. filed Jan. 20, 1904. A ball float is mounted upon a special frame applicable to a tank and carrying circuit terminals to be engaged by the ball when the liquid reaches a certain level.

757,000. DEMAND METER; Roges S. White, Philadelphia, Pa. App. filed Aug. 15, 1903. A maximum demand meter having mechanism for actuating an indicator, a device responsive to current conditions for releasing the mechanism and means whereby the operation of the mechanism stores energy opposing the action of the releasing device and tending to stop the mechanism.

757,007. LAMP TERMINAL; Howard I. Wood and Ralph C. Robinson, Schenectady, N. Y. App. filed July 26, 1902. A special clamping device for holding the solid terminal in a mercury vapor tube lamp.

757,019. SYSTEM OF MOTOR CONTROL; Frank L. Butler, Schenectady, N. Y. App. filed Sept. 13, 1902. A motor controller comprising a number of separately actuated contacts, each operated by a pneumatic device, and a master controller comprising independent valves controlling said devices individually from a distance.

757,030. SIGNALLING APPARATUS; Ernest A. Faller, New York, N. Y. App. filed June 22, 1903. The employment of a distinct circuit for restarting the transmitter after each group of signals is sent and the employment of a different circuit for transmitting the signals, makes it possible to render continuous the alternate actuation of the receiving station and the transmitting station.

757,031. SEMI-AUTOMATIC TELEPHONE EXCHANGE; Ernest A. Faller, New York, N. Y. App. filed July 1, 1903. (See page 772.)

757,036. PROCESS OF PRODUCING CHEMICAL COMPOUNDS; John J. Griffin, Washington, D. C. App. filed Jan. 16, 1903. (See page 771.)

757,056. MEANS FOR PROTECTING ELECTRICAL MEASURING INSTRUMENTS; Maurice C. Rypinski, Schenectady, N. Y. App. filed July 25, 1901. A conductor of high resistance is normally in series with the instrument for protective purposes but can be shunted out while the readings are being taken.

757,070. RAIL BONDING CONSTRUCTION; Edward G. Thomas, Waltham, Mass. App. filed March 19, 1903. The terminals of the bond are located at extreme diagonal positions with respect to the abutting faces of the joint so that the amplitude of the expansions and contractions of the bond is lessened.

757,079. ELECTRIC ARC LAMP; James J. Wood, Fort Wayne, Ind. App. filed Sept. 4, 1903. Yieldingly supported parts are utilized to avoid the effect of vibrations in an alternating current lamp.

757,107. SAFETY DEVICE FOR ELECTRIC RAILWAY SYSTEMS; George Gibbs, New York, N. Y. App. filed Aug. 26, 1903. The circuit breakers in the feeders are caused to open under abnormal conditions by means of an auxiliary circuit, a terminal of which is arranged in proximity to the working conductor, so that current will be delivered to it in case of a derailment or similar accident.

757,125. ELECTRICAL RAILWAY DANGER SIGNAL; William E. Karns, Parkers Landing, Pa. App. filed Nov. 12, 1903. Signal-controlling circuit wires are stretched along localities where landslides are likely to take place, so that upon such an occurrence, the circuit will be broken and signals displayed.

757,138. THIRD RAIL FOR ELECTRIC RAILWAYS; Patrick T. McGowan, Avoca, Pa. App. filed Dec. 22, 1903. The rail has a brush-engaging surface at the side.

757,164. BATTERY-CELL; Emerson Whatman, Lynn, Mass. App. filed July 2, 1903. (See page 772.)

757,184. MEGAPLEX RELAY; Richard A. Engler, Dubuque, Iowa. App. filed July 13, 1902. (See page 772.)

757,185. MANUFACTURE OF CYANAMID SALTS; Georg Erlwein, Berlin, Germany. App. filed Aug. 16, 1902. (See page 771.)

757,191. DEVICE FOR PREVENTING RAILWAY COLLISIONS; Charles Holtmann and Joseph F. Butler, Pittsburg, Pa. App. filed March 5, 1903. Two trains on the same block will have their air-brakes operated automatically by current traversing the track from train to train and actuating electro-magnet apparatus on each train.

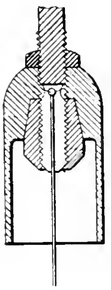
757,192. TIP OR TERMINAL FOR ELECTRIC WIRES; Stephen C. Houghton, San Francisco, Cal. App. filed Dec. 20, 1903. A pin having a hooked end for engaging the wire and a tube passing over the end of the pin and formed with a split ferrule.

757,203. PUSH BUTTON; Charles J. Klein, New York, N. Y. App. filed Nov. 14, 1902. Provision is made for clamping the wires of the circuit in a position where they will be engaged by the head of a circuit-closing plunger.

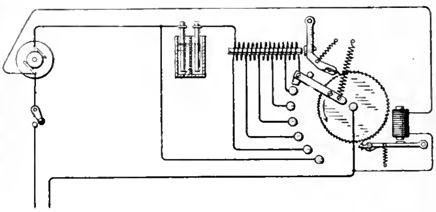
757,257. TELEPHONE-RECEIVER SUPPORT; James Alexander Brown, Warren, Ohio. App. filed Oct. 8, 1903. (See page 772.)

757,264. ELECTRIC RAILWAY; Davis J. Cable, Lima, O. App. filed March 11, 1903. Details of a mounting and covering of a third rail.

757,271. ELECTROMECHANICAL GONG; Frederick W. Cole, Newton, Mass. App. filed Oct. 4, 1902. Details.



757,302. ELECTRIC CURRENT REGULATOR; Newton Harrison, New York, N. Y. App. filed April 21, 1903. The counter-electromotive force or self-induction in a sectional coil is used instead of an ordinary resistance, as



757,007.—Lamp Terminal. 757,302.—Electric Current Regulator.

a starting device. The self-induction is caused by an interrupter in the circuit and the magnetism of the induction coil is utilized to operate a step by step device for cutting out the sections of the induction winding.

757,341. RELAY MAGNET; William Palmer, Jr., Rincon, Territory of New Mexico. App. filed June 14, 1902. Details.

757,346. ELECTRIC SIGNAL FOR RAILWAYS; William B. Ramsay, Hickory, N. C. App. filed May 29, 1903. Details.

757,355. GALVANIC BATTERY; Charles B. Schoenmehl, Waterbury, Conn. App. filed Nov. 22, 1899. (See page 772.)

757,357. DYNAMO BRUSH HOLDER; William Slee, St. Louis, Mo. App. filed Sept. 8, 1903. Details.

757,364. COMBINED LIGHTING AND ALARM DEVICE; John Thorsen, Chicago, Ill. App. filed Sept. 24, 1903. A spring motor is released by an electro-magnet to fire cartridges, turn on a light and ring a bell.

757,377. PRINTING TELEGRAPH RECEIVER; James D. White, London, England. App. filed Aug. 29, 1903. Improvements for increasing the range of characters without increasing the amount of the step by step movement of the mechanism, in that type of machine described in U. S. Patent 751,363.

757,388. LIGHTNING ARRESTER; Garrison Babcock, Chicago, Ill. App. filed Sept. 20, 1902. An insulated fusible strip is inserted between the plates so that when the fuse is melted, the insulation is carbonized and forms a conductor between the plates.

757,396. STORAGE-BATTERY GRID; George W. Frost, Columbus, Ohio. App. filed Feb. 9, 1904. (See page 772.)

757,405. BOOSTER APPARATUS; Lamar Lyndon, New York, N. Y. App. filed Aug. 21, 1902. The motor driving the booster has two field circuits, one of which is in series on the line while the other is provided with a switch for opening and closing it at will.

757,406. BOOSTER APPARATUS; Lamar Lyndon, New York, N. Y. App. filed Aug. 21, 1902. Two field circuits on the motor that drives the booster, are differentially wound and connect to the line in such a way that variations of current strength in the line will cause similar variations in one of the circuits and inverse variations in the other.

757,418. INSULATING AND SUSPENDING DEVICE; Joseph Sachs, Hartford, Conn. App. filed Jan. 5, 1903. Details of construction of an insulator.

757,422. DRY BATTERY; Alfred F. Swan, Bayonne, N. J., and Allen W. Rose, New York, N. Y. App. filed July 22, 1903. (See page 772.)

THE SCRAP HEAP.

An interesting note appeared in our columns not long since to the effect that some Jablochkoff lamps had just gone out of service in Calcutta, India, after being in use over twenty years. We doubt whether this record could be equalled in this country for lamps, whether of the make in question or any other. The Jablochkoff lamps in this country had a brief although not particularly inglorious career, and this Calcutta episode is but another proof of the reluctance of our British and European friends to compile a scrap heap as sedulously as we do.

The relative life of electrical apparatus is a subject that is not much discussed, although we fancy there is a great deal of apparatus in service which is still giving a good account of itself after prolonged years of operation. Many of the early street railway motors are in use, we believe, and one frequently encounters primeval lighting apparatus. It does not follow that a plant is "scrapped" when it is exchanged for one of later date, and in fact, our advertising pages frequently give evidence to the healthy and active state of the second-hand market. A curious exemplification of the rage for change may be found in the lawsuit recently settled in favor of the Electric Light Company at Davenport, Iowa, which, after using its direct-current plant for two or three years, was ordered on pain of cancellation of its franchise by the city council, to change over to the alternating current. The courts have now sustained it in its refusal to scrap its apparatus in such a hurry, but there is no doubt that the rapid advance of the art very often brings about, without suspicious compulsion like that just referred to, radical changes in electrical apparatus of all kinds. In fact, it may be questioned whether the life of a telegraph or telephone system is much longer than that of a lighting and railway plant, with the proviso that when the apparatus is scrapped this does not always mean that it is broken up or altogether loses its functions of utility. It is an interesting commentary upon the way in which old material can be worked up that a steel plant at Hamilton, Ont., makes the claim that it has worked over into new material the iron of the original Niagara Suspension Bridge, the iron of the original Victoria Tubular Bridge at Montreal, the hull of the famous old Atlantic liner, the *City of Rome*, and the iron framework of the famous steamship the *Great Eastern*. In like manner, much electrical apparatus is living again to-day in forms that sometimes would hardly be recognized by those who used it when it was first brought out many years ago. We have seen lately some "long-waisted" Edison dynamos that certainly go back to the beginnings of the incandescent art, and we are told that the original Siemens & Halske electric road material, shown at Paris in 1881, is still earning a humble livelihood on the banks of Lake Leman, somewhere in the vicinity of Chillon.

DESIGN OF INDUCTION MOTORS.

Elsewhere we print an article by Mr. Hobart on the design of induction motors, which in a sense is a continuation of his article on the choice of the rotor diameter which we printed in our issue of January 23 of this year. The papers of Messrs. Parshall and Hobart on the design of electric generators for direct current, which appeared several years ago in the English engineering press, showed the critical judgment of these distinguished engineers in the application of formulas and theories to the design of direct-current machines. Intimately connected with the method of calculation of the inductance of the coils under commutation in direct-current generators is Mr. Hobart's correction and amplification of Behrend's well-known formula for the dispersion coefficient, upon which are based the circle diagram, and, with it, the theory of calculation of motors and generators embodying the induction principle.

The working of an induction motor or of an induction generator depends, according to Behrend's theory, primarily on two factors: First, the current which the motor takes while running at synchronous speed; and, second, the current which the motor takes while standing still. These two magnitudes determine the characteristics, such as power factor, torque and slip, of the induction machine, acting either as generator or as motor. The determination of the no-load or magnetizing current is a comparatively simple matter, as it involves only the calculation of the line integral of magnetizing force for the magnetic circuit of the motor, and requiring no constants of leakage or dispersion. This, however, does not apply in regard to the calculation of the current at standstill, the magnitude of which depends altogether upon the leakage and dispersion of the motor. The theory of the induction machine shows that the magnetizing current and the current at standstill are connected by a simple mathematical relation containing a factor which we term by courtesy a "constant," dependent upon the design of the slots, the air-gap, the pole pitch, and the length of the core. Behrend maintains that the constant depends "upon a great many other conditions of which we are still profoundly ignorant," and it is Mr. Hobart's aim to throw light upon this question.

Mr. Hobart's results may be summarized by saying that he shows the dependence of the factor in Behrend's formula on the ratio of the length of the core to the pole pitch, the factor being smaller the greater this ratio, proving the accuracy of his curves by tests on a large number of induction motors. A critical contribution to the literature of designing is most valuable by fixing ideas and dispelling hazy and incorrect notions which lead to superficial judgment and sham knowledge. From the judgment of fact there is no appeal, and we are all indebted to Mr. Hobart for his laborious tables and data to check the assumption of theory.

THE DIFFERENTIAL TELEPHONE.

The last number of the *Physical Review* contains an interesting article by Messrs. Duane and Lory on the differential telephone. Of course, differential telephones have been used for many years in alternating-current laboratories, so that there is no novelty in the instrument itself; but the directions given, in the article, for adjusting the instrument, enable it to attain a much higher standard of sensibility and measurement than would otherwise be possible. In order that a differential telephone may be capable of giving accurate results, it must be wound with mechanical symmetry, the magnetizing actions of the two windings must be well nigh identical, the resistances of the two windings must be almost exactly equal, and their inductances must also be almost exactly equal. To effect these equalities is by no means so easy as it sounds, either verbally or telephonically. The writers claim, for a carefully adjusted differential telephone, a theoretically attainable degree of accuracy, under laboratory conditions, of one-hundredth of one per cent., in the measurement of small ironless inductances, and a practically attainable degree of accuracy of one-twentieth of one per cent., or less. It is very desirable that a research should be made with such an instrument upon the resistivity of electrolytic solutions, with different frequencies of alternating current, throughout a wide range, in order to ascertain what effect, if any, is exerted by the frequency, upon the measurements. It has been asserted that the frequency may have a very appreciable effect, but we know of no measurements yet forthcoming to demonstrate the fact.

ZOSSEN STEAM TRIALS.

The daily papers are printing dispatches of renewed tests on the now famous Zossen line, this time with steam locomotives of weird and fanciful design intended to show to all the world how the best traditions of German express service can be preserved in spite of the threatened irruption of electric motors. Full details of the slow degrees by which the speed was raised to limits hitherto unknown on German government railways are not yet forthcoming, but we presume the earlier trials to stiffen the nerves of the daring experimenters were on hand cars driven by brawny Teutons goaded to desperation by the knowledge that the nearest available beer was at Marienfelde. Be that as it may, a few days ago trial was made of a mighty locomotive weighing with its tender 85 whole tons and using superheated steam and lubricating oil in apparently about equal proportions. To this space-devouring and time-annihilating monster were hitched three German cars and with a loaf of schwartzbrodt chained to the safety valve, and the terrified officials stretched on the floors of the cars hanging on with hands and teeth to keep from rolling off, the whole outfit hurtled through the shuddering atmosphere at 84½ miles per hour! We have searched literature from the time of Cadmus on for a suitable pæan of triumph with which to celebrate this epoch-making achievement, but the only one which seems to fit the case is a sonorous classical fragment in which a mountain and a mouse are the principal figures. O, mighty prophetic soul of Æsop, how hast thy wisdom shone through the mists of centuries to illumine this latest victory of mankind!

The addition of three more cars pulled down and speed of this leviathan of the rails to a scant 80 miles per hour, and we hesitate to imagine what would have been the result of adding still three more. To our benighted American eyes the whole loudly heralded performance looks like M. 1.20. Hardly a summer day passes in which one of the regular trains between New York and Philadelphia does not run off miles in 45 seconds or thereabouts, and there is one record on the Lehigh Valley Railroad of more than 40 consecutive miles run at the rate of 80 miles per hour. There is, too, a run on the Burlington route of 14.8 miles in just 9 minutes—98.7 miles per hour, and of single miles in less than 40 seconds there have been too many to keep account of. And all this has been done without any fuss and feathers by standard express locomotives, for the most part drawing regular trains. There has been no solemn posing about it—a train chanced to be a bit late and the engineer, with a clear track ahead, has merely shaken out a few kinks and arrived on schedule time. In the trials of regular German express engines over the Zossen course none of them is reported as having touched 80 miles per hour even with a three-car train, much less with one of ordinary length. These trials may be amusing to the officials who draw up elaborately sealed reports upon them, and may be more or less interesting to the engine builders; but as demonstrations of the capabilities of steam locomotives they are about as convincing as a press report from Che-Foo. If the Boss of the German railway system (we forget his polysyllabic official title) really wants to chase a few speed records, he had better import a Yankee track boss and a few of our standard engines and get down to business. They can show him more about making time in a week than he will learn at Zossen in a month of Sundays. We have the highest respect for German engineering skill in general, but in the steam railway business it seems to be hopelessly behind the game just at present. And if America as a school of instruction is too distant our Teutonic friends might organize a secret service to pry into the details of the express service of their Gallic neighbors, who in railroading vastly outrank other continental countries, and can give us also a run for our money.

As a mere feat in railroading it is not a difficult matter under favorable conditions to make one or a few miles at a speed of 100 miles per hour or thereabouts. But so long as the locomotive has to be burdened by carrying its own fuel and water and carrying also a large dead weight not directly concerned with power production, its power of sustained high speed is necessarily limited. The strong point of the electric locomotive is that it is not compelled to carry its power station upon its back, but can utilize nearly the full weight necessary for adhesion to the rails for available driving power. Nor is it forced to slow down for taking on fuel or to scoop up water, or to get the fire in condition. It can attend strictly to the business of pulling, first, last and all the time. It can hold the same speed for a long run as for a short one, so long as the track is in good condition. The difficulty with greatly increased running speeds is not in the electrical part of the equipment, but with the track; and more than all else, with the commercial demand for high speed. Conditions of equipment being the same, there is more profit in moderate speed than in very high speed, and so long as there is only nominal competition between railroads there will be no radical improvements in speed. It is only in long runs that very high-speed trains show to the best advantage, which is another obstacle, since the equipment of five hundred or a thousand miles of track for hundred-mile-an-hour work means a very large investment, right of way difficult to be obtained, the abolition of all grade crossings, and fierce opposition from the existing lines threatened. Some day a horoscope favorable in all these points can be cast and then the thing will be accomplished. It is strictly an electrical job, however, and the continuance of these trials at Zossen will only serve to emphasize the fact. They display admirable zeal, but they lead up a blind alley.

The Measurement of Stray Power by Calorimetry.

In the operation of water-cooled transformers, the power wasted in the iron and copper may be determined both electrically and thermally. In fact, while the electric method is commonly regarded as the simpler and more reliable, the thermal method is often employed in addition, as a check. All that requires to be done is to turn on a steady stream of cooling water, and, after a sufficient lapse of time for arriving at a substantially steady thermal condition, to measure the rate of flow of water, together with the difference of temperature between the incoming and outgoing stream. This heat delivery, expressed in watts, corresponds to the power wasted in the transformer. In a paper by Prof. Threlfall, appearing in the last number of the *Journal* of the Institution of Electrical Engineers (London), the same method is described as applied to tests of alternators running in air, the heat delivery in this case being measured in the flow of air circulated by a ventilating fan. A light housing is built over and around the alternator to be tested, so as to enclose the stream of ventilating air. A steady load is applied to the alternator, the power being delivered by the shaft passing through the wall of the housing. After a sufficient lapse of time, depending upon the size of the machine, the rate of flow of air driven through the system is measured, as well as the difference of temperature between the incoming and outgoing air. The flow of heat thus determined, as expressed in watts, measures the power wasted electrically in the copper and iron of the alternator; also the power wasted in windage friction, as well as a considerable part of that expended in bearing friction.

Much more care has to be taken in the measurement of the rate of air-flow in this test than in the rate of water-flow in the corresponding test of water-cooled apparatus, partly because air is a readily compressible fluid, and partly because its thermal capacity is much less than that of water. It takes about 4 joules to raise a gram of water 1° C. (more nearly 4.18). It takes about 1 joule to raise a gram of air 1° C. (0.993 joule). Consequently, by mass, air has only one-quarter of the thermal capacity of water. Moreover, since a gram of dry air at standard temperature and pressure occupies approximately 773 c.c., 1 c.c. of standard air only carries off 1/773 joule in rising 1° C. Consequently, by volume, standard water has about 3,250 times the thermal capacity of standard air, and 3,250 times more volume of standard air must be sent through an apparatus to carry off the heat for a given temperature elevation, than in the corresponding case with water.

The rate of flow of water cooling a large transformer is usually only a few cubic centimeters per second; but the rate of flow of air supplied by a ventilating fan to an alternator of moderate size, in these tests, is measured in cubic meters per second. In order to measure the rate of flow of air through a delivery pipe 21 in. in internal diameter, a Pitot tube was used. This is a well-known simple form of pressure gauge, consisting of a small cup supported in the delivery pipe so as to face the air-stream, and having a small tube leading from the bottom of the cup to a pressure gauge outside. It is shown very interestingly in the paper that with proper precautions, the pressure indications of a Pitot tube are capable of determining with considerable accuracy the velocity of the air-stream in the neighborhood. The effect of friction at the walls of the delivery pipe materially reduces the velocity of air-flow at and near the walls. A correction of about 6½ per cent. has to be made for this effect on the velocity of flow as measured at the center of the pipe. Corrections have also to be made for barometer, hygrometer and mean temperature of the air. It is claimed, however, that after all corrections are made, the method is capable of measuring power losses within a few per cent., and efficiencies within a fraction of one per cent. The advantage of the method seems to be that the apparatus required is comparatively inexpensive, and that it may be employed when no other measure of frictional losses is available. The disadvantages of the method are that it requires a special housing to be built over the machine to be tested, that the load must be kept steadily applied to the machine for several hours, and that many corrections have to be taken into account in the computations.

It does not seem likely, therefore, that this method of testing will come into general use. The ordinary electrical methods for measuring stray losss are so much simpler and swifter that there is no comparison between them and the calorimetric method. It is true that some of the assumptions involved in these electrical stray-loss methods are open to dispute, in regard to accuracy under full-load conditions. Nevertheless, if machines are specified to possess a certain efficiency, when tested by the electrical stray-loss method, the results are at least, comparable with those of other machines tested in like manner. The main value of the paper seems not merely to reside in the working out of a feasible method of measuring the efficiency of alternators, but also in supplying much valuable information concerning the flow of air through straight tubes. It is well known that this is a subject on which much difference of opinion exists, and where empiricism is rampant. In showing how to obtain accurate results from a Pitot tube, the author has contributed much to this subject, quite independently of other considerations. This is one more instance of the indebtedness of engineering to physics. In the discussion on the paper, the theory of the Pitot tube was developed very clearly, showing that the velocity near the cup was the square root of twice the density times the difference of pressure between that at bottom of the cup and at the side walls of the flue. It was also shown why the cup must have thin edges and squarely face the direction of flow; while the pressure at the walls must be found with a very flat-mouthed exit tube.

The Union Engineering Building.

The preliminary work of the Conference Committee on the Union Engineering Building was closed last week after a considerable amount of labor on the part of all interested, and the programme of competition will be placed in the hands of architects during the present week. In this work the committee has enjoyed the advice of Prof. W. R. Ware as professional adviser, and it is needless to say that the programme has been drawn with great care. The plans submitted in the competition by the selected architects and by those who enter the open competition are to be in the hands of Prof. F. R. Hutton, secretary of the committee, by June 15, and it is expected shortly thereafter to arrive at a decision as to the preferable plan. The Engineering Building on Thirty-ninth Street, about midway on the north side of the block, will occupy about 10,500 square feet, exclusive of the 15 feet open space reserved under the city ordinances, the outside dimensions of the land being about 125 feet by 100 feet. To the east of the building Mr. Carnegie has bought and reserved a residence which will be maintained at its present elevation so as to protect the air and light of the building on that side. The general plans of the building have already been outlined in these columns, but it may be stated that there will be at the top of the building three stories held for the use of technical societies invited to participate in the benefits of the building. Three other similar floors will be reserved, one each for the American Institute of Electrical Engineers, the American Institute of Mining Engineers and the American Society of Mechanical Engineers. These floors will make ample provision for offices and each will have a large, handsome reception room as well as board and committee rooms. Below these will come the library, virtually a double floor; although the committee will entertain plans placing the library at the top of the building. Next below will come a large main auditorium floor, which will seat from 1,200 to 1,500 people, with 1,000 on the floor and about half as many additional in the galleries. This floor will preferably be as near the sidewalk as possible, and may have above it or below it a number of smaller meeting rooms having similar purposes, seating audiences of from 500 down to 100. There will be six such rooms and these as well as the large room will all be thoroughly equipped with gas, compressed air, steam, water, electricity, etc., for the conduct of experiments and demonstrations. There will also be lounging and smoking rooms, and provision will also be made for special banquets by outside caterers and the serving of occasional collations. The floor on the street level will be appropriated mainly to administrative purposes with three coat rooms capable of taking care of 1,500 garments at once, a ladies' dressing-room, a bureau of information, public telephone and telegraph offices, the post-office and sales department and shipping and receiving offices for books, publications, etc. Below this floor, from which probably a fine stairway will lead to the auditorium above, will come the basement and sub-basement, with provision for storage purposes, machinery, coal and operative apparatus. There will be three elevators in the building of large capacity, one being able to take care of freight. The library floor will be laid out so as to accommodate not only the present consolidated libraries of 50,000 volumes, but a well-rounded comprehensive collection of six or eight times that number. There will also be a number of reading and reference rooms on that floor. For the purposes of the Engineering Building and the Engineers' Club regarded as separate structures, it is proposed to expend about $1,000,000, leaving the other $500,000 for tearing down of old buildings, excavation, architects' and engineers' fees, machinery, elevators, lighting fixtures and the equipment of the library and auditorium. As to the architecture of both buildings, it is the expressed wish of Mr. Carnegie that it should be simple and dignified, something that will be as good in style a hundred years from to-day as now.

The Engineers' Club, with a frontage of 50 feet and a depth of 100, will front on Fortieth Street and Bryant Park, looking across to the New York Public Library, now partially completed. It is proposed that the club building shall be eleven and a half stories, including also basement and sub-basement, but differing, of course, in all other respects from its near neighbor. The half story will be on the roof and will have the kitchen and some rooms for accommodation of the help, the other part constituting a roof garden with outlook on the little park and Hudson River. The eleventh floor below will be occupied entirely by the main dining-room or banquet hall and its service facilities, and will be one of the finest rooms in the house, looking across to the Park and New York Library. Below this will come the breakfast room floor with a large breakfast and lunch room and several private dining-rooms. Next will come four floors, occupied by bedrooms for members. There will be sixty of these rooms in all and the smallest is to be not less than 150 square feet. There will be generous bath facilities and all rooms will have outside air and light. Below these sleeping accommodations will come the billiard room floor, with a large billiard room across the front of the house and with board rooms, committee rooms, card rooms, etc., in the rear. Next below will come the floor containing the club room or general reception and meeting-room in front and the library in the rear, these being the only two rooms on that floor. The next or ground floor, raised several feet above the sidewalk, will contain the office, large coat rooms, general reception rooms, telephone booths and a large, handsome café. Below the sidewalk will be a basement and sub-basement containing machinery, refrigerating plant, store rooms, wine cellar, steward's rooms and sundry other facilities. There will be three elevators running from cellar to roof, one with capacity for freight. There will also be a main grand ornamental stairway running up to the level of the billiard room floor and there will be service stairways throughout, which can also be used by the members. It is believed that good architectural plans will enable the buildings to present from the Bryant Park front a harmonious and handsome ensemble above the roofs of the private dwellings in the vicinity. A covered areaway across the light well between the two buildings will render intercommunication easy and the committee will also entertain plans throwing a light, artistic bridge across at about the level of the library floor of the Engineering Building.

The six architects selected for the mixed competition have already been named in these columns, and this week the printed programme will be placed in their hands and will also be available for other architects in good standing, many of whom wish to come into the open competition. The selected architects are each to receive $1,000, which is to be charged against the commissions in case of success. The competitors on the open list have the encouragement of four equal prizes of $200 each for the four best designs. The date for the filing of the competitive plans is June 15. The committee hopes to be able thereafter to make a prompt decision and will proceed with the prosecution of the work without delay.

The three societies have been requested recently to appoint members to serve on a special committee which shall at once take the work in hand of unifying and harmonizing the methods of their various libraries, so that when the collections are brought together, they will be ready for co-operative administration.

Telegraphers in the Civil War.

As is well-known, the United States Corps of Military Telegraphers after many years of work, has at last succeeded in securing recognition of the services of the men who worked the key at the front in the Civil War. In a report favoring the extension of pension privilege to the operators who thus served the government, Senator Scott, of West Virginia, has related some interesting incidents of the service which enabled the armies and parts of armies to keep in communication with each other, and which enabled President Lincoln to be in touch with all his generals. Throughout the war there were, all told, 15,000 miles of wire operated by the army telegraphers, and the service cost the government about $3,000,000. Twelve hundred operators were employed.

During the operations in front of Atlanta, in 1864, twenty miles of wire was kept in operation twenty-eight days by almost as many operators, half of whom were exposed to the enemy's fire while at work at their instruments. At New Orleans, says the report, the operators and linemen were not only in danger of being shot, but risked their lives almost daily in the surf in trying to keep the submarine part of their system in working order. The active service of the operators practically came to an end when they rushed a line of wire to Appomattox, over which the news of Lee's surrender was received at Washington within two hours after the event.

President Wilson, of the Society of the United States Military Corps, says of the military telegraphers of the Civil War: "The list of casualties and captures in this little corps, probably aggregating 322, establishes its military character. The 15,389 miles of military telegraph lines constructed and operated in the threatres of the war by this corps, hundreds of whom were within range of the enemy's guns and often under fire, evidences a devotion and bravery that surely make its members worthy of comradeship with others of the army."

The Plant of the Kansas City Home Telephone Company.

By Max Loewenthal, E.E.

THE marvelous development of the electrical industries throughout the United States during the past decade contains no record that can excel the growth of the independent telephone movement. The latest statistics show that of the 212 cities in the United States having more than 20,000 inhabitants, 162 already have independent telephone exchanges, franchises have been granted in 11 additional and applications are pending for franchises in 12 more. There are at present in operation in the United States over 6,000 independent telephone exchanges which operate in round numbers 2,000,000 telephones in exchange service, representing an investment of over $200,000,000. It is interesting to note in this connection that only 4 per cent. of the population of this country are using telephones, while in some sections it is being used by from 12 to 15 per cent. of the population and even more. The education of the general public to the use of the telephone as a convenience has developed its use to an absolute necessity. The independent telephone development in Missouri and Kansas has been so rapid and popular that there are to-day twenty telephones in operation where there was one at the beginning of the movement. All of the independent exchanges in this territory are being rapidly connected by long-distance service.

One of the most perfect types of the modern telephone system is that which has just been completed by the Kansas City Home Telephone Company, in Kansas City, Mo., and Kansas City, Kan., this system having immediate facilities for taking care of 8,200 subscribers, and an ultimate capacity of 34,000. The system will have in operation before the end of the year 1904 about 8,500 private line telephones and has now in successful operation about 6,000 lines, installing new telephones at the rate of twenty a day.

The Kansas City Home Telephone Company was incorporated in November with a capital of $50,000, which was increased in January, 1903, to $3,000,000, of which $1,700,000 have been issued. The balance of the stock and bonds, there being a bonded indebtedness of $1,700,000, is in the treasury for future extensions and betterments. The company operates under a thirty-year franchise

FIG. 1.—MAIN EXCHANGE BUILDING, KANSAS CITY, MO.

in Kansas City, Mo., and a twenty-year franchise in Kansas City, Kan., the two cities having a combined population of about 300,000.

The movement which led to the organization of this company was started about two years ago. The franchise which was originally granted to John Enoch was purchased by the Central Telephone Construction Company, of Toledo, Ohio, which constructed the entire plant. The officers of this company are Ed. L. Barber, president, O. C. Snider, secretary and treasurer, and James S. Braley, Jr., manager. Through the efforts of this company the enterprise was financed by the organization of an underwriting syndicate, managed by the Germania Trust Company, of St. Louis, now a part of the Commonwealth Trust Company. The construction company also had entire charge of the canvass for subscribers and secured 9,000 three-year contracts with comparatively little effort.

Actual work was started in the fall of 1902. Multiple-duct con-

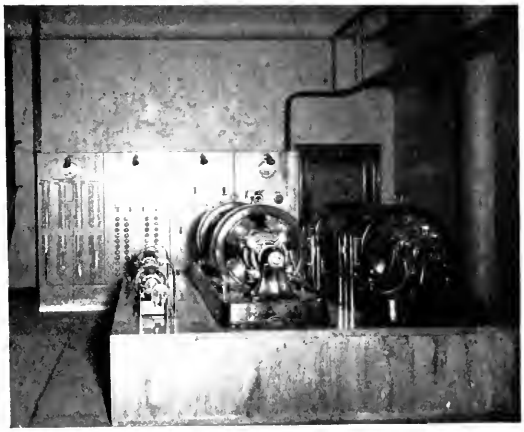

FIG. 2.—POWER PLANT, MAIN EXCHANGE.

duits were laid throughout the entire business section and the company owns at present 750,000 duct-feet of conduit and 260 manholes. All-copper overhead construction has been adopted throughout the residence districts and local distributing poles are located in the alleys throughout the city. So as to distribute efficiently the load on the system it was decided to build one main and three branch exchanges, each serving the section within which it is located. The main exchange building, shown in Fig. 1, is a handsome three-story and basement brick building, with terra cotta trimmings, and is located on Baltimore Avenue, in the very heart of the business district of Kansas City. It is 120 ft. in length and has a frontage of 60 ft., while its width in the rear is but 44 ft., about 8 ft. having been cut off on each side so as to insure ample air and light shafts,

FIG. 3.—MAIN, INTERMEDIATE AND RELAY RACKS, MAIN EXCHANGE.

should buildings be erected on either side of the exchange. The 37 lead-covered cables, each consisting of 200 pairs of No. 19 gauge Roebling dry-core paper-covered wires, enter the building in the basement, where they have been spliced to twice the number of 100-pair cables, which run to the main distributing frame on the floor above.

In the basement also are located the repair and carpenter shops, benches, lockers and [illegible] the outside men, hot water and steam combination boiler and the material room.

On the second floor are the power and distributing frame room, the long-distance tollboard, the kitchen, dining-room, toilets and lockers for the operators. The power plant, shown in Fig. 2, consists of a duplicate set of motor-generators of the Holtzer-Cabot type, for charging purposes, the motor end receiving 114 amp. at 220 volts at a speed of 1,000 r.p.m and the dynamo generating 300 amp. at 60 volts. As there is a duplicate set of batteries, the charging machines are so connected through the switchboard that either set of batteries may be charged by either machine, and the machines are so wound that the batteries may be charged while furnishing current for the exchange without creating noise in any of the talking circuits. They are of sufficient size for the ultimate capacity of the exchange.

The ringing machines, made by Roth Bros. & Co., are equipped with a device for the "busy back" signal for the trunking positions, and for signalling to any subscriber who may have left his receiver off the hook. The generators each have a sufficient output to operate the entire capacity of the switchboard.

The power switchboard, also seen in Fig. 2, consists of four panels, known as the fuse, ringing and two power panels. The board is of Tennessee marble, is 12 ft. long and 8 ft. high. The power panels are provided with Weston voltmeters and ammeters and necessary switches for connecting either machine to the battery or for charging the battery and feed current to the switchboard. Automatic circuit-breakers prevent the current from flowing back from the storage batteries to the generators. The voltage of each individual cell may be read on a special low-reading voltmeter. All circuits leading from the power board are individually fused on the face of the board.

Toward the front of the building in the same room are the main and intermediate distributing and relay racks, shown in Fig. 3. The main racks are built up of structural iron and so braced as to be rigid and substantial. The main rack is provided with terminal

FIG. 4.—BATTERY PLANT IN MAIN EXCHANGE.

clips mounted on hard rubber and is arranged at present for 5,500 lines, but is so designed that it can be extended from time to time until the ultimate capacity of the exchange is reached. It affords the best facilities for the placing and removal of jumper wires.

The intermediate distributing rack, similar in construction to the main rack, is so arranged that any line may be connected to any operator's position without changing the number of the outside line, or the multiple jack. Adjoining this rack is the relay frame on which the line relays are mounted. Sufficient room has been left between the frames and the power plant to provide for the extension of the racks to such an extent as to permit of an ultimate room capacity of 12,000 subscribers.

The duplicate set of batteries is located in a room back of the power board. These batteries (Fig. 4) furnish all the current required for the operation of the exchange and are of sufficient capacity to operate the plant without recharging for 48 hours. Each set of batteries consists of 20 cells and the plates in each cell are placed in lead-lined tanks of such size that additional plates can be added until there are a sufficient number to operate the ultimate capacity of the exchange for 36 hours without recharging the cells.

In close proximity to the power plant is the desk of the wire chief. It is arranged for two positions and each position is equipped with 10 complete cord circuits with listening and ringing keys and 10 order wire keys. Space is provided in each position for an ultimate capacity of 40 line lamps and jacks, the present equipment being for 30 lines, operating automatically on lines leading, one to the monitor's and chief operator's desk, one to the trouble clerk and six to the strip of multiple jacks in the main board. Five jacks terminate in cords and plugs in the keyboard of what is known as the eleventh

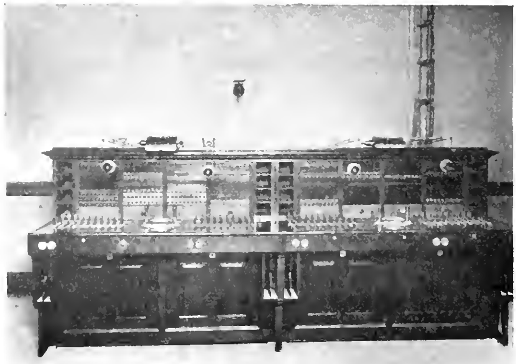

FIG. 5.—LONG-DISTANCE SWITCHBOARD, MAIN EXCHANGE.

and twelfth positions, two in cords and plugs at one of the trunking positions in branch exchange A, two in B and two similarly in branch C. There are five two-way leads which lead to the distributing frames in the various exchanges. All lines are duplicated in the two positions, so that they may be answered or tests made from either or both positions. A double-scale Weston voltmeter is situated between the two positions. All circuits are so arranged and designed that by manipulating the keys all required tests for "opens," grounds, reserves, shorts and all other trouble, both on the line and on the switchboard, can be made from this desk. The desk is also equipped with a key and special apparatus for signalling a subscriber when his receiver is left off the hook. A large number of pigeon-holes for trouble tickets are also provided. In a room adjoining the one described above the long-distance switchboard is located. This board, shown in Fig. 5, is designed for four positions and at present has a 30-line equipment. It is provided with modern incoming and outgoing trunking facilities for the rapid handling of service. The board is equipped with standard calculagraphs for the timing and checking of messages.

On this floor also, separated from the mechanical department by the main hall, is the dining-room for the operators, the kitchen, etc., and the offices of the superintendent of equipment. The main operating room, shown in Fig. 6, is situated on the top floor of the building and embodies every feature tending to mechanical and sanitary perfection. Plenty of light is insured by a large number of windows and artistic skylights, while forced circulation keeps the air pure, a 30-in. ventilating fan pulling the vitiated air out at the floor line.

The full common battery multiple switchboard consists of 19 sections of three operators' positions each. It has a present equipment of 5,500 lines with 160 outgoing trunk lines and 20 desk lines, also 150 incoming trunk lines and 16 desk trunks. Provision has been made in the construction of the board for an ultimate capacity of 12,000 lines, 360 outgoing trunks and 20 desk lines in each section, and 140 answering jacks and lamps in each position. Each of the local, trunk and desk lines is multiplied throughout every section. Each position is equipped with 15 complete cord circuits with listening and ringing keys, supervisory and pilot lamps and a bank of ten order keys.

The framework of the switchboard is built of structural iron. The exposed cabinet work, including all cable boxing in the exchange room, is made of selected mahogany. The rear of the board is enclosed with hardwood doors, which are readily removable. Each operator's position is provided with two pilot lamps, with jeweled caps mounted directly behind the cords and plugs, and just below the answering jacks. One lamp is provided with a white jewel and

FIG. 7.—EAST BRANCH EXCHANGE.

operates in circuit with the line lamp relay and remains lighted until the call is answered. The other lamp is provided with a red jewel and operates in circuit with the answering supervisory relay, and

be operated when either lamp is lighted. All supervisory and line relays are capable of being operated by a telephone through 1,200 ohms line resistance and can withstand twice the normal pressure of the battery without sticking.

All circuits are strictly metallic and perfectly balanced under all operating conditions and arranged so as to produce no cross-talking or other inductive disturbances. In the center of the main operating room, which measures 90 x 40 ft., are the desks of the chief operator, the trouble and information clerks, and all within full view of the entire board.

To the one side of the operating room toward the front of the building is the emergency hospital, equipped with all modern medical appliances for the temporary treatment of operators who may

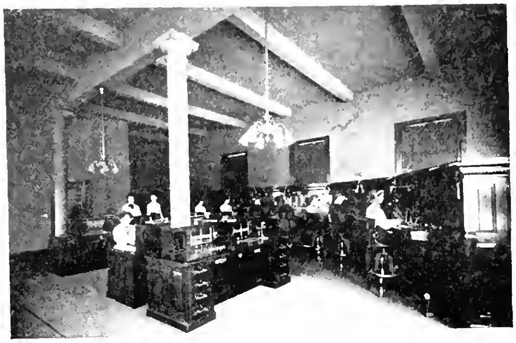

FIG. 8.—MAIN OPERATING ROOM, EAST BRANCH EXCHANGE.

be taken ill suddenly. To the other side is the operator's rest room, which is comfortably furnished and greatly relished by the operators during the two periods of rest of half an hour's duration. A well-

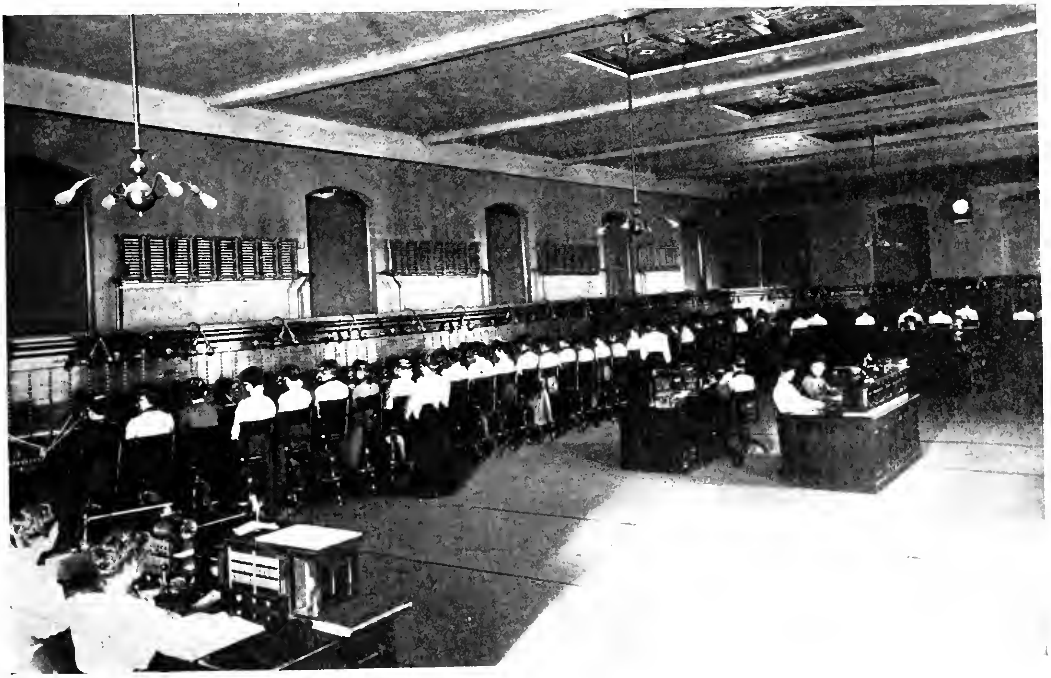

FIG. 6.—MAIN EXCHANGE OPERATING ROOM, KANSAS CITY, MO.

remains lighted until the connection is taken down, after the subscriber who originated the call has restored his receiver to the hook. Both pilot lamps are so connected that a night bell or buzzer may

known authority on the training of telephone operators (Mrs. H. Brown) is in charge of the operators, looking after their comfort and maintaining the strictest discipline, which is the foundation of good service and success. On the first floor of the building are the various offices, auditing and engineering departments and the meeting room of the board of directors.

The three branch exchanges of the company are almost identical in construction and equipment, one of the buildings being shown in Fig. 7. Branch exchange A, known as the East office exchange, is located in the eastern residence portion of Kansas City, Mo. Figs. 8, 9 and 10 illustrate the equipment of this and the other branch exchanges. The east switchboard consists of seven sections of three operators' positions each. It has a present equipment of 1,200 lines, with 120 desk lines, also 100 incoming trunk and 12 desk lines. Provision has been made for an ultimate capacity of 7,200 main lines.

FIG. 9.—MAIN AND INTERMEDIATE DISTRIBUTING AND RELAY RACKS, EAST BRANCH EXCHANGE.

Branch exchange B, known as the South office, is located in the southern residence portion of Kansas City, Mo. The switchboard in this exchange consists of five sections of three operators' positions each, and the present equipment consits of 700 lines, with 80 outgoing trunk and 20 desk lines and 75 incoming trunk lines and 9 desk trunks. Branch exchange C, known as the West office, is located in the business district of Kansas City, Kan. The board at this exchange is at present equipped for 800 lines with 60 outgoing trunk and 20 desk lines and 75 incoming trunk lines and 9 desk trunks. The entire equipment of the exchanges was furnished by the Stromberg-Carlson Telephone Manufacturing Company, of Chicago and Rochester, and the plants were built by the Central Telephone Construction Company, of Toledo, under the personal supervision of the chief engineer of the Kansas City Home Telephone Company, Mr. W. C. Polk.

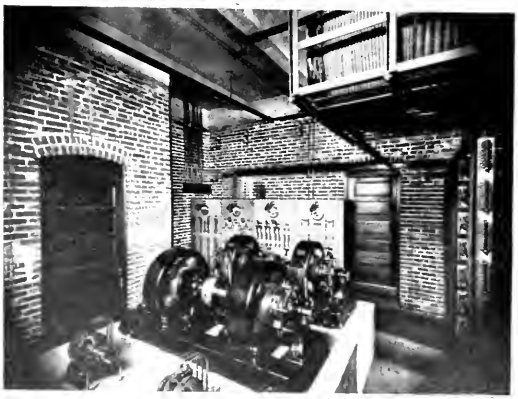

FIG. 10—POWER PLANT, EAST BRANCH EXCHANGE.

It may be of interest to note that the rates fixed by the ordinance in Kansas City, Mo., are $54 for business telephones and $36 for residence telephones, until January 1, 1907, when the company has the privilege of increasing the business rate to $60 per year. In Kansas City, Kan., the business rates are $54 and the residence rates $48 within a radius of 2½ miles from the business district, and the company is entitled to charge an additional $6 per mile per instrument for each additional mile or fraction thereof for extensions beyond this radius. The company has, however, adopted a uniform business rate in both cities of $54 and $36 for residence telephones, furnishing unlimited service between the two cities.

There are under construction and soon to be completed, long-distance lines reaching to Leavenworth and Atchison, Kan., and St. Joseph, Lexington and Sedalia, Mo. These lines will reach all independent telephone systems in their territory, and at their terminals connect with other lines reaching all over the States of Kansas, Missouri, Iowa, Illinois, Indiana, Kentucky, Indian Territory and Northern Texas. A line to Topeka, Kan., is now in service.

The officers of the company are: J. J. Heim, president; Henry Koehler, Jr., first vice-president; O. C. Snider, second vice-president, treasurer and general manager, and Hugh C. Ward, secretary. The directors of the company are: J. J. Heim, O. C. Snider, Hugh C. Ward, Walter S. Dickey and J. J. Swofford, of Kansas City; Max Koehler, Henry Koehler, Jr., Lee Benoist and A. W. Lambert, of St. Louis; Ed. L. Barber, of Wauseon, Ohio; James S. Brailey, Jr., of Toledo, Ohio, and Arnold Kahlman, of St. Paul. The officers of the long-distance company, known as the Western Independent Telephone Company, with an authorized capital of $1,500,000, are: Ed. L. Barber, president; J. J. Heim, vice-president, and O. C. Snider, secretary and treasurer.

Rocky Mountain Bell Telephone System.

The Rocky Mountain Bell Telephone Company, which has its headquarters at Salt Lake City, Utah, operates over the largest territory of any telephone company in the United States, and there are many interesting features connected with its rapid growth of the last few years. The toll line system covers the States of Utah, Idaho, Montana and Wyoming, the total area of which is 409,465 square miles. This area is larger by 90,000 miles than the Pacific Coast States, in which the Pacific States Telephone Company operates, and by way of comparison is 10,000 miles larger than the combined area of all the States lying south of Mason and Dixon's line, and between the Atlantic Ocean and the Mississippi River. This vast territory of the Rocky Mountain Bell Telephone Company is quite sparsely settled except in a few spots, where fertile valleys and mining camps have created cities and well-settled communities. In these four States the company has 6,000 miles of pole lines, with 16,000 miles of circuits, practically all of which are copper. The greatest stretch of connected lines is from the Wyoming-Colorado State boundary to the Washington-Idaho State boundary—a distance of 1,201 miles. The total number of subscribers of the company, including the city subscribers, was 19,000 in January and there were 96 exchanges in operation and 700 towns connected. During the last year 800 miles of new pole line were constructed, while the year's total growth of the company's system over the previous year was 39 per cent., a remarkable growth, but one which is entirely commensurate with the rapid development of the States of the Northwest.

The largest exchange is in Salt Lake City, where the company had 5,300 subscribers in January, an increase of 46 per cent. over the previous year. Butte has the next largest exchange with 1,800 subscribers, and Ogden comes next with 1,400 subscribers. Other good-sized exchanges are located at Provo and Logan, Utah; Pocatello and Boise, Idaho; Helena, Mont; Cheyenne and Laramie, Wyo.

At Salt Lake City during the last year the company has been engaged in putting its wires underground in the business district, and extending the conduit into the residence districts. At the present time there are over seven miles of conduit in the city. Electrolysis-proof paper conduit is used, it being laid in concrete in 8-ft. lengths. About 4,000 ft. of similar underground work has been done at Ogden. Other work of the year includes the erection of a new building in Cheyenne and the improvement of other buildings.

The toll-line system connects with the lines of the Colorado Telephone Company at Cheyenne and with the Pacific States Telephone system at Spokane, Wash.; Lewiston, Idaho, and Huntington, Ore., all three points being close to the western boundary of Idaho. A proposed connection with the Pacific States Telephone system through Nevada will follow the line of the Southern Pacific Railroad around the north end of Great Salt Lake. Still another connection with the Pacific Coast system is proposed through the southwestern portion of Utah, following the general line of the San Pedro, Los Angeles & Salt Lake Railway, which is now nearing completion. A connection with the lines of the Colorado Telephone Company is proposed at Grand Junction in the western part of Colorado.

The company's toll service is very good, that between Salt Lake City and Denver being of special excellence, when the distance, 800 miles, is considered. On this line the company operates through eight exchanges. Knife switches are used as cut-outs, thus giving a practically clean line, the drops being bridged in through 5,000-ohm resistances. The company has six circuits running north of Salt Lake City and five south.

In Salt Lake City, Ogden, Butte and Boise common-battery exchange systems are installed and common battery is used for calling in 16 other stations. Party lines are limited to four parties on one circuit for city subscribers, which adds greatly to the general quality of the service. In subscribers and rural districts 10-party lines are allowed.

The company has had a very satisfactory growth in these party lines in rural communities. One striking example is the Snake River Valley in Idaho, where a district about 10 miles wide and extending for 100 miles along the Snake River has been the scene of a wonderful development in rural telephones. That section with good irrigation and a fertile soil has been rapidly settled and practically every farm the entire length of the valley is now connected with the outside world by means of 10-party telephone lines, No. 9 B. B. Galvanized-iron wire is used with 2,500-ohm bells and $2 a month is charged for the service, the farmers erecting and owning the poles and lines.

The Rocky Mountain Company as yet has not met severe competition and in several instances has added to its system by the purchase of isolated independent plants. Competing companies are now operating at Boise, Idaho; Billings, Mont., and Salt Lake City.

As in the case of the Colorado Telephone Company, whose system was described in the ELECTRICAL WORLD AND ENGINEER in August, 1903, the Rocky Mountain company has to operate and maintain its toll lines through some wild and rugged mountainous country. Some of the greatest trouble it has had, however, has been occasioned by fires and storms in the timber districts. On the line between Missoula, Mont., and Spokane, Wash., the company has had a gang of men at work ever since it was built four years ago, cutting the timber down on both sides of the line. As one expedient to avoid the breaking of the line in case of trees falling across it, the wires were hung underneath the cross arms, so that the line would be carried to the ground in case of storms and still remain in operating condition. Another point at which great trouble has been experienced is the Fourth of July Cañon in Idaho, where for 25 miles the line is frequently put out of service by falling timber, deep snow, heavy winds or floods. The Rocky Mountain Bell Telephone Company is under the energetic and progressive management of Mr. David S. Murray.

Electric Trolleys in Peru.

The first electric railway in Peru was formally opened to the public at Lima, February 17, with ample ceremony and great rejoicing by the populace. The road connects Miraflores, Baranco and Chorillos, summer resorts, with Lima, and is 23 miles long. It really was built in record time. The company applied to the government for a charter to build the road December 9, 1902; the concession was granted January 20, 1903; work began June 11, of that year; the road was completed January 18, 1904, and inaugurated February 17. President Manuel Candamo, of the Peruvian Republic, who is the formal sponsor of the road, replied to the address delivered by its president, Jose Payan, and Archbishop of Lima, Manuel Tovar, invoked divine aid and pronounced the benediction upon the new enterprise. Manuel T. Marca, chief engineer of the city railroads of Lima, is engineer for the new road. W. McLimont is electrical engineer, and Emilio Godoy, manager. The cars and electric plant are of American manufacture.

A few months more will witness the completion of another electric tramway line between Callao and Lima. The road is about 10 miles long, double track. The opening of this road will have a marked effect in drawing Lima and its port, Callao, even more closely together than they are at present.

The Design of Induction Motors with Examples from Recent European Practice.

BY H. M. HOBART.

THROUGH the courtesy of the manufacturers, the writer has had recently placed at his disposal the particulars of a number of interesting English and Continental induction motor designs for large capacities. A tabulated analysis of these designs affords an opportunity of illustrating a useful practical method of carrying through the induction motor calculations. The designs are set forth in Table I in columns *A*, *B*, *C* and *D*. In column *A* is given a motor of Messrs. Brown, Boveri & Co. (Switzerland). The design in column *B* is by Mr. Danielson and is built by the Allmana Svenska Elektriska Aktiebolaget, of Westeras, Sweden. The design in column *C* is that of a motor by the Alioth Company, of Basel, Switzerland. The motor in column *D* was designed by Mr. Zani for Messrs. Dick, Kerr & Co., of Preston, England. In column *E* has been added the less recent but very interesting design by the Alioth Company, for a motor of 500 hp. The range of designs thus extends from 75 hp to 500 hp and the table is arranged in the order of increasing output, thus facilitating the study of the designs:

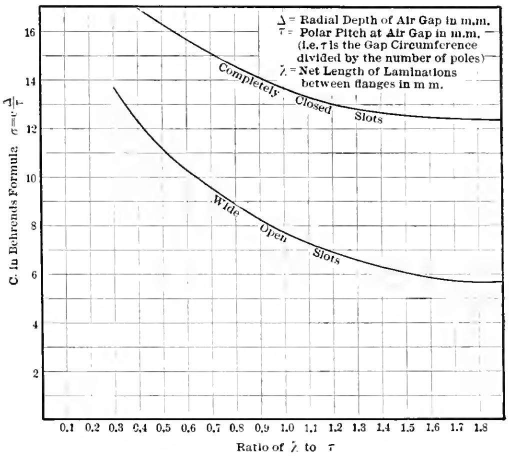

FIG. 1.—DIAGRAM OF CURVES.

The calculations in Table I are thought to be so clear as to require no explanation further than as regards the dispersion coefficient σ.

This has been calculated by employing Behrend's formula in the form

$$\sigma = C\,C^1 \frac{\triangle}{\tau},$$

in which

$\triangle$ = radial depth of air-gap.

and τ = polar pitch at air-gap.

C and C^1 are two constants obtained respectively from the curves of Figs. 1 and 2. C is dependent upon the ratio $\frac{\lambda}{\tau}$, in which λ = core length between flanges. In the curves for C suitable allowance is made for the inductance of the end connections. C^1 is dependent upon $\triangle \times H$, in which H equals the average of the number of slots per pole on stator and rotor. In the curve for C^1 suitable allowance is made for the so-called "zig-zag" dispersion over the heads of the teeth.

The curve of Fig. 2 shows the great importance of employing a high value for $\triangle \times H$, for below 0.75 the curve rises rapidly and generally renders futile any attempt to improve the power factor by means of decreasing the radial depth of the air-gap. This "zig-zag" dispersion is almost negligible with many slots and moderately

deep air-gaps, but with few slots and short air-gaps it may rise to a very high figure, and thus it appears that very short air-gaps, besides being mechanically undesirable, lead to far less gain than is generally believed. The range of satisfactory practical designs generally lies between values of 0.8 and 4.0 for $\triangle \times H$, though

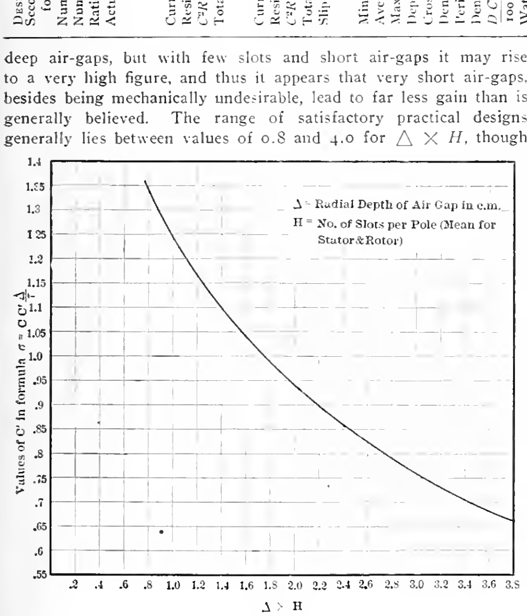

FIG. 2.—CURVE.

for very small motors, values less than 0.8 must occasionally be used, and a precise predetermination of σ is then rendered difficult owing to the inaccuracy in estimating the "zig-zag" component of the total dispersion. With the tendency to employ lower periodicities, the values for both $\triangle$ and H will increase in the near future. This analysis of the phenomena should afford an additional argument against relying on high values of τ and small values of $\triangle$ as means for obtaining high power factors. The curves of Fig. 1 show that high values of τ may lead to such increased inductance of the end connections as to limit improvement in this direction, and the curve of Fig. 2 shows that when $\triangle$ is decreased beyond certain limits, the "zig-zag" dispersion increases so rapidly as to limit any considerable power factor improvement by this means.

The data set forth in Table II (page 808) on 57 induction motors, of eight different manufacturers in four different countries, contain ample proof that the estimation of σ by means of the curves in Figs. 1 and 2 gives results in far closer agreement with the observed results than has heretofore been believed to be possible. In compiling Table II I have employed all the cases I had at hand, where the observed results could be considered as having been carried out with reasonable care and intelligence, omitting only those cases for which $\triangle \times H$ was less than 0.75, since these may be considered to be exceptional, and to be in general, undesirable when they can be avoided. A large number of these examples of observed results were obtained from the data in Dr. Behn-Eschenburg's recent very valuable paper on the dispersion coefficient.* In this paper Dr. Behn-Eschenburg set forth a collection of experimental data of very great value. He also deduced a very interesting formula for estimating σ, which had the great advantage of being in the form of three separate terms relating respectively to the slot dispersion, the flank dispersion and the "zig-zag" dispersion. The results by Dr. Behn-Eschenburg's method do not, however, agree with observations so well as do those obtained by the method employed in this article.

These curves in Figs. 1 and 2 probably permit of a more accurate determination of σ than is in practice generally obtained in factory tests and with the customary rough methods employed in mechanical measurements of $\triangle$, the radial depth of the air-gap.

For squirrel-cage motors, a third constant, C^{11}, may be added and the formula may be written:

$$\sigma = C\,C^{1}\,C^{11}\,\frac{\triangle}{\tau}$$

C^{11} will generally be about 0.75, and where no more precise basis for its determination is available, it should be so taken.

* Institution of Electrical Engrs. of Great Britain, Dec. 10, 1903.

The Elementary Principles of Transformer Design.—II.
(Concluded.)

By Prof. Thomas Gray.

In the discussion just given the links have, as already stated, been considered as rectangular with square corners. and it will be noticed that in the applications given below no account is taken of the variable section at these corners or of the variable flux across the section due to variation of length between the inside and outside of the link. The coefficient of hysteresis is assumed to apply to the sections considered. There is, however, an element involved here which is of considerable importance and which is generally, if not always, neglected. Suppose, for example, that the coefficient and exponent in the equation, $H = h\,B^a$, for heat dissipation in the iron, has been determined from straight samples or from rings in which the internal and external radii do not differ greatly from each other. The question naturally arises, Can the value so obtained be applied to the ordinary forms? As an illustration, assume a circular ring the material section of which is rectangular, internal radius r_1 and external radius r_2. For moderate variations near ordinary values of induction density, B may be taken as inversely as the radius.

Let, therefore, $B = \dfrac{a}{x}$ where a is a constant and x is the radius of any elementary ring. Let the breadth of the ring section be unity and assume the ordinary form of expression for the hysteresis as given above.

Then

$$d\,H = h\,B^a.\ 2\pi\ x\ d\,x = 2\pi\ h\ a^a\ x^{1-a}\ d\,x;$$

$$\therefore \qquad H = 2\pi\,h\,a^a\,\frac{r_2^{\,2-a} - r_1^{\,2-a}}{2 - a}.$$

When $a = 1$,

$$H = 2\pi\ h\ a\ (r_2 - r_1),$$

which is the same as would be given by a uniform induction equal to the mean induction multiplied by the volume. In the actual case, however, a is greater than unity, approximates in fact, as was shown by Steinmetz, to 1.6 for ordinary working ranges of induction. In the general case the value of H calculated from the mean value of B would be:

$$H^1 = \pi\,h\ (r_2^{\,2} - r_1^{\,2})\left(\frac{2a}{r_1 + r_2}\right)^{a-1}$$

$$\therefore \qquad \frac{H}{H^1} = \frac{2^{a-1}\ (r_2^{\,2-a} - r_1^{\,2-a})\ (r_2 + r_1)^{a-1}}{(2 - a)\ (r_2 - r_1)}$$

When $a = 1.6$ this becomes

$$\frac{H}{H^1} = \frac{10\,(r_2^{\,1.1} - r_1^{\,1.1})\ (r_2 + r_1)^{0.6}}{2^{2.6}\ (r_2 - r_1)}$$

Suppose, as a practical case, that $r_1 = 5$ and $r_2 = 15$.

Then $H = 1.035H^1$, which shows an increase due to a difference of radius of 3.5 per cent. If $r_1 = 1$ and $r_2 = 5$, the difference is 9.2 per cent., and when $r_1 = 0$ and $r_2 = 5$, $H = 1.65H_1$. This last is, of course, an extreme case, but it is evident that the data to be used in the design of transformers should be determined from samples of similar shape to that proposed for use.

APPLICATION TO TRANSFORMER DESIGN.

Let the induction per sq. cm. of the core section be represented by $B \sin \omega\ t$, and, therefore, the total induction, $A\,B \sin \omega\ t$; then, since the magnetizing current is very small, the amplitude of the e.m.f. applied will, when the transformer is not loaded, be practically equal to that induced by self-induction. Thus, $E = \dfrac{n\,A\,B\,\omega}{10^8}$, where n is the number of windings on the primary coil. If P be the required full-load activity, C the square root of the mean square of the full-load current in the primary, and the power factor for full load be taken as unity, $P = E\,C/\sqrt{2}$. Taking f as the average current per sq. cm. of coil section, the heat generated in the coils will be approximately $\dfrac{4}{10^6}\,f^2 v$ on the assumption that 50 per cent. of the combined coil section is copper and that the working temperature is 80° C. The coil sections should be so proportioned that the heat dissipations on the load which gives maximum efficiency, assumed in the example given as the full load, are equal. On full load as thus defined the heat generated in the iron due to combined hysteresis and eddy current should be equal to the total heat generated in the coils. This latter can in general be assumed to be entirely due to the ohmic resistance of the coils and the load currents, because in a transformer of good design there is practically no magnetic field in the coil space. In order to obtain definite numerical results for comparison the total iron heat has been assumed to follow the law given by Steinmetz, namely, $H = h\,B^a$, where $a = 1.6$. The value assumed for h, namely, $18/10^{11}$ in watts per cu. cm. per cycle per second, is founded on the writer's own measurements on transformers and agrees fairly well with similar measurements by Kapp and others. Better iron can no doubt be obtained and less insulation may in many cases be found sufficient, both of which would tend towards less weight and higher efficiency.

The value of f is determined from the number of wires per sq. cm., and the current in each and this will in general be different for the primary and secondary coil. No error is introduced by assuming half the coil space to each and a simple change of insulation, the same wires being used.

Hence, $f = 2n_1\ C/A = 2\sqrt{2n_1}\ P/E\,A$. Equating the dissipation of energy in the coils to that in the iron,

$$\frac{4}{10^6}\ .\ f^2 v = \frac{32}{10^6}\ .\ \frac{n_1^{\,2}\,P^2}{E^2 A^2}\,v = \frac{\omega}{2\pi}\ .\ h\,B^a\,v_1.$$

Another equation is obtained from the condition that a certain area of radiating surface must be allowed for each watt of heat dissipated. Let the total exposed surface be S and let s be the surface allowed per watt. The value of s depends on the method of cooling and the allowable rise of temperature above the surrounding air. Since the total heat is twice that generated in the iron,

$$2\,\frac{\omega}{2\pi}\ .\ h\,B^a\,v_1\,s = S.$$

Now, the values of $\dfrac{S\,a}{v_1}$ are shown by means of curves in Figs. 2 and 4 for different ratios of sections or volumes. Let the proper value for any case under consideration be g. Then

$$\frac{\omega}{\pi}\ .\ h\,B^a\,s\,a = \frac{S\,a}{v_1} = g.$$

It thus appears that for the determination of the proper induction, B_1, the proper number of windings, n, in the primary coil and the proper size indicated by a. A or v, etc., the following three equations besides those obtained for the ratios of the linear dimensions, etc., are available:

$$h\,B^a = \frac{\pi}{\omega}\ .\ \frac{g}{s\,a} \qquad (21)$$

$$h\,B^a = \frac{32}{10^6}\ .\ \frac{n_1^{\,2}\,P^2}{E^2 A^2}\ .\ \frac{v}{v_1}\ .\ \frac{2\pi}{\omega} \qquad (22)$$

$$A_1 \text{ or } x\,A_1 \text{ or } x\,x_1\,a^2 = \frac{10^8 E}{n_1\ B\ \omega}. \qquad (23)$$

In equation (23) x_1 is put for b/a, which for any given ratio of sections or volumes can be found from the curves given.

Raising (21) to the fourth power and dividing by (22),

$$(h\,B^a)^3 = \frac{10^6}{64}\ .\left(\frac{\pi}{\omega}\right)^3.\left(\frac{g}{s}\right)^4.\ \frac{v_1}{v}\ .\ \frac{E^2 x_1^{\,2}}{n^2 P^2} \qquad (24)$$

From (21) and (23),

$$\frac{(h\,B^a)^4}{B^2} = \left(\frac{\pi}{\omega}\right)^4 \left(\frac{g}{s}\right)^4 \frac{n_1^2\,\omega^2}{10^{16}\,E^2} \cdot x^2 x_1^2 \qquad (25)$$

(24) × (25) gives

$$\frac{(h\,B^a)^7}{B^2} = \frac{1}{64 \times 10^{19}} \cdot \left(\frac{\pi}{\omega}\right)^7 \left(\frac{g}{s}\right)^8 \cdot \frac{v_1}{v} \cdot \frac{\omega^2\,x_1^4\,x^2}{P^2} \qquad (26)$$

Hence, if $a = 1.6$ and $h = \dfrac{18}{10^{11}}$,

$$B^{9.2} = \frac{10^{67}}{64 \times 18} \cdot \left(\frac{\pi}{\omega}\right)^7 \left(\frac{g}{s}\right)^8 \cdot \frac{v_1}{v} \cdot \frac{\omega^2\,x_1^4\,x^2}{P^2}$$

$$= \frac{10^{67} \times \pi^2}{64 \times 32 \times 18^7} \left(\frac{2\pi}{\omega}\right)^5 \left(\frac{g}{s}\right)^8 \cdot \frac{v_1}{v} \cdot \frac{x_1^4\,x^2}{P^2}$$

$$= 7.866 \times 10^{55} \times \left(\frac{2\pi}{\omega}\right)^5 \left(\frac{g}{s}\right)^8 \cdot \frac{v}{v_1} \cdot \frac{x_1^4\,x^2}{P^2} \qquad (27)$$

which serves to determine B. Then, from (21),

$$a = \frac{2\pi}{\omega} \cdot \frac{g}{s} \cdot \frac{10^{11}}{36\,B^{1.6}} \qquad (28)$$

and from (23),

$$n_1 = \frac{10^8\,E}{x\,x_1\,B\,\omega\,a_1} \qquad (29)$$

$$H = 2 \times 18 B^{1.6}\,v_1\,\omega/2\pi \times 10^{11}.$$

It would be better to determine n first, because in practice the number of terms should be a multiple of the transformation ratio and the change of n to fulfill this condition implies a corresponding change in a and B. The equation for the direct determination of n is not, however, convenient for calculation because of the fractional exponents involved. The number given in the following examples are those given by the above equations without any adjustment. The value of s assumed is 30, which is about the area required for the transformer in ordinary use without oil or artificial cooling. When the case is filled with oil s may be reduced to 20, even on continuous use, and hence a considerable saving in weight and an increase in efficiency is obtained.

Particular Examples.—Example (1): A two-link transformer is to have a capacity $P = 1{,}000$ watts, where $E = 3{,}000$ volts, $\dfrac{\omega}{2\pi} = 100$, $x = 1$, and $s = 30$.

Here $v = v_1$, $x_1 = 3$ and $g = 3.166$, and from equations (27) (29) the following values are found:

$B = 4{,}950$,	$A = A_1 = 38.75$,
$n = 2{,}490$,	$v = v_1 = 1{,}672$,
$a = 3.59$,	$v + v_1 = 5{,}344$.
$b = 10.78$,	

Total heat dissipated per second $= H = 2 \times 18 \times 4{,}950^{1.6} \times 1{,}672 \times 100 = 49.08$ watts.

Efficiency $= 95.1$ per cent.

Example (2): With the same data as for (1) except that $P = 10$ kw, the following results are obtained:

$B = 3{,}000$,	$A = A_1 = 192.3$,
$n = 828$,	$v = v_1 = 18{,}470$,
$a = 8.01$,	$v + v_1 = 36{,}940$,
$b = 24.02$,	$H = 243.5$,
	Efficiency $= 97.6$ per cent.

Example (3): Same data as for (1) and (2) except that $P = 100$ kw.

$B = 1{,}819$,	$A = A_1 = 954$,
$n = 275$,	$v = v_1 = 204{,}100$,
$a = 17.83$,	$v + v_1 = 408{,}200$,
$b = 53.489$,	$H = 1{,}208$,
	Efficiency $= 98.8$ per cent.

Example (4): A three-link core transformer is to have a capacity of one kilowatt when $E = 3{,}000$ and $A = A_1$.

The same formulæ apply in this case, but when $x = 1$, $x_1 = 2$, $b_1/a_1 = 3$, $v_1/v = 1.086$, and $g = 3.462$, the results are:

$B = 4{,}530$,	$v = 1{,}590$,
$n = 2{,}565$,	$v_1 = 1{,}730$,
$a = 4.539$,	$v + v_1 = 3{,}320$,
$b = 9.078$,	$H = 44.04$,
$A = A_1 = 41.17$,	Efficiency $= 95.6$ per cent.
$a_1 = 3.704$,	
$b_1 = 11.112$,	

Example (5): Same as (4), except that $P = 10$ kw.

$B = 2{,}747$,	$A = A_1 = 204.2$,
$n = 853$,	$v = 17{,}600$,
$a = 10.1$,	$v = 19{,}110$,
$b = 20.2$,	$v + v_1 = 36{,}710$,
$a_1 = 8.25$,	$H = 218.3$,
$b_1 = 24.75$,	Efficiency $= 97.8$ per cent.

Example (6): Same as (4), with the exception that the capacity is 100 kw.

$B = 1{,}664$,	$A = A_1 = 1{,}015$,
$n = 283$,	$v = 195{,}100$,
$a = 22.52$,	$v_1 = 212{,}100$,
$b = 45.04$,	$v + v_1 = 407{,}200$,
$a_1 = 18.39$,	$H = 1{,}087$,
$b_1 = 55.17$,	Efficiency $= 99.1$ per cent.

Example (7): Take the same case as (5), with the modification that the iron section is half the coil section, or $x = \frac{1}{2}$. In this case $v_1/v = .796$, $x_1 = 3$, $b_1/a_1 = 2$, and $g = 4.755$.

Example (7):

$B = 3{,}588$,	$A = 245$,
$n = 1{,}086$,	$A_1 = 122.5$,
$a = 9.04$,	$v = 15{,}940$,
$b = 27.12$,	$v_1 = 12{,}700$,
$a_1 = 7.83$,	$v + v_1 = 28{,}640$,
$b_1 = 15.65$,	$H = 222.6$,
	Efficiency $= 97.8$ per cent.

Comparing these results with those obtained in example (5), it appears that there is an advantage in the reduction of weight and in increased induction density, which for most kinds of good iron would mean greater permeability. The dissipation of energy is, of course, slightly greater, but only a little over 4 watts. For transformers of this type considerable economy of first cost will be got by making the iron section considerably smaller than the coil section.

Shell Transformers.—In the case of the shell type the double link is iron and the equations (27)—(29) have to be modified, as follows:

$$B^{9.2} = 7.866 \times 10^{55} \left(\frac{2\pi}{\omega}\right)^5 \left(\frac{g}{s}\right)^8 \left(\frac{v}{v_1}\right)^7 \frac{x_2^4}{x^2\,P^2} \qquad (30)$$

$$a_1 = \frac{2\pi}{\omega} \cdot \frac{g}{s} \cdot \frac{v}{v_1} \cdot \frac{10^{11}}{36\,B^{1.6}} \qquad (31)$$

$$n_1 = \frac{10^8\,E}{x_2\,B\,\omega\,a_1^2} \qquad (32)$$

In these equations, $x_2 = b_1/a_1$ and g is put $= \dfrac{S\,a_1}{v_1}$, instead of $\dfrac{S\,a}{v_1}$, so that the values can be more conveniently taken from the curve, Fig. 4.

Example (8): When the shell type is taken with the same data as in example (4) the only changes to be noted are that $x_2 = b_1/a_1$

$= 2$, being now the ratio of the dimensions of the total section of the double link, and that $\left(\frac{v}{v_1}\right)^7$ appears in the equation (30), instead of $\frac{v_1}{v}$ in equation (27). The results are as follows:

Example (8): Capacity, one kilowatt. $E = 3{,}000$.

$B = 4{,}778$,	$A = A_1 = 40.82$,
$n = 2{,}445$,	$v = 1{,}710$,
$a = 3.69$,	$v_1 = 1{,}570$,
$b = 11.07$,	$v + v_1 = 3{,}280$,
$a_1 = 4.52$,	$H = 43.6$,
$b_1 = 9.03$,	Efficiency $= 95.6$ per cent.

Example (9): Same as (8), with the exception that the capacity is 10 kw.

$B = 2{,}896$,	$A = A_1 = 202.7$,
$n = 813$,	$v = 18{,}890$,
$a = 8.22$,	$v_1 = 17{,}400$,
$b = 24.65$,	$v + v_1 = 36{,}290$,
$a_1 = 10.07$,	$H = 216.2$,
$b_1 = 20.13$,	Efficiency $= 97.84$ per cent.

Example (10): Keeping other things the same as in example (9), let the iron section be made twice the copper section. The results then become:

$B = 3{,}091$,	$A = 124.9$,
$n = 618$,	$A_1 = 249.7$,
$a = 7.90$,	$v = 13{,}060$,
$b = 15.80$,	$v_1 = 16{,}400$,
$a_1 = 9.12$,	$v + v_1 = 28{,}140$,
$b_1 = 27.37$,	$H = 226.6$,
	Efficiency $= 97.7$ per cent.

Example (11): The same as (10), with exception of the ratio of iron to copper section. In this $A_1 = 5A$. The ratio $b_1/a_1 = 6$ and $b/a = 1.4$ in this case.

$B = 3{,}770$,	$A = 59.93$,
$n = 420$,	$A_1 = 299.6$,
$a = 6.54$,	$v = 7{,}362$,
$b = 9.16$,	$v_1 = 13{,}640$,
$a_1 = 7.06$,	$v + v_1 = 21{,}000$,
$b_1 = 42.39$,	$H = 260.2$,
	Efficiency $= 97.4$.

When a transformer is on the circuit continuously, but only loaded for a few hours each day a greater all-day average efficiency may be obtained by choosing a transformer so designed that the iron heat dissipation is considerably less than that of the coil when loaded. The efficiency is, of course, smaller on full load. For such a case equations (29) and (30) should be modified to read:

$$B^{9.2} = 7.866 \times 10^{55} \left(\frac{2\pi}{\omega}\right)^5 \left(\frac{g}{s}\right) \left(\frac{v}{v_1}\right)^7 \frac{x_2^{\,4}}{x^2 P^2} \cdot \frac{m-1}{m^8} \qquad (30)_2$$

$$a_1 = \frac{1}{m} \cdot \frac{2\pi}{\omega} \cdot \frac{g}{s} \cdot \frac{v}{v_1} \cdot \frac{10^{11}}{86\, B^{1.6}} \qquad (31)_2$$

Similar changes have, of course, to be made in equations (27) and (29) for the core types. In forming the modified equations the total heat dissipation is supposed to be m times the hysteresis dissipation.

Example (12): Let $m = 3$ and the other data be the same as in example (9).

$B = 2{,}195$,	$A_1 = 218.6$,
$n = 921$,	$v = 21{,}180$,
$a = 8.53$,	$v_1 = 19{,}510$,
$b = 25.60$,	$v + v_1 = 40{,}690$,
$a_1 = 10.45$,	$Hi = 77.9$,
$b_1 = 20.90$,	$Hc = 155.8$,
$A = 218.6$,	$Hi + Hc = 233.7$,
	Efficiency $= 97.66$.

The efficiency is thus 97.66 instead of 97.84, and the weight is considerably increased, but when the load is only on for six hours out of the twenty-four there is a saving of about 600 watts-hours per day.

The numbers given in the above examples were obtained by the aid of a four-place logarithm table and hence the fourth figure is probably in error in most cases. The results are, however, sufficient to indicate the comparative values of the different types which was the object in view. It will be observed that so far as efficiency is concerned there is little difference. The shell type gives a few watts dissipation than the core type and the core type with three links is a similar amount better than the two-link type. The comparison is better obtained from the values of H than from the percentage efficiency. A noticeable feature is the very considerable saving of weight and increase of induction density obtained by making the links of unequal section. This involves some loss of efficiency, of course, and the question as to how far it can be economically carried has to be determined by considerations of relative cost of material and energy. Curves showing relative weights and efficiencies for different ratios of section can be easily constructd for any particular type and by aid of these the best form for any particular case can be readily estimated. The last example given illustrates how the dimensions may be calculated for a transformer suitable for cases where the primary is continuously on the leads, but the secondary only loaded for a part of the day. The section may, of course, be made unequal in this as in the other cases with advantage as to weight, but possibly with loss of efficiency. It is not, however, essential to economy that a transformer for this purpose should have a smaller iron than coil section. The controlling elements are the induction density and the actual volume of the iron. A transformer of given capacity having the iron section greater than the coil section may have less volume of iron in it than one of the same capacity with equal sections. The sections change shape and the whole volume may become smaller with a sacrifice of efficiency. As indicated above, however, the all-day efficiency may be increased, although the full-load efficiency is diminished.

The capacities of the transformers discussed above have been estimated from the load which gives equal iron and copper losses. In most cases such a transformer will carry a large overload for a short time with safety. The radiating surface will, of course, be too small for continuous use on overload unless artificial cooling is resorted to. When oil cooling, for instance, is used, at least one and a half times the heat can be carried off for the same temperature. A transformer designed for air cooling should not be used with oil and simply loaded higher. A new design should be worked out using the proper value of s in the equations.

The form of link assumed in the above discussion is rectangular with sharp corners. Using the same notation the following modification may be given:

(1) *Two-Link Type.*—(*a*). Links with corners rounded to radius a and a_1:

$$a b = A \qquad a_1 b_1 = A_1$$

$$l = 2\,(a_1 + b_1) + \pi a \qquad l = 2\,(a + b) + \pi a$$

$$\frac{b}{a} = \frac{A_1 + \frac{\pi}{} A}{A_1} = \frac{b_1 + \left(\frac{\pi^2}{4} - 1\right) a_1}{b_1 - a_1}$$

$$\frac{b_1}{a_1} = \frac{A + \frac{\pi}{2} A_1}{A} = \frac{b + \left(\frac{\pi^2}{4} - 1\right) a}{b - a}$$

When $A = A_1$,

$$\frac{b}{a} = \frac{\pi}{2} + 1 = \frac{b_1}{a_1} \qquad a = a_1 \qquad b = b_1$$

(*b*) Links with the edges of the sections and ends of the links both semicircles:

$$A = a\,(b - a) + \frac{\pi}{4} a^2 \qquad A_1 = a_1\,(b_1 - a_1) + \frac{\pi}{4} a_1^{\,2}$$

$$l = 2(b_1 - a_1) + \pi(a + a_1) \qquad l_1 = 2(b - a) + \pi(a + a_1)$$

$$\frac{b}{a} = \frac{A_1(\pi - 3) + \frac{\pi}{2}A}{A_1} = \frac{(\pi-3)\{b_1 - (\pi-3)a_1\} + \frac{\pi}{4}a_1^2}{b_1 - (\pi - 3)a_1}$$

$$= \pi - 3 + \frac{\pi^2 a_1}{4\{b_1 - (\pi - 3)a_1\}}$$

$$\frac{b_1}{a_1} = \frac{A(\pi - 3) + \frac{\pi}{2}A_1}{A} = \pi - 3 + \frac{\pi^2 a}{4\{b - (\pi - 3)a\}}$$

When $A = A_1$,

$$\frac{b}{a} = 3\left(\frac{\pi}{2} - 1\right) = \frac{b_1}{a_1} \qquad a = a_1 \qquad b = b_1$$

(2) *Three-Link Type.* (*a*) The corners rounded, but section of links rectangular. Let a, b, A and l refer to double-link:

$$ab = A \qquad a_1 b_1 = A_1$$

$$l = 2(a_1 + b_1) + \frac{\pi}{2}a \qquad l_1 = 2(a + b) + \pi a_1$$

$$\frac{b}{a} = \frac{A_1 + \frac{\pi}{4}A}{A_1} = \frac{b_1 + \left(\frac{\pi^2}{8} - 1\right)a_1}{b_1 - a}$$

$$\frac{b_1}{a_1} = \frac{A + \frac{\pi}{4}A_1}{A_1} = \frac{b + \left(\frac{\pi^2}{4} - 1\right)a}{b - a}$$

(*b*) In the core type the edges of the section of the iron link may be made semicircles while the sections of the coils are rectangular:

$$A = ab \qquad A_1 = a_1(b_1 - a_1) + \frac{\pi}{4}a_1^2$$

$$l = 2(b_1 - a_1) + \pi\left(a_1 + \frac{a}{2}\right) \qquad l_1 = 2(b - a) + \pi a_1$$

$$\frac{b}{a} = \frac{A_1 + \frac{\pi}{4}A}{A_1} = \frac{b_1 + \frac{\pi}{4}\left(\frac{\pi}{2} - 1\right)a_1}{b_1 - \frac{\pi}{4}a_1}$$

$$\frac{b_1}{a_1} = \frac{\pi}{4} \cdot \frac{A + 2A_1}{A} = \frac{\pi}{4} \cdot \frac{b + \left(\frac{\pi}{2} - 1\right)a}{b - a}$$

When $A = A_1$ the ratios $\frac{b}{a}$ and $\frac{b_1}{a_1}$ become

$$\frac{b}{a} = \frac{\pi}{4} + 1 \qquad \frac{b_1}{a_1} = \frac{3}{4}\pi$$

Other modifications may be readily obtained and the values of these ratios in terms of the corresponding volume or section ratios expressed by means of curves like those given in Figs. 2 and 4, but sufficient has probably been given to illustrate the method of proceeding.

The Braun Tube in the Study of Alternating Currents.

In a paper read before the Russian Physico-Chemical Society, Prof. A. Petrovski described an application of the Braun tube to the study of alternating current. The Braun tube is from 2 to 3 cm. in diameter, carrying at one end an enlarged cylindrical part 10 to 15 cm. in diameter and 10 to 30 cm. long. In this enlarged portion is a plate placed perpendicular to the axis of the tube, the surface of which is coated with a fluorescent substance. At the opposite end of the tube, in the narrow part, is a small aluminum disc which is also perpendicular to the axis. The disc is fixed on a platinum wire soldered into the end of the tube. During operation the wire is connected with the negative pole. In another part of the tube is a second terminal, which connects with the positive pole. After a vacuum has been formed in the tube, the aluminum disc emits the well-known radiation characteristic of the Crookes tube, which is directed along the axis of the tube. Midway in the narrow portion is fixed a diaphragm which allows only the central part of the beam to pass. The latter then crosses the wider portion or bulb, and falls upon the fluorescent screen, producing a small blue spot.

The beam has the well-known property of being deflected in one side under the action of the magnetic field, like a wire carrying a current. If the tube is in the horizontal position and the magnetic field is vertical, the beam will be deflected in the horizontal sense, and the spot of light on the screen will be deflected to the right or left, according to the field's direction. If, however, the field is horizontal, the spot will be displaced up or down. Such displacement may be considered as proportional to the intensity of the field. If the intensity of the field be varied according to the time, the shifting of the spot will follow such variations, and the distance of the spot

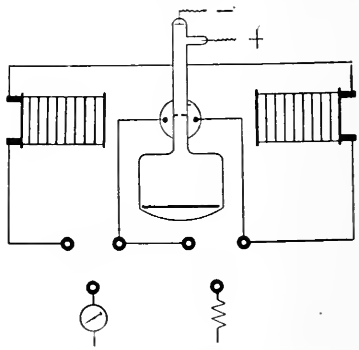

FIG. 1.—ARRANGEMENT OF CIRCUITS.

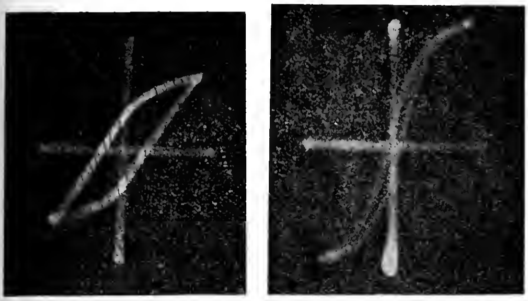
from the center of the screen is considered as proportioned to the field strength at a given moment. Where a solenoid is used to produce the magnetic field, the deflection of the spot is likewise proportional to the current strength in the coil at any given instant.

Owing to these properties the Braun tube can be used to advantage in the study of variable currents and has a great practised value for observing alternating-current phenomena. In general practice there are three main phenomena of alternating currents which are to be studied, namely, hysteresis, phase difference and rotating field. Each of these cases was examined in turn.

To study the phenomena of hysteresis with the Braun tube, the arrangements of circuits shown in Fig. 1 was used. Around the tube are placed three solenoids. The first of these is placed above or below the tube and perpendicular to its axis. The current in this coil creates a magnetic field which causes the spot of light to take a horizontal movement. The two other coils are placed horizontally on each side of the tube, as shown, and the current flowing in them gives the spot a vertical deflection. The latter coils are connected differentially, so that in the normal case their magnetic action is opposed, and the effect which one of them would exert on the spot is annulled by that of the second. The tube can thus be placed in such a position that the action of the horizontal coils is mutually destroyed. But if in one of the coils is placed a piece of the iron to be experimented with, the action of the latter, by changing the field, gives the spot a vertical direction. The deflection of the spot from its normal position will measure the value of the magnetic induction in the sample at any instant. This corresponds to the ordinate of the hysteresis curve, as usual. As to the third, or upper coil, it produces a horizontal deflection of the spot which at each instant will be proportional to the current flowing through it.

The three solenoids are all connected in series, so that the same



FIGS. 2 AND 3.—HYSTERESIS CURVES.

current which gives the horizontal movement to the spot also produces the magnetization of the sample. The horizontal deflection represents the value of the field strength at any given time or the abscissa of the hysteresis curve. When the current flows through the two sets of coils in series, the spot will take a movement such

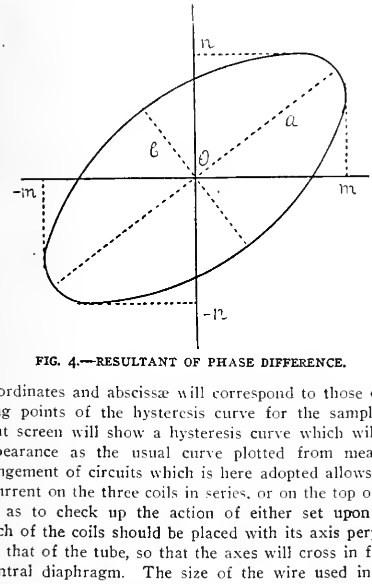


FIG. 4.—RESULTANT OF PHASE DIFFERENCE.

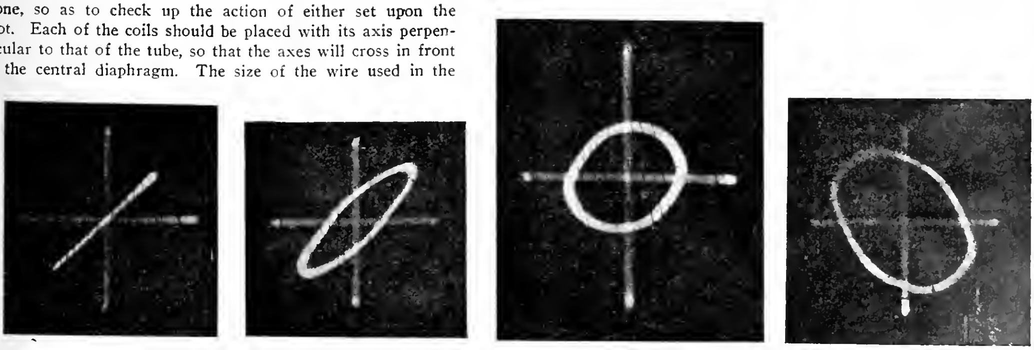
that the ordinates and abscissæ will correspond to those of the corresponding points of the hysteresis curve for the sample, and the fluorescent screen will show a hysteresis curve which will have the same appearance as the usual curve plotted from measurements. The arrangement of circuits which is here adopted allows of throwing the current on the three coils in series, or on the top or side coils alone, so as to check up the action of either set upon the spot. Each of the coils should be placed with its axis perpendicular to that of the tube, so that the axes will cross in front of the central diaphragm. The size of the wire used in the



FIGS. 6, 7, 8 AND 9.—PHASE DIFFERENCES IN ALTERNATING CIRCUITS.

solenoids and also the number of turns are chosen according to the current strength which is used. The light which is emitted by the fluorescent screen is of a high active quality, so that the curve can be photographed without difficulty on a short exposure. The camera should be focused beforehand upon some well-defined object, such as a lighted candle.

In Figs. 2 and 3 are shown photographic reproductions of hysteresis curves which were obtained in this way. The first curve is

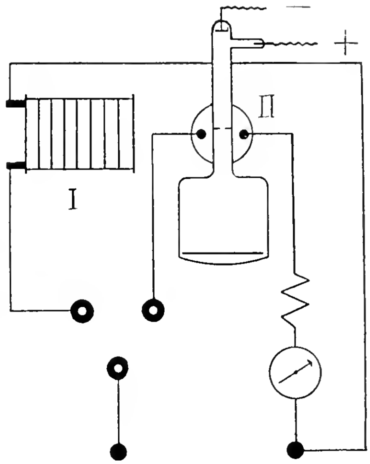


FIG. 5.—MEASUREMENT OF PHASE DIFFERENCES IN ALTERNATING CIRCUITS.

that of a hard file-steel, while the second is the curve of an iron of bad quality. The photographs were taken without enlargement on a plate of average sensitiveness. The tube was supplied from a static machine having two discs of about 60 cm. diameter. The plate was given an exposure of about 1 minute in order to obtain the curve itself. To obtain the lines corresponding to the axes, about 10 seconds is necessary. It should be noted that in tracing the hysteresis curve the axis of abscissæ should not be drawn directly from the curve, but the abscissæ are to be diminished in each case by the value of the so-called "demagnetizing force." As the apparatus does not give this correction automatically, it should be introduced when drawing the curve from the above data.

The use of the Braun tube with the present arrangement gives an easy method of determining the angle of lag between current and electromotive force in an alternating-current circuit, which is in general not easy to measure. In this apparatus the angle of lag, ϕ, is found by the superposition of two oscillatory movements. If we suppose a point which is traveling under the influence of two combined and synchronous impulses, the first in the horizontal and the second in the vertical plane, the resultant of the two movements will be a closed curve. If we use two oscillatory movements, such as a harmonic or sinusoid, it is shown theoretically that the resultant formed by adding their movements will be a sraight line in case there is no difference of phase between the two. Should the phase difference have a certain value, ϕ, the resultant takes the form of an ellipse whose proportions depend mainly upon the value of ϕ. See Fig. 4. It will be remarked that the deflection of the large axis of the ellipse is represented in general by the ratio of the values of the amplitudes, *o m* and *o n*. In the special case where *o m* and *o n* are equal, the inclination of the resulting axis of the ellipse is 45°. The ratio of the length of the smaller axis, *b*, to that of the larger axis, *a*, gives us the tangent of the angle, ϕ:

$$tan\ \frac{\phi}{2} = \frac{b}{a}.$$

These conditions can be applied to the measurement of the angle, ϕ, in the case of alternating currents, in which case we use the system shown in Fig. 5. Near the Braun tube are disposed two coils, *I* and *II*. Coil *I* has many turns of fine wire and takes its current directly from the terminals of the station. Like a voltmeter coil, it does not produce an appreciable effect on the form of the main current. Coil *II* is connected in the main circuit and has a few turns of heavy wire in order to show the current effects. The first coil, owing to its position and the influence of the alternating current which passes in it, gives to the spot an oscillatory movement in a vertical direction. In like manner, coil *II* gives a horizontal movement to the spot. If current is flowing at the same time in *I* and *II*, the spot will take an elliptical movement. If now we displace coil *I* we can easily reach a point where the amplitudes of vibration in the vertical and horizontal sense are equal. Then after measuring the large and small axis of the ellipse thus produced, we find the value for the phase angle according to the above formula. The current flowing in coil *I* equals the number of amperes in the main line. If the ohmic resistance of coil *I* is very high in proportion to its coefficient of self-induction, the current in it will not lag perceptibly behind the e.m.f., so that the relation of the two axes of the ellipse gives the value of the tangent of one-half the angle very closely, representing the lag between the voltage and current waves in the main circuit.

If the resistance of the coil *I* is not very high with relation to the self-induction, the current in the coil will lag behind the voltage wave. The result will not be quite exact, therefore, but it is not difficult to make the proper correction. The curves which are thus obtained can be photographed in the same way as the hysteresis curves. In Figs. 6, 7, 8 and 9 will be observed some of the results which have been obtained by this method. In the first case (Fig. 6) the circuit contains no lag. In the second case (Fig. 7) there is a large self-induction in the circuit. Fig. 8 shows the effect when the self-induction is increased by putting an iron core into the coil. In the last experiment, Fig. 9, the ends of the circuit are open and connected across a condenser of large capacity. As in most cases the alternating-current waves have not an exact sine curve, the resulting form which the spot of light traces is not always a perfect ellipse.

In general the composition of two harmonic oscillatory movements gives an elliptical curve, as above considered, but in the particular case where the amplitudes of oscillation are equal and the difference of phase 90°, a circular form is produced. In like manner, the addition of three harmonic oscillatory movements can give a circle when the amplitudes of all the oscillations are equal and the phase difference is 120°.

The present system allows of investigating the conditions of the rotary field, such as is produced by these circuits spaced 120° apart, in a very satisfactory manner. It is possible to find out whether the rotary field is produced under the best conditions of regularity, which is so important for the good working of three-phase motors and is essential to prevent a loss of energy.

The apparatus for studying the rotary field is disposed on the same lines as the above, using three similar coils ranged around the tube. The axes of the coils are, as before, perpendicular to the axis of the tube, and the coils are spaced at 120° around this axis as a center. The wire of which the coils are wound is heavy enough to allow of introducing each of the coils into one of the phases of the current to be studied. On sending current into the circuit, the spot takes a circular movement: and if there are any irregularities under these conditions, they are shown by the appearance of the circular curve.

The experiments which have been carried on by M. Petrovski have given many interesting curves, and the method recommends itself by its simplicity and the satisfactory results which may be obtained with it in the study of alternating-current phenomena.

Annual Convention of the Iowa Electrical Association.

THE Iowa Electrical Association held its fourth annual convention at Des Moines, April 20 and 21, 1904. President D. F. McGee, of Red Oak, called the first session to order Wednesday morning, and introduced Mayor Mattern, of Des Moines, who welcomed the convention to that city. President McGee then made a brief address, in which he said that members and other central station men over the State were now learning that the Iowa Electrical Association was of great benefit to the central station men of the State. The station managers who never leave their home towns to learn what is being done in other places and to confer with other central station men—as they are able to do in an association of this kind—soon get into a rut, which is a great detriment to their business. The facilities for asking questions about particular points, which are afforded by the Iowa conventions, give the central station man the easiest means of getting out of such a rut.

Secretary W. S. Porter, of Eldora, in his report, said he had received letters from Missouri and Nebraska men, expressing a desire to attend the convention, and he had told them they would be welcome. It might be well for the Association to consider whether such men should be admitted merely as guests or given some rights of membership. He referred also to a movement among the electric railway men of the State to form an organization, a meeting for which purpose was to-day being held. He recommended that a committee be appointed to confer with the electric railway men and to consider whether it would be advisable for the electric railway and electric light men to join together in an association, or whether the two allied interests should be kept apart.

The treasurer's report, by Treasurer Rufus E. Lee, of Clarinda, showed a balance of $68 in the treasury. A ballot taken for the election of a nominating committee resulted in the election of W. J. Greene, of Cedar Rapids; W. S. Carson, of Iowa City; Austin Burt, of Waterloo; M. W. Hovey, of Marshalltown; W. H. Grover, of Cherokee; Prof. George W. Bissell, of Ames, and Robert Ferris, of Eldora.

CENTRAL STATION ACCOUNTING.

Robert Ferris, of Monmouth, Ill., owner of the Eldora electric light plant, gave a talk on station accounting, demonstrated by the various blanks which he employed in his central station business at Monmouth, Ill., and Eldora, Iowa. He requires every man in the employ of the company to make out a daily time sheet, showing the number of hours work on different jobs. The distribution of expense among the different accounts is made at the office. The only bookkeeping responsibility on the men is to make out their time sheets correctly. He requires a record to be written of every trouble report that comes in, even if the man answering the telephone goes himself immediately to remedy the trouble. In such a case the man upon receiving notice of trouble from a customer would make out a trouble slip, file it on the hook, and when the trouble had been fixed return to the office and make memorandum on the slip to that effect. In this way there is no danger when several reports of trouble come in at the same time that one of them will be overlooked or forgotten. These slips form also a record which can be referred to in case customers complain of interruption of the service at the end of the month when paying bills. The system of records devised by Mr. Ferris was founded upon the form of report required by the Massachusetts commission.

He outlined briefly the Massachusetts laws, which provide for the safeguarding of investments in public service corporations. Competition in the electric lighting business in a Massachusetts town cannot be started at random. It must be shown that existing companies are not giving the service that should be given, or that the rates are unreasonably high. If the city undertakes the construction of a municipal plant, it requires a vote of the people and a vote of the council.

Mr. Ferris makes it a practice to invoice a customer's equipment every year, so as to know what is connected with the station. At Monmouth, after taking charge of the plant, it had been found, upon investigation, that under the flat rate system of selling current each company was delivering about half of a kilowatt-hour per day per customer, for which it was receiving 3.7 cents per kilowatt-hour, or less than the cost of production. A change was made to selling current by meter, and a well-worded pamphlet with a few pages was prepared by Mr. Ferris, announcing the change. This was mailed to the customers, followed by a personal visit to each. The rate is 20 cents per kilowatt-hour up to an amount equivalent to 40 hours burning of the maximum number of lights turned on during the month. He explained why he considered a discount based on the maximum demand much fairer than a discount based simply on the amount of current used. For example, a small customer with a low maximum demand and using his lights a great many hours a day, would produce more revenue for the company than a large demand customer, using lights only a short time each day. If the discount were based simply on the total amount of energy consumed, the customer with a large number of lamps running a short time each day might get a better discount than the customer with the small maximum demand, who burned his lights continuously.

Referring again to the trouble slips, he said that men were required to record all of the time put in whether engaged on any specific work or not. Men kept for answering emergency and trouble calls put down the time doing nothing in the office along with the rest. In this way the manager could see when he could take a man off emergency trouble work and put him on other work. All the time put in by the men must be accounted for in some way. The system of bookkeeping was simply a double-entry system, in which everything was balanced.

UNIFORM ACCOUNTING.

Wednesday afternoon the discussion of central station accounting was continued by the reading of a paper by Austin Burt, of Waterloo, on "Uniform Accounting." Mr. Burt, in presenting his paper, said that he realized that 75 per cent. of the central stations in Iowa were in towns of less than 5,000 people. In such stations one man must be superintendent, bookkeeper and electrician. Any elaborate systems of bookkeeping are out of place. He considered it a question how much value the set of blanks he would present would be to the small companies. The question of bookkeeping forms for large stations he considered was taken up in a very complete way before the National Electric Light Association in 1903, by W. M. Anthony, and before the same body by Lieut. J. B. Cahoon, in 1900.

He described his power station log, which was made up by the engineer. The engineer plotted the load curve directly on this log. He considered it better for the engineer to do this than to add it to the bookkeeper's work, and further, a graphic load curve was of more interest to the power station operating man than the mere figures. On this log also are provided spaces, in which, by ruling horizontal lines, corresponding with the load curve, the time of operation of each generator can be seen at a glance. This gives an idea as to whether station machinery is being run as fully loaded as it should be. As to the value of watching this point, Mr. Burt cited the experience in his station, where a few years ago the load factor of the station or the percentage of the average load to the machinery operated, was 13 per cent. for 24 hours. That is, only 13 per cent. of the capacity of the machinery was being used as an average for the 24 hours. The load factor was now about 80 per cent. The coal consumption per kilowatt-hour cost 2.75 cents formerly, and is now 0.9 cent. This change has been brought about mainly by proportioning the generators operated to the load, and ceasing to operate generators for many hours very much underloaded. A small engine was purchased for operation during the hours of very light load. This small unit has proved a very good investment.

As to bookkeeping in connection with the distribution system, that connected with the reading of meters was the most important. He used a small card of a card index system for each meter, each card having space upon it for two years' readings. These cards are arranged in the order which the meter reader will follow on his route, and are given out to each meter reader. He believes in employing responsible men for meter readers, rather than boys. Nothing but the most trustworthy men are employed on this work, so that the company may be sure that each meter has been actually read, and not guessed at, and is furthermore read carefully, so that the customer can have no just cause of complaint or opportunity to say that the company's business was conducted in a slip-shod manner.

He formerly believed in bills showing on their face all the figures in connection with a meter reading, crowding as much onto the bill as possible, giving the last reading, present reading, the kilowatt-hours and the calculation of the discount. In fact, his bills used to contain all the arithmetic of the monthly transaction with the customer. He has come to believe that these figures simply confused the average customer, and he now uses a bill which contains simply the gross bill and the discount which is allowed for prompt payment. He found that there were fewer questions under the present system than under the old system. In adding up the total amount of current sold for the month, he recommended strongly the use of an adding machine. In his case he had been able to make arrangements with a local bank for the use of such a machine. He spoke of two good makes of adding machines, one of which cost $125 and the other $375.

As to time cards, he requires time cards made out on all work and O. K.'d by the foreman in charge of the job. Instead of carrying a ledger account with customers for whom small repair jobs and the like have been done, he uses what is practically a triplicate bill with stub. One bill is sent to the customer, another filed for the use of the collectors, and the third remaining in the book, to take the place of a ledger account. The stub at the bottom of the customer's bill is turned in by the collector with his cash as a memorandum. Mr. Burt also showed the forms he used for stock room and invoice accounts and for general monthly report of the total business.

CO-OPERATION WITH TROLLEY MANAGERS.

At this point L. D. Mathes, of the Union Electric Company, of Dubuque, Iowa, was introduced as a committee representing the electric railway men of Iowa, who were in session at the Kirkwood Hotel at the same time. The street railway men desired a conference with a committee of the Iowa Electrical Association to consider whether it would be advisable for the two branches of work to organize under the same association. Messrs. Burt, Carson and Greene were appointed a committee to visit the railway men's convention. As a result of the conference of this committee with the electric railway men, it was decided by the latter to form a separate organization and to arrange the time of annual convention, so that one day of the electric light convention would overlap that of the electric railway convention of the State. The two associations and those interested in both could, therefore, discuss topics of mutual interest during the one day that the conventions would overlap.

COMBUSTION OF IOWA COAL.

A very practical paper on the "Combustion of Iowa Coal" was read by Prof. George W. Bissell, of Iowa State College, Ames, the data of which should be of much value to those using coal from the Iowa veins.

In response to a question as to the relative heat value of Illinois and Iowa coal, Prof. Bissell said that as far as chemical analysis went, the coals of the two States were about the same. Mr. H. E. Chase said that it required more draft to burn the fine coals, and many steam plants in Iowa did not have sufficient draft, and hence had to burn lump coal. Aside from this, the cheapest coal was the best one to burn as a rule. Mr. Bowers said that in his plant, which burned from 50 to 100 tons of steam coal per day, they found that it took practically as much to do the work with the lump coal as with the slack.

President McGee asked whether an excessive stack was not necessary where a baffle was placed behind a bridge wall as described by Mr. Boyd. The latter said that it was not, and cited an example where the change was made without changing the stack and with a great improvement in the performance of the plant. Prof. Bissell thought that coal should be burned while it was in the furnace and not behind the bridge wall. This discussion ended here and an invitation was read from the Columbia Incandescent Lamp Company, of St. Louis, inviting any of the members who might visit St. Louis the coming summer to go through the Columbia lamp factory and see the processes of manufacture.

SCALE INCRUSTATION IN STEAM BOILERS FROM A CHEMICAL STANDPOINT.

Paul E. Bellemy, of Knoxville, Iowa, presented a paper on the above subject, in which he gave a general résumé of the principles of the several ways to attack boiler scale trouble, of scale formation and iron corrosion. One is to send the water to some of the reliable manufacturers of boiler compounds who will analyze it, furnish a proper neutralizing compound and give the quantity required to neutralize the scale. Another method is to employ some disinterested chemical expert to make an analysis and prescribe the kind and amount of reagents necessary to reduce the scale-forming salts to harmless salts. Some boiler compounds were nothing more than well-known cheap reagents colored in some way. In reply to a question as to how to test feed water after it was in the boilers to see whether the treatment was effecting the proper result, Mr. Bellamy said that the best way was to watch the practical result on the boilers.

Mr. Zahm described a method used by him at Mason City for introducing boiler compound in a closed tank located above the suction of the boiler feed pump. He further said that a galvanized-iron pan in the bottom of the boiler was a good thing. This pan is made just wide enough to go through the hand-hole above the bottom sheet and is suspended three or four inches above the bottom sheet of the boiler. The scale and mud settles upon it. Mr. Emory emphasized the necessity of operating a purifying system systematically and carefully. Too much boiler compound or reagent was worse than not enough.

STORAGE BATTERIES IN CONNECTION WITH A CENTRAL STATION.

Edward Reavy, of Davenport, read a paper on the above subject. A small central station, he said, cannot furnish current twenty-four hours of the day because of the light load during daylight and early morning hours, but stations would be able to give twenty-four hours' service with the aid of a storage battery during the hours of moderate load. He described a battery in his station operated in connection with rotary converters. This sub-station supplies power for lighting and railway purposes from the same transmission line, and it is only by the use of the battery that the fluctuations are kept within feasible limits. This battery is kept floating on the line to take up the fluctuations in load.

In the discussion of this paper the question was raised as to the cost of the storage battery. W. Owen Thomas said that the cost of the battery was about $100 per kilowatt at 1 hour rating. Answering some questions as to efficiency, E. L. Draffen said that the efficiency on this kind of work was 96 to 97 per cent., and that the manufacturers would maintain the battery for 5 per cent. of its initial cost per annum. He called attention to the advantages of using the battery in small direct-current plants, so that the generating machinery could be run for a short time fully loaded, supplying the peak load and afterward charging the battery, leaving the battery to take the light load the rest of the twenty-four hours.

Mr. J. A. White thought the efficiency given for the storage battery by Mr. Draffen was too high. If the battery was floating on the line, taking only the momentary peaks and never being fully discharged, an efficiency of 95 to 96 might be realized. The battery used to aid in carrying the peak load on the station only and discharged fully during the peak each day would probably give about 80 per cent. watt-hour efficiency; 75 per cent. being guaranteed by the manufacturing companies.

ELECTRIC METERS.

George S. Carson, of Iowa City, read a paper which was brief and to the point, on the plan of charging by meter. He condemned the flat rate still in existence in some plants and said that few realized how much the meter has to do with the success of the electric lighting business. The output of the company, which is paid for by the customers, is measured by the meter and, therefore, the earnings of the company are directly dependent upon its accuracy. The early meters were inaccurate, with heavy moving parts, but immense improvement had been made until the modern meter was a fairly satisfactory instrument. Meters should be tested upon receipt from the manufacturer, as their accuracy may have been damaged by their rough usage in transit. After a meter is put in operation it should be tested at regular intervals. The receipts per kilowatt-hour on a flat rate are usually about one-half what they should be. This does not mean that consumers will pay double their former bills when the change is made from a flat rate to a meter basis. Consumers which formerly wasted the current will begin to economize when put on meter, so that the output of the company will be reduced and the receipts on the whole increased.

In a plant which he had tested recently, which operates twenty-four hours per day, and is equipped with new meters throughout, he had found the switchboard output in a given period to be 18,450 kw-hours at the switchboard, and 13,806 kw-hours as measured by the consumers' meters. This represents a loss of 25.2 per cent. between the switchboard and the consumers. He thought the maximum demand system of charging with the aid of a maximum demand meter better than the plan of estimating a customer's maximum demand by the number of lights wired up. The latter system had the effect of restricting a customer in the number of lights he would install, while, if a customer was charged according to the indications of a maximum demand meter he would put in as many lights as he could use in various portions of the house, even though he did not ever expect to use them all at once, and thus his total consumption of energy would be greater than if fewer lights had been wired. This of course was to the company's interest.

Mr. Zahm, of Mason City, cited a case in his experience where 100 meters had been inspected by a company making a specialty of that business. These meters had been running for some time without attention; 97 per cent. of the meters were slow from 7 to 56 per cent. The 3 per cent. which were fast had been struck by lightning, which short-circuited some of the field turns, thus weakening the field and causing the meter to run fast. Now his company had gone over all its meters and established a laboratory for bringing in meters and testing them every six months systematically. Most of the trouble from slow meters is due to charred commutators and injured jewels and tips. He recommended that old jewels removed from meters be saved, as they could be recut after a sufficient quantity had been accumulated, so as to be as good as new, at a considerable price below the new jewels.

In response to a question as to where the 25 per cent. of energy went to in Mr. Carson's case where customers' meters registered 75 per cent. of the energy leaving the station, Mr. Carson replied that he thought 75 per cent. efficiency was considered very good for an alternating-current system, taking into account the line losses and core losses in the transformers.

Mr. Burt said that the results he had obtained in testing a large number of meters at Waterloo also showed that many meters were 55 to 60 per cent. slow. The majority of meters run slow on light loads. He considered the best meter one which could be adjusted accurately for a light load. He brings in his meters for testing. The cost of bringing in meters at regular intervals for testing was at first appalling, but a little calculation of the losses from slow meters showed that it paid.

Mr. Ferris said that at Somerville, Mass., the result of going the rounds of all meters and testing them resulted in 33⅓ per cent. increase in the gross revenue. He figured roughly that the loss of gross revenue would be about 33 per cent. in any station where meters were not tested.

DATA ON STEAM TURBINES.

Mr. J. M. Wilkinson read a paper descriptive of the Westinghouse-Parsons steam turbine and also presented some curves and data on efficiency, much of which has appeared before in these columns. One advantage claimed for this turbine is the large clearance between the moving and stationary vanes, which clearance permits the turbine to be operated without close adjustment. The only wear about such a turbine unit is the bearing wear, and the machine should, therefore, be very durable. Where condensed exhaust is used for boiler feed, the turbine offers pure boiler feed water, free from oil, since there are no valves or pistons which need lubricating. About 38,000 hp of these turbines have been built or are under construction in this country. The list of large turbine units given by him was astounding, even to those who have watched the progress of the steam turbine. He said that in no case had reciprocating engines been installed in plants after Westinghouse-Parsons turbines had been put in.

In response to a request from Mr. Carson to give the performance of a turbine on 120 pounds boiler pressure and 25 in. of vacuum, Mr. Wilkinson cited the nearest case he could find, which was on a 400-kw unit operating on 125 pounds steam pressure and 26 in. of vacuum. With a load of 580 hp the steam consumption was 15.21 pounds per brake-hp-hour. With the load at 457 hp the consumption was 16.36 pounds and at 326 hp the consumption was 17.89 pounds.

In answer to a question as to whether the governor of a turbine could be made to change the speed of the turbine by means of an electric motor controlled from a switchboard as in the case of a Corliss engine where it is desired to operate alternators in parallel, Mr. Wilkinson said that it was possible if thought desirable, but that the change in speed could be easily effected by hand. The cost of the steam turbine unit was given as about the same as that of a reciprocating steam engine unit. When asked for a comparison between the economy of a steam turbine and a gas engine, Mr. Wilkinson assumed that the turbine could be operated with two pounds of coal per hp-hour, while a gas engine would require 11,000 B.T.U. per brake-hp-hour, or about 1¼ pounds of coal. This was giving the gas engine the benefit of the doubt, however. He thought the economy of the gas engine and the steam turbine about the same under the best conditions. It would cost less to install the turbine.

The question was raised whether the reciprocating engine would go out of use. Mr. Wilkinson thought it would in the larger sizes. In the smallest sizes the reciprocating engine would show better economy. Replying to questions as to whether it did not require much greater investment in condenser to give the better vacuum considered desirable with a turbine, Mr. Wilkinson said that the same size of condenser as would be used with a corresponding size of reciprocating engine would give from 1¼ to 2 in. better vacuum with the turbine because of the few chances for air to leak into the turbine. As to spending money on a condenser to secure higher vacuum, that was simply a question as to how much would be gained by the higher vacuum. As more is gained by a higher vacuum on a turbine than on a steam engine, it naturally pays to spend more money in securing this vacuum on the turbine than on the steam engine.

LAMP TESTING.

Thursday morning's session was opened by Prof. L. B. Spinney with his paper on lamp testing. Prof. Spinney referred to the work which had been started at Iowa State College for the benefit of the central station men of the State. For some time the electrical department of this institution, under Prof. Spinney, has been prepared to test incandescent lamps for energy consumption and mean horizontal candle-power for the central stations of the State at the nominal rate of $1 per dozen. Prof. Spinney's paper was in the nature of a report of progress in this work. He said that comparatively few lamp tests by disinterested parties were to be found. Most of the tests heretofore published have been carried on by lamp manufacturers. The best efficiency of lamp to use is likely to be given too little attention. Whether a high or low efficiency lamp should be used will depend very much upon the cost of the current. If a station is operating with water power, so that the cost of supplying a few extra watts per lamp is small, a low-efficiency lamp may be advisable. In general, a high efficiency is desirable. There is an appreciable difference between lamps not only of different manufactures, but of the same make. He advocated lamp testing, at least in the rough, for all moderate-sized stations. He presented, by way of introduction, several curves characteristic of the behavior of incandescent lamps in general, showing how the resistance and watts per candle-power increase with age while the candle-power and efficiency decrease. He brought out the fact, sometimes forgotten, that the efficiency of a lamp depends on the voltage at which it is operated, and it may be made high or low efficiency by simply varying the voltage. He presented a number of shot gun diagrams showing the life and efficiency of 16 makes of lamps sent him for test. A large number of these lamps did not come within the efficiency and candle-power for which they were rated. While many of the results were not bad in themselves, they showed improper rating of lamps by the manufacturers. In response to questions as to whether results shown by Prof. Spinney were usual or simply exceptional cases, Prof. Spinney said that they were usual. Prof. Spinney advised the practice of making a rough photometer and wattmeter test of all lamps by the average central station, these tests to be supplemented and standards checked by laboratories with better testing facilities.

Mr. Carson said there was no trouble in getting lamps which would correspond with the guarantee when such testing was done by a central station company. Mr. Boyd said that he did not know of a single manufacturer sending out lamps of nominal 16-cp which would not vary at least 1 cp either way from this rating. No central station operated with exactly the same voltage at all points of the system. The advisable thing to do was to place lamps at the points best suited for their voltage. He considered that a voltmeter, indicating wattmeter, and a photometer were essential in the operation of any central station. These three instruments would cost about $250, and would prove a good investment.

SERIES ARC STREET LIGHTING.

M. A. Harrison, of Osceola, described a series alternating-current arc lighting system which his company had installed. This system is operated by two-phase, 1,100-volt generators. It has three circuits of 15, 20 and 25 lamps, respectively. He described the Western Electric regulator used to maintain constant current on these circuits. He said that the series enclosed arc lamp required more care in trimming than a series open arc. They had found that when the trimming was done by an inexperienced man there was likely to be trouble from nicking the inner globe so that air would be admitted and the life of the carbon shortened. A careless man would also fail to get carbons in line as they should be. They had found the average life of carbons to be 80 hours, although it was claimed that 120 hours could be run on one trimming. This was not realized in practice. Occasionally lamps would not pick up when the current was turned on to a circuit because of the high resistance of the contact between the carbon tips. This trouble could be overcome by momentarily increasing the current at starting. The cost per carbon on these lamps was 3½ cents per carbon and two 11/12 carbons were consumed per month per lamp. He favored metering current for street lighting in order to settle disputes regarding the number of hours lamps were out, as the city authorities were likely to claim more than the actual time.

MULTIPLE STREET ARC LIGHTING.

Rufus Lee, of Clarinda, read a paper on "Multiple Alternating Current Arc Lamps for Street Lighting." He stated his objections to the series system of arc lighting, namely, the high potential of the lamps, and the consequent danger to trouble men when fixing lamps, and the fact that a broken wire anywhere in the series circuit would put out the entire current. Consequently, he had installed alternating current enclosed arcs for street lighting, operating from constant-potential transformers. He had four circuits devoted to this work and they were operated from a two-phase generator, the arc circuits being provided with throw-over switches, so they can be placed on either phase. He had his arc lamps on a three-wire secondary distributing system, but did not advocate this, and was changing to a two-wire secondary system. In a few cases residences and incandescent lights were operated from the same secondary circuits, where for some reason it might not be feasible to have a regular commercial circuit.

Mr. Burt said that one thing about the multiple system of street arc lighting which he liked was the possibility of running different sizes of arc lamps. That feature he considered undoubtedly an advantage in some places.

EXPERIENCE WITH NERNST LAMPS.

Mr. G. C. Gardner, of Mt. Vernon, Iowa, had prepared a short paper on this subject, which was read by Mr. Greene. The experience of this company with Nernst lamps, which covered one year of operation, has been very satisfactory. These lamps require more attention than incandescent lamps, but his experience had shown that the lamps do all that is claimed for them in the printed matter of the manufacturing company. The quality of the light approached daylight, which made it a good lamp for dry goods stores. His customers liked it both on account of quality and the amount of light obtained for the money.

Mr. Greene said that his company was now supplying current for between 500 and 600 Nernst glowers. The experience had been satisfactory and customers were beginning to ask for the Nernst lamp. With the voltage regulation which they were now maintaining on the system, the maintenance of the Nernst lamps was about 0.6 cent per kilowatt-hour supplied to the lamp. Very close regulation was necessary.

Mr. Burt said that his experience with the Nernst lamp had been exceedingly varied. In a certain Catholic church, where it had been desired to install electric light without the expense of chandeliers, three six-glower lamps had been installed. The church people were very much pleased with the lighting of the church and delegations from other Catholic churches in the State had been inspecting the lighting. In his experience the greatest difficulty with the Nernst lamp is the burning out of the heaters, usually caused by neglect on the part of the customer to turn off the lamp when the glowers are burned out. The Nernst lamp is a good thing with which to compete with the Humphrey gas arc.

Mr. Greene said he was putting in three-glower Nernst lamps to do the same work as a four-burner Humphrey gas arc. The three-glower lamps consumed 270 watts.

Mr. Innes, of Eagle Grove, brought out the fact that a voltage much above normal for a short time would soon ruin the glowers, and that trouble in voltage regulation if the voltage was allowed to get high for a short time was likely to be followed by an unusual number of repairs on Nernst glowers. The Nernst lamp would stand about the same voltage variation as a 3.1-watt incandescent lamp.

Mr. Burt said, for the consolation of the electric light men, that the repairs on Humphrey gas arcs were by no means small, and that his company, which also owned a gas plant, charged $1 per month maintenance on one Humphrey arc installed for a customer and 50 cents each for additional arcs.

RENEWED INCANDESCENT LAMPS.

Mr. J. A. Innes, of Eagle Grove, gave a short paper on his experience with renewed incandescent lamps as compared to new lamps. While not presenting any definite figures, he said that the renewed lamps were similar in performance to many of the new lamps tested by Prof. Spinney, the performance of which was given in Prof. Spinney's paper. The cost of these lamps was about half that of new lamps. In discussing this paper, Mr. Innes said that a good photometer for rough testing could be purchased for about $14.

INCREASING THE OUTPUT OF LIGHTING PLANTS.

"The Best Method of Increasing the Output of Lighting and Power Plants" was the subject of a short paper by Mr. A. W. Zahm, of Mason City. He suggested a number of uses for electric current during hours when the lighting load is small, such as power for city and private pumping, the operation of refrigerating machinery, the use of heating devices and sign lighting. He considered the maximum demand system of charging good, because it tended to increase the consumption by long-hour customers. He made a low rate for opera houses and churches, because their maximum demand did not come at the time of heaviest load on the station, and in the case of opera houses, failure to make such a low rate might mean the installation of an isolated plant. He considered electric elevators an undesirable class of customers, and preferred to sell current to operate a pump for hydraulic elevators. He dwelt at length on the encouragement of sign lighting, mentioning the fact that very attractive signs are now made with low consumption of energy, and that in addition to local merchants, outside corporations sometimes spend considerable money in the illumination of large signs advertising some food product or the like. Thawing water pipes in cold weather was also a source of small revenue. Where a company mailed bills to its customers, it was a good plan to enclose a folder advertising some new electrical device with each bill each month.

On Thursday afternoon the discussion of Mr. Zahm's paper was taken up. The question was asked whether it would pay a central station to add a refrigerating plant. Mr. Zahm said that at Mason City there is a cold storage plant which also manufactures some ice for the use of the company owning the cold storage plant, in supplying its refrigerating cars. He did not advise central stations to go into the refrigerating business with ice as cheap as it is in Iowa, but private refrigerating plants made good customers. The manufacture of ice could only be engaged in profitably in connection with a cold storage plant where the investment in refrigerating machinery had already been made. He arranged with his cold storage plant customers that they should not operate during the winter peak load. These plants afford a continuous load in summer. Mr. McGee said that he had made a cold storage plant a very low rate with the understanding that he could shut them off during the peak load.

Mr. Carson asked how it would be possible to distinguish between store and sign lighting in rates. Mr. Zahm said that low-rate sign lighting should not be on at the peak, whereas store and store window lighting is. Mr. Burt thought that church lighting should only be the very highest rate. For example, a church might have as high as 300 lights, all of which are liable to come on at one time and to provide for which the company must keep a large investment idle except for the few hours the church was lighted. Mr. Carson agreed with Mr. Burt that the lighting bills of a church of this kind would not pay interest on the investment necessary to supply it. Mr. Zahm replied that the peak load is usually off by 7.30 P.M. Churches and opera houses are not fully lighted until about 8 P.M. He had an opera house using 650 lights in Mason City, which had never been turned on during the peak.

Mr. Greene figured that church lighting would come on during the peak of the residence load, but that, on account of the church attendance fewer lights would be used in residences, so that one would partly offset the other. Mr. Burt said that his company had earned about $625 the past winter thawing out frozen water pipes. This was done with the aid of a 10-kw transformer. The charge was $10 for the first hour on the job and $5 per hour after that. This charge was based on the value of the company's "professional services." It would cost several times that amount to do the job any other way. Mr. Smith, of Ackley, told of a man who had purchased a plating dynamo and a gasoline engine, which had been placed on a wagon and used to supply current wherever needed for thawing out water pipes. W. Owen Thomas said that considerable work in thawing out water pipes had been done at Sault Ste. Marie the past winter. They had a rough rule of using ½ volt per ft. of 2-in. pipe, increasing the voltage inversely as the square of the diameter and directly as the length.

OPERATION OF SINGLE-PHASE MOTORS ON LIGHTING CIRCUITS.

A paper on the above subject by Mr. W. A. Layman and Mr. Sparrow, which has previously appeared in the technical press, was read, in the absence of the authors, by Mr. W. Owen Thomas. This paper brought out the advantages of using the Wagner type of single-phase alternating-current motor on single-phase circuits. The curves of starting current and power given, showed the motor to be able to start with normal running current at considerably more than normal torque. These were from tests made by the Chicago Edison Company. Curves of cost prepared by the same company showed the cost of installation of the smaller sizes of single-phase motors to be much less than the cost of the same size polyphase motors.

After the reading and discussion of this paper Mr. Thomas, at the request of the association, gave a talk on the electric power development at Sault Ste. Marie, Mich., of which he is the engineer.

The question box, of which Mr. W. J. Greene, of Cedar Rapids, was editor, was presented to the Association in pamphlet form. A vote of thanks was passed to the Des Moines City Railway Company for the use of its car for a trip Thursday noon and to the supply men for the smoker tendered to the members Wednesday evening. The Association then went into executive session and elected the following officers for the ensuing year: President, W. L. Bowers, Davenport; vice-president, Austin Burt, Waterloo; secretary, W. S. Porter, Eldora; treasurer, Rufus E. Lee, Clarinda. Executive Committee—W. J. Greene, of Cedar Rapids; W. S. Carson, of Iowa City, and A. W. Zahm, of Mason City. The next meeting place will be Dubuque, Iowa, in April, 1905.

President W. L. Bowers.

Telephony In Nova Scotia.

Mr. W. R. Holloway, United States Consul-General, makes an interesting report on telephony in Nova Scotia:

"A new line of long-distance telephone, with 292 miles of copper wire, has been opened between Halifax and Sydney, the offices being equipped with the latest improvements. The reports of the Bell Company show that in the Province of Nova Scotia there is one telephone in use for every 88 inhabitants. In the city of Halifax there is one to every 27 persons, while in other towns the proportion is between 20 and 30. The report of the general manager of the Nova Scotia Telephone Company shows 790 miles of poles for their long-distance lines and 2,246 miles of copper wire. The total mileage of telephone wires in the Province is 7,136, and of posts is 791.

"The number of telephones in the Province is 3,260, of which 1,801 are in the city of Halifax. Last year the company transmitted 14,000,000 messages. The long-distance lines unite Truro, Amherst, Bridgewater, New Glasgow and Windsor-Sydney.

"The average number of calls per day, per telephone, in Halifax, is 11, compared with 7½ under the old system. Halifax answers daily 18,000 calls; the average per telephone is only 10, although some instruments go as high as 150 calls a day. The rates for conversations of three minutes between Halifax and points in Cape Breton country are each $1.25 in the daytime and 65 cents at night, between 6 P. M. and 8 A. M."

April Meeting of American Institute of Electrical Engineers.

At the regular monthly meeting of the American Institute of Electrical Engineers held on Friday evening, April 22, two papers were presented, one by Mr. David B. Rushmore on the "Mechanical Construction of Revolving-field Alternators," and another by Messrs. H. M. Hobart and Franklin Punga, entitled "A Contribution to the Theory of the Regulation of Alternators."

Mr. Rushmore, in his paper, gave information in detail concerning the construction of revolving-field armatures, under the head of yokes, laminations, clamps for laminations, slots, armature winding, ventilating space blocks, shields, rims, arms, hubs, field coils, pole shoes and collector rings. The paper, which is profusely illustrated, does not admit of abstract, but in its original form will be found of much value as presenting the present status of the construction of revolving-field alternators, with a discussion of the various differences in design.

The paper by Messrs. Hobart and Punga described a new method for the predetermination of the characteristic curves of alternators with special reference to regulation. The paper is accompanied by numerous curves, and abundant data are given for use in applying the method. The authors start with the assertion that the change in the voltage of a constantly-excited generator when its load is varied in nature or amount, is chiefly occasioned by the magnetic flux set up by the current in the armature winding and linked with the turns constituting the winding. This flux is classified according as the flow in one or the other of three paths as follows: In the first path the lines never emerge from the armature and consist of those which cross the armature slot from side to side, and those which are linked with the end connections. In the second path the lines emerge from the armature and cross the air-gap toward one end of the pole shoe, and after passing along the pole shoe return across the air-gap to the armature from the other end of the pole shoe. In the third path the lines, after emerging from the armature, traverse successively the air-gap, pole shoe, magnet core, yoke, adjacent magnet core and pole shoe; and after again traversing the air-gap re-enter the armature.

On the basis of this analysis the authors proceed to develop a theory, and a table is given which shows a close agreement between calculation and experiment in the case of seven single-phase and eleven three-phase machines.

The paper in referring to the specification of regulation, says it is exceedingly difficult, even with the best wattmeters and other measuring instruments, to demonstrate the presence or absence of a slight difference of phase or to measure it, although such a slight phase difference has a great influence on the regulation. Furthermore, for tests with unity power factor a certain fall in speed is difficult to avoid in throwing on the load. It is stated that a very desirable step would, therefore, be the introduction of the percentage inherent regulation at zero power factor as an important criterion of design, and the paper discusses a number of factors which in this case it would be necessary to specially consider since they may affect the inherent regulation at unity power factor without impairing the inherent regulation at zero power factor.

The discussion of papers was participated in by Prof. C. A. Adams and Messrs. B. A. Behrend, W. L. Waters, Gano S. Dunn and Dr. F. A. C. Perrine. Prof. Adams criticised the use in the paper of Messrs. Hobart and Punga of the average in connection with leakage reactance. He took exception also to the statement that similar methods previously suggested did not yield good results, and referred to a method which he had devised which gives quite as good accuracy as that of the authors'. In this method the whole magnetomotive force is considered as one, and its space direction, not the phase, is employed in such a manner that it takes account of the shift from the central full-phase position. The chief approximation is the position of the field magnetomotive force and the armature magnetomotive force. Recently the method was applied to a closed-coil ring armature in which the three-phase connection gave a three-belted winding, a single belt occupying 120° instead of 60°, as in the ordinary three-phase machine. This makes the application of the armature magnetomotive force more complicated, but the results came out closely.

Mr. B. A. Behrend said that the problem considered is so complex and intricate and there are so many factors to be taken in account, that it does not admit of general solution. He criticised severely the specification of regulation on a power factor of unity. In large machines a unity power factor can never be obtained. If tested with a water rheostat, a leading current is introduced owing to the electrostatic capacity of water resistance. He considered that the regulation should be determined at zero power factor. By using two machines, one as a synchronous motor and one as a generator, this can be done, and it can also be done by splitting the field with perhaps less accuracy. Mr. W. L. Waters, in a communication, criticised some of the assumptions of the authors, particularly with respect to the factor of cost magnetization. He believed that Mr. Hobart's method, if considered an empirical method, will probably be able to give good results in practice. As to the calculation of the short-circuit current of an alternator, he considered this cannot be accepted as a test of any theory, the real test being to calculate the regulation on inductive loads. He thought, however, that the authors are doing good service in again emphasizing the advisability of guaranteeing regulation upon zero power factor rather than on non-inductive load. The most important point in the theory is the way in which account is taken of increased leakage caused by the back ampere-turns on the armature, the paper presenting for the first time any method of calculating the effect.

Prof. Adams took exception to the last statement, saying that the method used by Messrs. Hobart and Punga was described in detail by himself two years ago in almost exactly the same form. Mr. Behrend called attention to the fact that Prof. Blondel, some four years ago, published a theory based on tests made by Mr. Behrend on alternators, which was essentially the same as that just referred to. Mr. Gano S. Dunn pointed out that some of the criticisms were due to the evident misreading of the paper of Messrs. Hobart and Punga, and agreed with Mr. Behrend that engineering and designing of the kind to which the papers of the evening referred are not a science but an art. A consideration of innumerable factors is required, many of which are human rather than mathematical. Mr. Dunn mentioned the desirability of a construction whereby the bursting strain would be taken by the armature or revolving ring as an annulus and not by the spokes. Mr. Rushmore, referring to the remarks made concerning the difficulty of predetermined alternator regulation, said that when we get down to actual figures the regulation of alternators can now be estimated as closely as is desired. Referring to the matter of the strains and revolving armature, Dr. Perrine cited the case of a revolving field which is constructed with a smooth uniform rim bolted to spokes that had extended ends and with a spider construction that was not continuous. The rims are fastened to a spoke that is capable of extension and the former are so arranged as to produce the elastic spoke referred to by Mr. Dunn.

British Telegraphs and Telephones.

The Postmaster-General recently asked Parliament for $15,000,000 for the extension of the government's telephone system. The Postmaster-General also admitted in debate that the government was negotiating with the National Telephone Company for the purchase of their business.

The charge for telephones in London is £5 per year, plus 1d. per call for inner London, and 2d. per call for outer London, or an average of about £8 per year. The London system netted last year only £6,155, allowing nothing for an interest and depreciation charge of £60,780.

The government's telephone and telegraph systems in Great Britain last year cost £267,000 more than it earned, allowing for £167,000 received from the National Company as a bonus for doing business. The government has about £30,000,000 invested in telephones and telegraphs, the annual interest upon which is about £1,200,000. In other words, government control in this case costs some $6,000,000 per year.

A correspondent of the London *Times* says: "If we had a telephone service in London such as they have in New York or in any of the other cities of America, I venture to say there would, without question, be an enormous saving of time, temper and money; but so long as people are willing to tolerate the execrable service with which we in London are at present afflicted, so long will the authorities take no steps to improve the service."

Spring Meeting of the Magnetic Club.

The spring meeting of the Magnetic Club was held at Hotel Spalding, New York, on the evening of April 21, and in point of attendance and the prominence of the guests it was probably the record meeting of the club. The affair was planned on a liberal scale and successfully carried out, everyone present evincing that spirit of good fellowship for which the club is justly famous.

The Magnetic Club is essentially an organization of New York telegraphers, but a happy thought occurred to President Francis W. Jones in laying his plans for this meeting, and that was to get the telephone men interested in the club so that those connected with the two great organizations might meet together occasionally on a social plane and become better acquainted with one another. The result was that the meeting had a distinctively telephonic character, and the hospitality of the club was generously bestowed upon the many telephone officials present. The officials of the two great telegraph companies were also present to do honor to the telephone guests.

The guests of honor included Messrs. F. P. Fish, president of the American Telephone & Telegraph Company; E. J. Hall, vice-president, and Thomas D. Lockwood, electrician; W. D. Sargent, J. C. Reilly and B. Gherardi, Jr., vice-president, general manager and electrical engineer, respectively, of the New York & New Jersey Telephone Company; U. N. Bethell, vice-president of the New York Telephone Company, and C. H. Wilson, general superintendent of the same company. Other well-known gentlemen present were Col. R. C. Clowry, president and general manager of the Western Union Telegraph Company, and J. C. Barclay, assistant general manager; Clarence W. Mackay, president of the Postal Telegraph and Commercial Cable Companies, and G. G. Ward, vice-president and general manager Commercial Cable Company; Col. A. B. Chandler, W. H. Baker and C. P. Bruch, of the Postal Telegraph Company; Melville E. Stone, general manager of the Associated Press, and H. L. Shippy, treasurer of the John A. Roebling's Sons' Company. Many other persons well known in the telegraph and telephone fields were present, there being about 250 in all.

After the dinner President Jones, in a few well-chosen remarks, introduced President Fish, of the Bell Telephone Company, who responded to the toast, "The Telephone." Mr. Fish evidently kept it in mind that the gathering was more in the nature of a social function than one assembled to listen to and discuss statistics and business problems, so he refrained from touching upon such matters. His remarks were confined to pleasantries regarding the telephone and the telegraph, and his sallies kept the company in good humor.

Mr. U. N. Bethell was next called upon to respond to the toast, "Professor A. G. Bell." The speaker paid an eloquent tribute to the character and work of the great inventor. He referred to Prof. Bell's steadfast faith in the future of the telephone, while capitalists, in the early days, looked upon it as a mere scientific toy. These capitalists, for whom Prof. Bell was developing some other inventions, actually placed a guard over the inventor to prevent him from wasting time on the telephone. By patient persistence, however, Prof. Bell demonstrated that he was right.

Persistent workers, said the speaker, are of more worth to the world than brilliant minds, and, combined, their efforts are irresistible. Mr. Bethell then reviewed the development of the telephone from its conception in the mind of Prof. Bell, in 1874, through the trying period of its growth up to the time when it became a practical every-day thing. He read extracts from a letter written by Prof. Bell in 1878 to show that at the very outset the inventor had a clear conception of the possibilities of the invention. The letter outlined a proposed method of running individual lines to a central point for interconnection, thus laying the foundation for what is now known as the telephone exchange. He even suggested the advisability of laying the wires underground and running them in cables.

"The telephone art," the speaker continued, "is changing so rapidly that no one dare take an extended vacation for fear that when he came back he would not understand things." Mr. Bethell treated his subject in a masterly manner and his address was listened to with the keenest attention and interest.

Other toasts responded to were: "The Telegraph," by Mr. C. P. Bruch, who was the first president of the Magnetic Club; "Old-Time Telegraphers," by Col. A. B. Chandler; "Cables," by George G. Ward; "The Press," by Melville E. Stone, and "The Magnetic Club," by John R. Van Wormer.

President Jones read a letter from Prof. Bell, in which the writer expressed regrets at his inability to be present at the meeting, owing to a prior engagement, which he had hoped to postpone, but found, at the last moment, that he could not break.

The speaking was interspersed by excellent vocal and instrumental music, an exhibition of ventriloquism being an interesting feature of the programme. Over the doorway of the banquet hall were placed two electric signs, one bearing the word "Hello" and the other the well-known telegraph signal, "O. K." These were used effectively during the addresses in flashing out their expressions by way of appreciation and approval at striking points in the remarks of the different speakers.

The menus contained a very fine three-quarter figure etching of Prof. Bell, made from one of his most recent photographs. It was an artistic piece of work and was carefully preserved by all as a souvenir of the occasion.

Electric High Pressure Fire Service in New York.

Mr. N. Hill, chief engineer of the Bureau of Water Supply, New York City, has made a report on the use of high-pressure fire service for the Borough of Manhattan, and Mr. I. M. de Varona has reported as to Brooklyn. The reports have been approved by the Board of Estimate and Apportionment, and call for an appropriation of $5,425,400, which the Board of Aldermen have voted for the purpose. The idea is to provide both fresh and salt water for fire and street flushing purposes. As between the three powers—steam, gas and electricity—the last is decidedly favored. Three pumping stations are proposed in the area of one-tenth of Manhattan, comprising the dry goods section and the East Side lower tenement district. Mr. Hill presents the following data as to electric plants compared with gas:

The mechanical efficiency of the gas and electric plants is approximately the same. In comparing the use of gas and electricity as the probable source of energy it may be well to present the following points in favor of electricity: 1. Economy in first cost of machinery and buildings. 2. Economy in space necessary for installation, thereby reducing cost of land required. 3. Economy in cost of wages, maintenance, repairs and renewals. 4. Simplicity.

The relative cost of power cannot be stated with accuracy until the price for which gas can be had is determined. Following is a statement of the comparative cost of one pumping station operated either by gas or electricity, an estimate of the probable operating expenses and fixed charges per annum, a similar summary for the three stations and an estimate of the total cost of high-pressure fire service complete:

COST OF ONE PUMPING STATION.

	Electric.	Gas.
Number of units in station	4	6
Capacity in million gallons per hour	1	1
Estimated number of hours plant will be in operation per year	80	80
Cost of motors and turbines, including piping, foundations, switchboard and wiring and cables	$255,000	......
Cost of gas engines and pumps, including piping, foundations and auxiliaries, complete	......	$448,000
Cost of buildings, foundations and land	90,000	270,000
Total cost	$345,000	$718,000
Cost of wages per annum	7,650	18,150
Cost of gas per year	......	17,000
Cost of electricity per year at 4½ cents per kw-hour	13,200	......
Cost of oil, waste and supplies per year	300	300
Cost of repairs per year	2,400	3,600
Total cost of operation	$23,550	$39,050
Interest and depreciation	26,710	55,000
Refunding sinking fund	11,500	27,000
Total cost per annum	$61,760	$121,050

Cost of Three Pumping Stations.

	Electricity.	Gas.
Cost of three stations	$1,035,000	$2,154,000
Operating expenses and fixed charges per annum for three stations	185,280	363,150

Summary of Total Cost.

	Electricity.	Gas.
Pumping stations	$1,035,000	$2,154,000
Mains for distribution system, complete, with gate valves and hydrants	2,107,000	2,107,000
Telephone system	150,000	150,000
Total cost	$3,292,000	$4,411,000
Add 10 per cent. contingencies	329,200	441,100
Add 10 per cent. superintendence	329,200	441,100
Totals	$3,950,400	$5,293,200

The pressure at the station is proposed to be 300 pounds and the minimum pressure at the hydrant 200 pounds. Mr. Hill counts apparently on drawing current supply from the mains of the Manhattan central stations and says that the three pumping plants would require 15,000 hp working at their full capacity. The data for Brooklyn follow the same general lines.

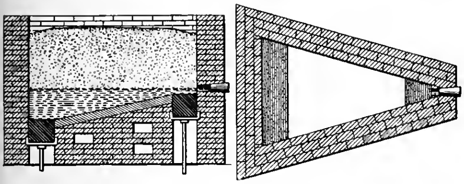
Recent Electrochemical Developments.

CALCIUM CARBIDE FURNACE.

Formerly the object of electric furnaces was to produce as high a temperature as possible; now the tendency is manifest to design furnaces in such a way as to always have the temperature under exact control. In some cases (in those in which the charge may give different products at different temperatures) it is evidently important to provide as uniform as possible a temperature throughout the furnace. Some of Mr. Acheson's recent furnace designs belong to this class.

In the manufacture of calcium carbide, the problem is a different and simpler one, and the main object of a large number of furnace constructions disclosed in seven patents granted on April 19th to Messrs. W. S. Horry and E. F. Price, of the Union Carbide Company, of Niagara Falls, is to design a furnace with a non-uniform distribution of the generated heat. While in general the temperature in the furnace must be sufficient for the formation of carbide, yet it is only near the tapping hole, where an extremely high temperature should be produced, sufficient to render the calcium carbide fluid at that particular place.

Several principles are made use of for this purpose. In several designs, the cross-section of the charge is diminished gradually towards the tapping hole, so that the current density is highest at that point. This is shown in Figs. 1 and 2, which represent a vertical and horizontal cross-section, the tapping hole being at the right.



FIGS. 1 AND 2.—HORRY AND PRICE ELECTRIC FURNACE.

In other designs a superposition of currents is made use of, for instance in the following manner: In a stack furnace a single negative electrode is provided at the bottom, and here is also the tapping hole. Several positive electrodes are provided at different heights of the furnace. If, through each of them direct current is sent into the furnace, which leaves it through the negative electrode at the bottom, it is clearly seen that the current passing through the charge becomes gradually greater as the bottom is approached.

Two of the patents refer to the use of polyphase currents for a furnace of circular cross-section. It is proposed to use a great many phases and to distribute electrodes at equal intervals around the circumference, each electrode corresponding to one phase. If a central electrode is provided which is connected to the neutral point of the polyphase system, then the temperature becomes highest near the center of the furnace, and the tapping hole is, therefore, provided at that place.

COPPER EXTRACTION BY ELECTROLYSIS.

A patent granted on April 19th to Mr. S. Laszynski, of Kielce, Russia, refers to the use of a tight envelope of fabric around an insoluble anode for the purpose of preventing anodic oxidation of the cations. For instance, in a solution containing ferrous sulphate the anodic reaction at the anode would be the oxidation of ferrous salt to ferric salt. In an electrolytic process of extraction of copper ores containing iron, this reaction would have the disadvantage that the ferric sulphate, while formed at the anode, might come in contact with the cathode and redissolve the deposited copper by local action. If a porous fabric envelope around the anode is used, the anodic reaction is essentially the formation of sulphuric acid and no ferric salt is formed since the ferrous sulphate does not come into contact with the anode. This envelope, therefore, acts like a diaphragm. The author states that in this way the direct electrolysis of copper baths containing iron is possible with a nearly theoretical efficiency, even if they contain twice as much iron as copper, since the iron remains in the state of the wholly unoffensive proto-sulphate of iron and with no corroding action of any kind.

MISCELLANEOUS.

A patent granted to Messrs. W. J. Joly and J. H. Joly, of San Francisco, Cal., refers to details of mechanical construction of apparatus for the electrolytic extraction of metals from slimes, sands and solution. The apparatus comprises essentially a sluice box and electrodes swinging on horizontal axes and adapted to float on the surface of a stream passing through the box.

A patent was granted to Mr. J. Bijur, relating to the manufacture of open-work structures for storage battery plates. The primary object is to enable strong and efficient plates to be made by embracing a number of individual elements having interstices—as, for instance, grilles or pastilles—with molten metal, to form the completed structure, although the elements may have any desired form. The interstices of the individual elements are first filled with a soluble material, like soda-ash, to prevent them from becoming filled with molten metal. The elements are then assembled in the desired arrangement with channels or spaces between them, and the channels filled with molten metal to embrace the elements to form the completed structure. The soda-ash is then removed to leave the finished open-work plate.

A patent granted to Mr. A. V. Meserole, of New York City, refers to the construction of a light and durable storage battery plate in which the mechanical strain is distributed by a new arrangement of the electrodes and their supporting devices. A supporting bar is provided with depending tubular members through which bolts are threaded. A stirrup plate is mounted on the bolts and tablets of active material encircle the tubular members and rest upon the stirrup plate.

A patent granted to Mr. J. H. Reid, of Newark, N. J., relates to his "gas battery," which has been noticed before in these columns. The object of the present patent is to obtain a circulation of the electrolyte so that "the bubbles in the electrolyte formed by the action of the gas or gases in the development of the electric current may be broken up and the inert gases allowed to escape."

New Telephone Patents.

A WELL-DESIGNED DESK STAND.

While the tendency on all sides has always been toward the simplification of the telephone subscriber's set, it is apparently but recently that any great effort has been made to make the internal workings readily accessible. In receivers this effort has resulted in some designs which when considered from this standpoint approach perfection, and now that similar good work is being done on the desk stand set is evidenced by a patent just issued to Mr. H. P. Claussen, of Chicago. In this stand the removal of a single screw from the base plate allows of the whole stand being knocked down. The base comes off and then the tubular upright may be slipped down over the cord, entirely exposing the working parts. These latter are all mounted upon a strip of insulating fibre which is secured to the transmitter bracket piece. A good idea of the arrangement of the parts may be obtained from Fig. 1, which shows a partial sectional view, and a side view of the transmitter with those parts integrally connected thereto. Mr. Claussen has assigned his patent to the American Electric Telephone Company.

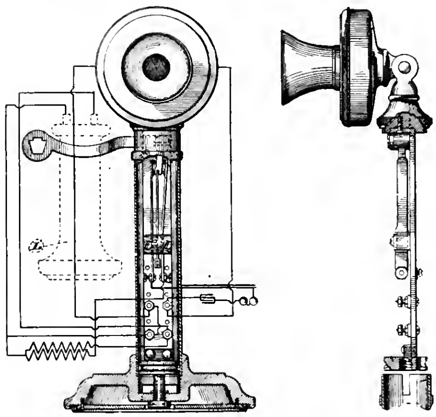


FIG. 1.—CLAUSEN DESK TELEPHONE.

POCKET MICROBE CATCHER.

Of all the numerous antiseptic devices for telephone transmitters thus far brought out, that which has recently been patented by H. S. Thompson, of Waterbury, Conn., seems to have most points in its favor. This is a device put up to be carried in the pocket and differing little in size and shape from a watch. The case is of a diameter to just fit over the transmitter mouthpiece, a screen of gauze being stretched across it. Each cover carries a pad which contacts with the gauze whenever the case is closed. These pads are wet with

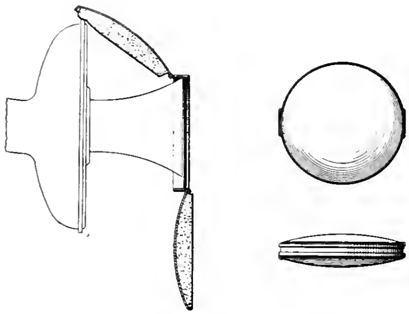

FIG. 2.—THOMPSON ANTISEPTIC ATTACHMENT.

antiseptic solution. Fig. 2 shows the case closed and in position for use.

TRANSMITTER.

W. L. Wilhelm, of Buffalo, has had issued a patent for a special type of casing for a double-diaphragm transmitter. The casing is of ellipsoidal shape, the mouthpiece surmounting one of the smaller ends. The diaphragms are in a plane parallel to the long axis and the sound waves are conducted to them through two curved tubes, which combine into a threaded ring as they approach the mouthpiece. This ring screws into the casing.

SELECTIVE SYSTEMS.

Two selective systems for party line signalling complete the list of patents. Both these are step-by-step systems, the one most simple and the other of a complexity apparently fatal to its success. The former is the work of Albert Meinema, of Chicago, while P. H. Fisk, of Clay, Iowa, is the inventor of the latter.

In Mr. Meinema's system a rotating ratchet wheel is interposed between the hook switch lever and its springs. When the wheel is in the proper position the bell of that station is connected to the line. The further actuation of the hook switch springs into the talking connection also depends on the position of this same wheel, and thus a lock-out for non-wanted stations is provided.

National Electric Light Association.

Mr. Charles H. Hodskinson, chairman of the committee on hotel accommodations for the twenty-seventh convention of this association, to be held in Boston May 24, 25, 26 and 27, reports that an unusually large number of rooms have already been assigned to members. The placing of this matter in the hands of a committee to whom all applications for rooms are referred, will undoubtedly result in better satisfaction for members of the association, as they will be cared for first and will not be obliged, should they be a little late in deciding to attend, to make the best of such accommodations as were left after non-members have been provided for, as has often happened in former years.

In addition to the New England Passenger Association and the Trunk Line Association, the secretary reports that the Central Passenger Association and the Southeastern Passenger Association have made a rate of a fare and a third for the round trip, from all points throughout their territory for delegates and friends attending the twenty-seventh convention at Boston. Mr. Frank L. Perry, of the *Western Electrician*, has consented to take charge of transportation matters for Chicago and vicinity, and proposes to arrange for a special train to bring delegates to the convention. Mr. Perry's well-known energy ought to insure the success of this effort.

The following are among the recent additions to the membership of the National Electric Light Association: Active—Connecticut, South Manchester, South Manchester Light, Power & Tramway Company. Indiana, Marion Light & Heating Company. Massachusetts, Leicester, Rawson Light & Power Company. Mexico, Monterey, Monterey Light & Power Company. New York, Little Falls, Herkimer County Light & Power Company; Lockport, Lockport Gas & Electric Light Company. Washington, Olympia, Olympia Light & Power Company. West Virginia, Bluefields, East River Electric Company. Associate—Indiana, Jonesboro, India Rubber & Insulated Wire Company. Iowa, Keokuk, Garton-Daniels Company. Missouri, St. Louis, Wagner Electric Manufacturing Company; St. Louis, The Emerson Electric Manufacturing Company. New York City, Sanderson & Porter, 52 William Street; Holophane Glass Company, 15 East Thirty-second Street; The Electric Carriage Call Company, Incorporated, 328 West Forty-first Street; New Brighton, C. W. Hunt Company.

The Cumberland Telephone Company in Evansville, Ind.

The Cumberland Telephone Company, of Evansville, Ind., has made the city council a proposition with a view to settling the controversy between the city and company and end further litigation.

The terms proposed by the Cumberland Company are: First, to submit the question of telephone rates to a committee of arbitration. The Cumberland agreed to Major Gilchrist, one of the attorneys for the so-called municipal telephone; Col. R. K. Dunkerson, a director of the municipal company, and A. C. Rosencranz as the committee. In case this committee was not satisfactory to the council it is proposed that the city make one nomination, the company another and the two to select a third. This committee may hire an expert accountant, who can examine the books of the Cumberland Company, both in Evansville and Nashville. The only stipulation is that the committee be of such a character as to command the confidence of the people of the city.

Second, growing out of the first proposition, the committee is to determine whether the city should be given a bonus by the company or pay an annual stipend. The entire matter of rates and compensation is to be left to the arbitration committee.

Third, the agreement shall be entered upon the journal of the United States District Court of Indiana and have the effect of decree of court. In effect it would be a permanent injunction against the city from removing the poles and wires of the Cumberland Company.

Subsidiary considerations discussed at the meeting between the Mayor and representatives of the company were:

First, a suggestion that the Cumberland Company pay the cost of the city in defending the injunction suit brought by the Cumberland against the city; that the Cumberland pay the attorney fees and cost of preparing the case, though the amount was not discussed. The cost of defending the Richardson suit was not mentioned.

Second, while it was not requested by the Mayor or offered by the company, there was an informal suggestion that the Cumberland assume the losses of the defunct Municipal Telephone Company. It is understood this amounts to nearly $7,000.

Briefly stated, the Cumberland offers to leave to arbitration of a committee of Evansville business men the rates to be charged and the compensation to be given the city. Their finding is to be made a record of court and in return the Cumberland is to have practically a perpetual franchise. The company also offers, aside from any award ofthe arbitration committee to pay the cost of the recent suit and perhaps to recompense the losses of the municipal telephone fiasco. No exclusive franchise is or could be asked for. Other companies may be admitted to the field. Action upon the proposition of the Cumberland Company rests with the Mayor and council.

Volunteer Russian Telegraphers.

The Czar of Russia has accepted the offer of the senior class of the Electro-Technical School at Odessa to serve as volunteer telegraphers in Manchuria. These volunteers will have charge of the wires along the Manchurian line.

Prices of Radium in France.

It is stated that the makers of Curie's radium can furnish it in several different degrees of purity, and therefore in varying intensities. A price list is given for radium and barium chloride, except the lowest activity, which is a compound of radium and carbonate. The minimum quantities sold as well as the current prices for radium are stated. The prices vary from $1.50 per gram for 40 activity to $1,250 per gram for 20,000 activity. The prices, it is stated, are advancing from week to week, owing to the enormous demand.

CURRENT NEWS AND NOTES.

SEOUL ELECTRIC PLANT BURNED.—Fire destroyed the imperial palace at Seoul, Corea, April 15. The new electric lighting plant was also destroyed.

VERMONT ELECTRICAL ASSOCIATION.—This association will hold its next meeting in Montpelier, September 21 and 22 next. Mr. C. C. Wells, Middlebury, Vt., is secretary.

WIRELESS IN SOUTHWEST AFRICA.—Germany, which is having serious trouble with the natives there, is sending men to German Southwest Africa equipped with wireless telegraphy apparatus and balloons to be used in the campaign against the Herreros.

CANADIAN ELECTRICAL ASSOCIATION.—The next annual meeting of the Canadian Electrical Association will be held in Hamilton, Ont., June 15, 16 and 17 next. A series of interesting papers has been arranged for. Mr. C. H. Mortimer, Toronto, Ont., is secretary.

STATE ELECTRICAL ENGINEERS.—The New York State Civil Service Commission among examinations to be held May 21, 1904, will include positions for electrical engineers in State hospitals and institutions. Application must be made to the chief examiner, C. S. Fowler, Albany, before May 16.

ELECTRIC AUTOMOBILES.—A cable dispatch from Paris of April 23 says: "Electric automobiles bid fair to eclipse petroleum vehicles for town locomotion. Manufacturers are selling them as rapidly as they can produce them. At the Société Française des Electromobiles it is almost impossible to hire a machine." France usually leads the way in these things.

BUFFALO TO CLEVELAND.—The De Forest wireless system is now in successful commercial operation between Buffalo and Cleveland, an air distance of 170 miles, most of which is overland and part across Lake Erie. The poles are 195 ft. high, with 11 wires for sending and 3 for receiving. Dr. Lee De Forest has had personal charge of the equipment.

WAR PENSIONERS.—An article on "Our Enormous Pension Roll," by Mr. R. L. O'Brien, in the *World's Work* for May, contains some very interesting and curious data. It tells of one man who drew a pension for total deafness, on the certificate of an examining committee, and was found in active charge of a telephone switchboard. The State of Georgia at one time had so poor an opinion of lightning rods that it did not grant its Confederate veterans the usual exemption from license in connection with their sale.

REUNION OF POSTAL TELEGRAPH OFFICIALS.—A reunion of officials and heads of departments of the Postal Telegraph-Cable Company from all over the country will be held in New York May 24 next. The gathering is for the purpose of exchange of ideas and experiences for the general good of the service. This meeting will also celebrate the sixty-fourth anniversary of the invention of the telegraph. It is proposed to hold these meetings annually hereafter. The last general convention of officials was held ten years ago.

ELECTRICITY IN PARAGUAY, S. A.—Mr. J. N. Ruffin, United States Consul at Asuncion, Paraguay, says: "An electric lighting plant has been established here, though the lamps have not yet been put up. If the enterprise is successful it will be extended so as to supply electric motor power, the introduction of fans, etc. It seems as if the electric light will be a success, and in view of this some persons have applied at this consulate for catalogues of electric lamps, fans, etc., accompanied with export prices, if possible written in Spanish."

PAIN-KILLING RADIUM.—Doctor Darier, of Paris, describes a case of cancer of the face which, through application of radium, had been rendered painless. Similar results have been obtained by other noted experts. He has also found quick and pain-killing effects of radium in certain diseases of the eye. The influence of radium upon the motor-nerve centers he considers of still greater importance. In two cases of nervous spasms—which occurred three to four times a week—weak radium preparations were applied to the temples for two or three days, when the spasms ceased. In a case also of presumptive inability of motion, caused by nervous debility, radium effected a complete cure within three days—probably, however, through suggestion. In acute facial paralysis of entirely new origin, radium effected a cure in one day.

WAR RULES FOR WIRELESS.—A cable dispatch to the New York *Times* of April 21 says: "The British Government is giving careful consideration to the Russian edict in reference to the use of wireless telegraphy by war correspondents in the Far East. Whether it has made any representations to Russia in the nature of a protest against her line of action, it is impossible to state at this moment; but if such representations have not yet been made, it is quite likely that they will be made. At any rate, Lord Lansdowne is fully impressed with the view that the attitude Russia has assumed as to wireless telegraphy is unjustifiable and altogether absurd. The only correspondent directly affected by the Russian note is the correspondent of the London *Times* and the New York *Times*. Lord Lansdowne, who fully understands the methods and status of this correspondent, unqualifiedly repudiates the Russian contention that he is in the same category as a spy, and condemns the purposes Russia entertains in respect to the correspondent, his chartered vessel, and his wireless telegraphy apparatus."

ELECTRICITY IN JAVA.—Mr. B. S. Rairden, United States Consul at Batavia, Java, informs us that the only city in Java with electric lighting is Batavia. The harbor of that city, Tandjong Priok, also has its own lighting station, owned and operated by the government. There are three telephone exchanges in Batavia and a system for long-distance work connecting the city with Samarang and Soerabaya (Intercommunale Telefoon Maatschappij). There is also another telephone exchange—Batavia-Soekaboemi Telephone Company—which connects Batavia with Buitenzoig and Soekaboemi. The telephone systems have a number of American instruments in use, and are using more American material lately, the appliances and material being found superior by the Netherlands-India Telephone Company. The eight miles of trolley in Batavia were equipped by Siemens & Halske, of Berlin, who also put in the electric power plant, which operates the government opium factory. The street railway company is known as the Electric Tram Company, or Electrische Tram Maatschappij. There are two electrical supply houses —Maintz & Co. and Carl Schlieper.

A NEW COLOR QUESTION.—According to veracious advices from Philadelphia, "Dr. Thomas R. Eldridge, of 1639 North Broad Street, for several months has been making a series of experiments, the aim of which has been the transforming of negroes into whites. There was a fire at the surgeon's establishment last Sunday and the apparatus with which the experiments were being carried on were destroyed. As a consequence there are half a dozen negroes who are guessing hard. Dr. Eldridge was doing the bleaching by throwing an X-ray light through radium, thus destroying the coloring pigment of the skin. Several negroes who had undergone treatment are now partly white. With the destruction of the electrical appliances the work of completing the transformation is halted. The patients are, therefore, left in a state of what might be termed dermatological suspense. It will be several months before duplicate apparatus can be built. Meantime, Dr. Eldridge does not know what will become of the blacks. He does not think that the whitened parts of the skin will become black. All he knows just now is that there are a half dozen unhappy negroes in Philadelphia."

EXTRACTING NAIL FROM BODY.—According to a statement from Salt Lake City, a nail has been drawn from a point close to the heart of Louis E. Cherry, aged 16 months, by an electric magnet. The child swallowed a nail two weeks ago. Experiments on a dog showed it to be impossible to extract a nail with the usual instruments. A long curved piece of steel, attached to a powerful electromagnet, was pushed down the windpipe, and as soon as the current was turned on the nail became attached to the steel and was withdrawn.

WIRELESS IN WAR.—At a meeting of President Roosevelt's Cabinet last week a discussion was had, it is credibly reported, looking to the control by the government of wireless telegraphy. The opinion was expressed that it would be desirable, if not, indeed, absolutely necessary, for this government to control, at least in a supervisory way, the operation of wireless telegraphy, particularly along the coast. It was pointed out that, in the event of a war with a foreign nation it might be necessary in defence of the nation for officers of the United States to have charge of these stations, as a means of assurance to the government that no communication was established with vessels of the enemy's fleet, and that the system was not employed to the detriment of United States interests.

SIBLEY JOURNAL OF MECHANICAL ENGINEERING.—The contents of the current issue of the *Sibley Journal of Mechanical Engineering* belie its title, two of the three papers contained treating of electrical subjects. Prof. H. J. Ryan contributes an interesting paper entitled "Some Problems in Electrical Engineering Due to Conductivity of the Atmosphere," in which, after pointing out the gravity of the problem of atmospheric conductivity in connection with high-voltage transmission work, he gives the results of experiments to determine the variation of such conductivity in the case of conductors in an undue pressure. It is shown that air under a compression of 150 pounds per square inch has an insulating strength at least ten times its normal strength. The second paper referred to is by Mr. Bion J. Arnold, and describes the Arnold electro-pneumatic railway system in detail.

ELECTRIC ROAD UP VESUVIUS.—Visitors to Naples familiar with the old Funicular Railway that for twenty-three years has been in operation on Mount Vesuvius will welcome the news that the long and dusty drive from Naples to the old station has at last been obviated by the opening of a new electric railway. The starting point of the new line, which has been constructed for Thomas Cook & Son, the tourist agents, is at Pugliano, where connection with Naples by electric cars is made. The length of the railway, exclusive of the old line up the cone, is 4.7 miles, and it is divided into three sections. The first and third sections are ordinary lines; the second section is a rack railway, with an incline as great as that of the famous Rigi Railway, in Switzerland. The cars of this section are pushed up by a powerful four-wheeled electric locomotive, fitted with an elaborate system of ordinary and emergency brakes. The current throughout is picked up by overhead trolleys. At the Hermitage Cook's have built a hotel, near the famous Royal Observatory. The new line makes the trip from Naples to Vesuvius a much more speedy and comfortable journey than it has hitherto been.

AUSTRIAN TRANSMISSION SCHEME.—Mr. S. C. McFarland, United States Consul at Reichenberg, Austria, says: "A project for the establishment of a central distributing electric power and light plant in the Reichenberg land district has taken definite form. The territory included is about 10 miles square, and 24 towns and villages have joined in the movement and subscribed to the capital stock. Some 10 more are expected to join. The population of the district, exclusive of Reichenberg, is about 60,000. Stock is subscribed at present to the amount of $200,000, and this it is proposed to increase to $400,000. The principal purpose of the corporation will be the distribution of electric light and power, with the possibility of installing and operating a system of suburban electric tramways. Tramway and light franchises for the city of Reichenberg are at present owned by private corporations, and at their expiration it has been generally supposed that the city would take over and conduct the enterprises. Negotiations are pending, however, which may change the situation in this respect. Communications regarding equipment, etc., may be addressed to Directors Alfred Ginskey, Maffersdorf and Dr. Richard Pirkl, Reichenberg."

LETTERS TO THE EDITORS.

Maximum Efficiencies of Transformers and Constant Potential Shunt Motors.

To the Editors of Electrical World and Engineer:

SIRS:—Dr. Kennelly's article on "The Efficiency Curves of Constant-Potential Transformers," in your issue of April 16, I have read with much interest. Dr. Kennelly has given to an old proposition a new and elegant graphical solution. He has also drawn attention to the fact, which I do not remember to have seen mentioned before, that the efficiency curve of a constant-potential transformer is an acute hyperbola.

Permit me, however, to call attention to the fact that the chief conclusion of Dr. Kennelly's paper was published in two articles of mine in the ELECTRICAL WORLD AND ENGINEER for September 18 and November 6, 1897. In these papers will be found the analytical proof that at maximum efficiency the copper and iron losses of a transformer are equal to each other. This is the main point in Dr. Kennelly's summary.

Further, for the past three years I have given to my class in electrical design a similar demonstration to show that in a constant-potential shunt motor, at maximum efficiency, the approximately fixed losses are equal to the variable copper loss in the armature. This conclusion is not so exact for the shunt motor as for the stationary transformer, but I have applied it in tests made on a number of motors and have found it to hold near enough for many practical purposes.

The demonstration is as follows: Let b be the fixed losses in watts in the motor, including iron loss, field current, windage, etc. The armature copper loss is I^2R, in which R is the resistance of the armature. Then at any load the losses are $I^2R + b$, while the input is $I E$, where E is the constant-potential difference at the terminals of the motor. Then for maximum efficiency the fraction $\frac{I^2R + b}{I E} = c$ should be a *minimum*. Differentiating, $\frac{dc}{dI} = \frac{R}{E} - \frac{b}{E I^2} = 0$ for a minimum. Whence we have

$I^2R - b = 0$, or $I^2R = b$. Hence, at a load giving maximum efficiency, the copper loss in the armature is equal to the fixed losses, or the stray power losses plus the loss in the shunt field.

UNIVERSITY OF MICHIGAN. HENRY S. CARHART.

Steam Turbine Economy.

To the Editors of Electrical World and Engineer:

SIRS:—The writer was interested in the letter in your issue of March 5 from Mr. Cyrus Robinson regarding the steam consumption of an air pump used in testing a 1,250-kw turbine unit. On several different occasions I have put a steam indicator on our air pump (which has an 8-in. steam cylinder, and two 20-in. air cylinders, with the vacuum being from 28 to 29 in.), and found the steam consumption to be 9 indicated hp. We are aided a good deal by running the exhaust steam from the air pump and some of the other auxiliary machinery into the condenser, so that the engines are run condensing. This statement may be of some interest to those who are anxiously inquiring about turbine efficiency.

PORT HURON, MICH. J. E. DAVIDSON.

Silicon and Silica.

To the Editors of Electrical World and Engineer:

SIRS:—On page 733 in your issue of April 16, in a report of the Washington meeting of the American Electrochemical Society, I am quoted as suggesting the use of silicon as a possible substitute for glass as a container for standard cells. Some erratic genius inserted the remark that pure silicon is now made cheaply by a certain patentee.

My suggestion made no reference whatever to silicon, but to silica, sometimes called "quartz glass." In view of the solubility of various forms of glass, and the great liability of glass varying in composition in different countries and at different times, it is advisable to investigate the effect of glass containing vessels for standard cells, and possibly to substitute therefor vessels of silica, which does not vary in composition and is much less soluble than any of the ordinary glasses.

New York City. Henry Noel Potter.

Reciprocating vs. Turbine Engines.

To the Editors of Electrical World and Engineer:

Sirs:—In the communication of Mr. Hodgkinson, criticising the writer's article in your issue of April 2, he first states that the data published in the article appeared to be reliable, and then proceeds to intimate that there are discrepancies in the results given as compared with those in the paper of Messrs. Moultrop and Curtiss, read before the A. S. M. E., which was referred to in the article. This paper specifically gave only the results of four single tests at full load made with and without the reheater for engine No. 8, and with and without the reheater for engine No. 9, respectively. The writer's article stated definitely that the average results given were made up from all the acceptance tests, which were made with reheaters in use, of engines No. 9, No. 10 and No. 11, and that the results of tests on engine No. 8 were not included for the reasons given. The least that can be said is that there are no grounds for the comparison made by Mr. Hodgkinson. Necessarily, from the above, only one of the tests mentioned in the paper by Messrs. Moultrop and Curtiss was used in making up the average results given in the article. The individual tests given in the latter were not mentioned in the paper, nor were the tests on engines No. 10 and No. 11, which in fact were made at a date subsequent to its reading.

It would doubtless have been somewhat more satisfactory, for purposes of comparison, if these engines had been tested at less than half load. On the other hand, it is not often possible to obtain such an accurate measure of the actual performance of an engine as is afforded by carefully conducted tests of several identical engines under substantially identical conditions. Furthermore, it is unfortunate that no reliable electrical instruments were available in the series of tests conducted by Prof. Hollis and Prof. Marks. At the same time the rates of B.T.U. per minute and the corresponding efficiency ratios given, respectively, on an indicated horse-power basis for full, quarter and half loads for these tests, and for the corresponding points on the curve *C*, form just as reliable and satisfactory a check upon the form of curve *C* for steam consumption at light loads as though direct electrical readings had been obtained.

Mr. Hodgkinson objects to the method of indicating the relation of total losses at different loads, shown in Fig. 2. In the original article by Mr. Mattice, the comparative percentage of the total losses at different loads was discussed. In laying out Fig. 2, the basis of comparison indicated by Mr. Mattice was followed. Moreover, the observations indicated include those obtained from a number of engines in other locations differing both in combined efficiency and in steam consumption, and this affords a comprehensive method of determining the law of variation of the total losses. In this connection a typographical error in the second sentence on page 652 should be noted. It should read: "The efficiency ratio given in the table, etc."

The objection of Mr. Hodgkinson that the article does not state whether allowance had been made for variation from contract conditions in determining the basis of full load rating in laying out curve *C*, is well taken. In laying out this curve it was considered proper to determine full load on the basis of rated cut-off, as indicated by Mr. Hodgkinson, which, under the actual conditions, gives a full-load rating of 2,040 electrical horse-power.

The point of Mr. Hodgkinson's comments on the necessity of expansion to back pressure for maximum economy with an ideal engine is not apparent. No one would attempt to run an actual reciprocating engine of the condensing type and expand to back pressure with the idea of securing good economy, or to maintain that there was any similarity between a reciprocating engine and the steam turbine in this respect. What the writer intended to show in this connection was that when the economy of any type of engine is improved by a reduction of the clearance due to the use of a longer stroke or better design, or by a reduction of cylinder condensation from the use of reheater or superheated steam, or in any way which improves the ratio of its thermal efficiency to that of the ideal engine, the resulting saving in steam consumption will be proportionately greater at light than at heavy loads, and the curve of water consumption for light loads will be flattened, as shown in curve *C*. This is equally true of any make of reciprocating engine which is so constructed that high economy is secured.

Mr. Hodgkinson asserts that the curves of steam consumption given show "an important feature of the turbine—that it may be run at full load with its best economy—whereas an engine must be run at about 25 per cent. underload to secure its best economy." This last clause seems like hair-splitting, since results indicated by curve *C* show a rate of steam consumption from half to full load, which is practically constant; that is, it varies less than 2 per cent. from the full-load economy. These engines also have an overload capacity of over 80 per cent. above rated load if the steam pressure and vacuum be maintained.

Mr. Hodgkinson's argument that this reciprocating engine with its practically constant rate of steam consumption from half to full load, and with its large overload capacity is over-rated, and that the general form of its curve of steam consumption for different loads is inferior as compared with the corresponding curves given for the turbine in question, appears like an attempt to befog the situation, in view of the fact that since the turbine curve falls away materially with any reduction of load below full load, on the one hand, it must be run at full load to secure economy; and on the other hand, it can carry no overload unless an attendant is on the spot to open a hand-operated by-pass arrangement for letting steam pass directly from the boiler around the high-pressure end of the turbine, with consequent increased drag upon both boiler and condenser. In fact, the by-pass arrangement hardly seems for overloads "one that is suitable for the most exacting demands of fluctuating loads."

According to his figures, if the vacuum should fall to, say, 21 in. instead of 25 in., which, however, does not seem unreasonable, the capacity of the turbine would be cut down 30 per cent., with a corresponding increase in steam consumption, and under such conditions with a drop in steam pressure of 10 per cent., the turbine would not pull its rated load, with by-pass full open.

Mr. Hodgkinson asks in several places in his letter for more tests —more data. This is an invitation to a controversy which the writer must decline, and it does not seem that this would interest your readers. The article was intended solely to correct a prevailing wrong impression that a reciprocating engine, even when of the highest economy at full load, must necessarily be wasteful of steam at light loads, an impression which turbine advocates have made use of a great deal in making comparisons. It was in no sense meant to cover the general subject of the comparative economy of turbine and reciprocating engines, in which case an allowance for the material difference in vacuum, etc., would have been proper. For such a comparison the present time seems inopportune to the writer. The results of tests by disinterested parties of steam turbines which have been in actual service for a sufficient number of years to judge properly of their lasting qualities are too poor to be worth comparing with an up-to-date reciprocating engine. Only a trying-out process will determine, not only how far the expectations of greatly increased economy will be realized from the many improvements in steam turbines which are being actively exploited at the present time, but, *more especially*, how these improvements will affect the durability and lasting qualities of the turbine. There would seem to be no difficulty in making a turbine which will give, after careful adjustment, good results for a short time, provided sufficiently close clearance or sufficiently high steam velocities are used. The question is how far can one go in this direction in a machine which will at the same time prove sufficiently robust for commercial handling, and will also prove to be durable and without deterioration in economy. It would seem that time is needed to solve this problem.

Auburn, N. Y. J. A. Seymour.

Variable-Speed Motors.

To the Editors of Electrical World and Engineer:

Sirs:—The writer has been using electric-driven machine tools for some time. He has used variable-speed motors, obtaining his speed changes by varying the field strength. He has, however, had some trouble with the motor starters and field rheostats. So much has been written lately regarding systems of control for variable-speed motors that the writer thinks some attention should be paid to special types of controllers for use with variable-speed motors. From an operator's standpoint, I have the following complaints to make against apparatus which I have received from motor manufacturers who have sold me variable-speed motors with their controlling outfits for my machine tools:

1. Upon weakening the field to get higher speed, the underload release magnet has released the arm and stopped the motor.

2. Upon starting up under load my fuses have blown, the underload magnet not being operative during the starting period.

3. Upon starting the motor under weakened field conditions while under the lightest load, my fuses have blown.

4. I have had some trouble due to metallic chips falling upon the exposed resistance coils in the box, causing short-circuits, thus destroying the box.

I believe, therefore, that some better apparatus could be constructed and that some attention should be given this question as it is the only complaint which the writer has found against the driving of milling machines and such class of goods by use of variable-speed motors. I would thank any of your readers who wauld take this matter up and co-operate with me.

Bronxville, N. Y. Chester Burkhardt.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Converters.—Loewy.—In a continuation of his serial on electric machine construction in 1903 he discusses converter designs by Davis, Lamme, General Electric Company, Auvert and the following machine of Bragstad and La Cour. The latter, shown in Fig. 1, consists of an induction motor coupled with a rotary converter, *U*, the secondary winding, *R*, of the induction motor being connected to the armature winding of the converter. *S* is the stator winding of the motor, *W* the starting resistance, *K* the commutator, and *F* the direct-current field of the converter, which is in shunt with the direct-current circuit. If motor and converter have the same number of poles, the two machines coupled together run with a speed which corresponds to half the frequency of the primary current. An e.m.f. of half the frequency of the primary current is thereby induced in the rotor winding of the induction motor. On account of the connection of the rotor winding with the armature winding of the converter, a rotary field is produced in the latter which revolves (with regard to the armature) with a speed equal to that of the armature. If the connections are so made that the rotary field revolves in the opposite direction as the armature, then the rotary field is stationary in space and the machine acts at this speed like a synchronous motor. The induction motor acts to one half as motor and to the other half as transformer, while the converter acts to one half as direct-current generator and to the other half as converter. The relative position of both stationary converter fields depends upon the load of the machine, and the relative position of both fields can be changed only by an external force. In the case of an external disturbance there exists a strong synchronizing force, because there is only a relative displacement of the converter fields, but also one of the fields of the induction motor. For starting the converter, the resistance, *W*, is used which is gradually disconnected so that the speed gradually increases. With correct excitation, the condition of synchronism is reached by itself and the resistance may be short-circuited. The arrangement is shown of using the machine for converting single-phase into direct current and also for using it as an alternating-

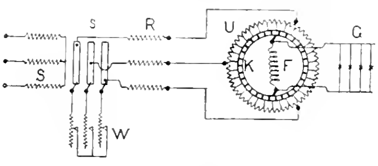

Fig. 1.—Converters.

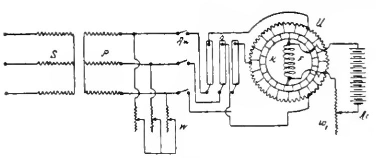

Fig. 2.—Converters.

current motor. Fig. 2 shows the application of such a motor for three-phase traction. The stator winding, *S*, is placed between the rails on the road, while the rotor winding, *P*, is mounted on the car. The converter, *U*, is connected to the driving axle of the car. When starting, the switch, *Au*, is open, and the car is started partially by means of direct current from the battery, *Ac*, and by means of three-phase current. When the speed is reached at which the frequency of the three-phase current induced in the rotor is equal with that of the armature current of the converter, the switch, *Au*, is closed and the resistance, *W*, is opened so that the car continues to run at this speed, which corresponds to synchronism. When the resistance, *W*, is decreased the speed of the car increases and the converter, *W*, sends current into the battery, *Ac*. Fig. 3 shows the application of the machine as alternating-current generator with the non-synchronous machine, *G*, as main generator and the converter, *Er*, as exciter. The exciter and the generator are self-exciting if the field of the exciter has body poles. The alternating currents generated in the exciter produce a rotary field in the rotor of the non-synchronous machine. The currents induced in the stator of the non-synchronous machine have a frequency which is equal to the sum or difference of the speed of the rotor and the speed of the rotary field in it. Such a generator is, therefore, suitable when connected with high-speed prime-movers, like steam turbines, for furnishing alternating current of a lower frequency than would correspond to the speed of the prime-mover.—*Zeit. f. Elek.* (Vienna), April 10.

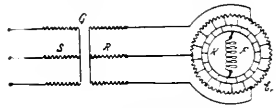

Fig. 3.—Converters.

Alternators Connected in Parallel.—Sommerfield.—The first part of a long theoretical article. The author first sums up the former papers by Kapp, Benischke, Goerges and Rosenberg on this subject. The common feature of the various explanations given by these authors is the consideration that by the driving machine a forced oscillation is impressed on the machine set and that on the other hand, the system is capable of a free oscillation, the period of which depends upon the mechanical and electrical constants of the two machines. The special phenomena of surging make themselves manifest when both oscillations are in resonance. Benischke also emphasizes the possibility of interference between the free and forced oscillations. The influence of the regulator may be considered as a separate problem. The present author starts from the mechanical and electrical differential equations of the generation of current as the simplest foundations of the phenomena. He does not discuss the process of connecting in parallel, but speaks only of the conditions which are obtained when the connection in parallel is made in the proper way at equal instantaneous values of voltage and when the main power of both machines is equal. His mathematical equations lead him to a mechanical analogy with the pendulum and he has devised an apparatus which he calls the "sympathetic pendulum" for demonstrating the phenomena of surging. The article is to be concluded.—*Elek. Zeit.*, April 7.

Distorted Magnetic Fields.—Goldschmidt.—The first part of an article, illustrated by diagrams, on distorted alternating and rotating magnetic fields. It is pointed out that an induction motor shows great sensitiveness to distortion of the voltage curve, especially to the higher harmonics of the lower orders, such as the third, fifth and seventh harmonics. The following experiment is described. A no-load test on a 400-volt, 50-period, 1,000-revolution, 70-hp, three-phase motor was first carried out, using a small generator which had been designed for about 350 volts and 50 amp. This was over-excited to give 400 volts and the test showed a no-load current of 42 amp. The test was then repeated using a three-to-one ratio transformer to raise the voltage so that the generator should be working with a much higher current at a lower voltage, the percentage voltage drop being increased approximately nine volts. The transformer also had a considerable drop at the load employed. With the same voltage (400 volts) at the motor terminals, the no-load current now measured only 30 amp., against 42 amp. when supplied directly from the generator. The chief cause of the difference was curve distortion. In the first test this distortion had full play, while in the second the high reactance of the circuit prevented the occurrence of currents of high frequency.—Lond. *Elec. Rev.*, April 8.

Lights and Lighting.

Train Lighting.—An account of the results obtained with various systems of electric train lighting on the State Railways of Prussia. On the D-trains, between Berlin and Stassnitz, and between Berlin and Altona, the following system has been in use for over a year and has proven very satisfactory. The lamps in all cars are supplied with current from one steam dynamo consisting of a 20-hp Laval turbine geared to a shunt dynamo and placed on the locomotive. The cars are provided with batteries which supply the lighting current only when the locomotive is disconnected from the train. In case of an accident to the machine, the batteries are capable of furnishing current for all lamps for three hours. Since the machine and the battery are continually at the lighting circuit, while the voltage must be changed from 64 to 86 for charging the battery, the lamps are in series with iron wire resistances. As has already been noticed in the Digest, these consist of fine iron wires in glass tubes, filled with hydrogen. If the current increases, the resistance increases in such a way that the voltage at the lamps remains approximately 48, while the voltage of the network is increased from 64 to 86. The same system is used on the new passenger cars for D-trains between Berlin and Cologne and between Berlin and Basel, only the generating plant is constructed in a different way. It consists of a dynamo driven by a car axle. The 17-kw generator has two shunt windings and one main winding. One of the shunt windings is connected to the battery, the other to the machine terminals. In both shunt windings the current is kept approximately constant by means of iron wire resistances, so that the machine voltage remains between 64 and 86 volts for speeds beginning with 40 km. Aluminum cells are inserted between battery and machine to prevent current from flowing back from the battery to the machine when the voltage of the machine decreases. The well-known property of aluminum electrodes to allow the current to pass in one direction only, is here made use of. The system has been used for three months and has been found satisfactory. On other trains experiments have been made with lighting each car separately, a dynamo driven by the axle and one or two auxiliary batteries being provided. The total cost of first installation for the latter system has been $3.63 per candle, for the system used between Berlin and Stassnitz $5.12, for the system used between Berlin and Altona $4.62, for the system between Berlin and Cologne $3.50, and for the system between Berlin and Basel $3.75. The cost for installing gas lights in some new D-train cars amount to about $1.81 per candle. The cost of operation which can only be given after a long time of use will be smaller for electric light than for gas light and will be smaller for lighting a whole train from one source than for lighting each car separately. If interest, amortization and cost of operation are taken into account, it will be seen that the cost of electric lighting a train is considerably higher than gas lighting, if the lamps are lighted only for a few hours. The longer the time the lamps are lighted each day, the smaller will be the cost of electric lighting, and it may even become smaller than that of gas lighting. A table is given on the power consumption in the Stone system for car lighting.—*Zeit. f. Elek.* (Vienna), April 10.

Power.

Electricity in Mines.—Schulte.—An illustrated description of the electric power transmission plant of the Courl mine near Dortmund, in Germany. In 1897 a small underground primary station was erected in the mine, consisting of a 90-hp steam engine coupled to a 2,000-volt, three-phase generator, which supplied several induction motors. On account of the large extension of the mine the high voltage of 2,000 was chosen. This installation was found to be very satisfactory, so that in 1900 it was decided to erect a larger primary station above ground, consisting of a 630-hp steam engine coupled to a 2,000-volt, 550-kv-amp., three-phase generator, the frequency being 50. Afterwards a second steam dynamo of 550 kv-amp. was installed and both dynamos are operated in parallel. In the mine there is water falling from one level to another, 240 meters deeper, and this has been utilized for driving a Pelton wheel coupled to a 100-kv-amp., three-phase generator. There are installed in the whole 16 motors with an aggregate capacity of 510 hp over ground and 30 motors with an aggregate capacity of 747 hp in the mine. For the underground motors the voltage is transformed from 2,000 to 215 by transformers, placed near the motors. The motors are used for driving ventilators, for hauling and various power purposes. By this means a centralization of the total power generation has been accomplished which has produced a saving of $21,000 in the year 1903, against the year 1901, which can be traced accurately, while the actual saving is larger.—*Glückauf*, April 9.

Water Power Stations.—Adams.—An illustrated article giving various examples from American practice. Cost of water power development depends in a large measure on the location of the electric station which is to be operated. In Burlington, Vt., the upstream wall of the station serves at the same time as a dam, there being neither canal nor long penstocks and only one wall of the power house apart from the dam. The peculiar natural conditions favorable to such a construction are seldom found. In many cases in comparatively level country a water power can be only fully developed by means of canals or pipe lines, and the generating stations cannot be located at the points where the water is diverted. In mountain districts it is generally necessary to employ rather long canals, flumes or pipe lines and an important question is whether to erect one or several stations. Whether the expense of extending conduits and pipe lines to a single generating station will more than offset the advantages to be gained thereby depends on a number of factors, but in general the smaller the volume of water to be handled and the greater its head, the more advantageous is it to concentrate the generating machinery in the smallest practicable number of stations.—*Cassier's Mag.*, April.

References.

Electric Power in Ship Yards.—Brown.—The conclusion of his fully-illustrated article on the application of electric power in British ship yards with special reference to the North East coast. A great many different applications are shown and described, and it is pointed out that in a comparatively short time the introduction of electric power has brought about in that district not only a complete change in the manufacturing methods of the shipbuilder, but in the characteristics of his business. "It may safely be predicted that at the end of the next decade there will not be a steam engine at work in the district driving a ship yard machine tool, and that electric power will be exclusively employed."—*Cassier's Mag.*, April.

Electricity in Mines.—Guarini.—Two illustrated articles on electric installations in mines. The first deals with electric signalling and electric ventilators, the second with electric ore cutters, electric locomotives and hauling machines. Finally, several electric installations in mines are described.—*L'Eclairage Elec.*, April 2 and 9.

Traction.

Field Coils.—An illustrated account of some changes which were made with General Electric 57 field coils by the St. Louis Transit Company. They are made of flat bare copper strips wound with a strip of asbestos between the turns. Two such coils make up one field coil. They are wound side by side on a brass shell. The brass shell carrying the coil is slipped over the pole piece. It was found that frequently one or two turns would be short-circuited by contact at the edges of the copper strap and that the vibration of the coils in the brass shell often ruined the insulation. The new plan is to wind up the two sections of the field coil separately on a wooden form using the copper strap and asbestos as before; it is then taped and the coil is dipped in insulating paint and covered with a special cloth and another layer of tape. The two coils are then laid side by side, connected together and covered with canvas, micanite and red board. The whole is then dipped again in insulating paint. Instead of using the brass shell for mounting on the field poles, two pressed-steel forms are used. As the pole piece is drawn in place the insulating covering of the coils is pressed so as to hold the field coil firmly and prevent vibration.—*St. R'y Jour.*, April 16.

Liverpool-Southport Electric Railway.—Rinkel.—A brief communication in which the author thinks that the use of a fourth rail (between the two running rails) for the return current is not suitable, since the maintenance of the track is not as good as when the running rails themselves are used for the return current, and, therefore, provided with rail joints. The author refers to the fact that in such extended railways in the United States and England a tension of 600 volts is still used, while the experience of the Wannsee road and on the Berlin elevated road have shown that an average voltage of 800 is thoroughly feasible. He asks whether the construction of motors in Germany is further developed in this respect than in England or the United States.—*Elek. Zeit.*, April 7.

REFERENCES.

Electric Railways of New Jersey.—A description and map are given of the electric railways in the State of New Jersey, particularly with reference to the lines between New York and Philadelphia. While it is now possible to travel from one city to the other by electric railway exclusively, through car trips are not yet possible owing to differences in track gauge. Most of the lines are of interurban character, but do not use such heavy equipment and attain such high speeds as is common on the interurban lines in Ohio and Indiana. The only large system is that of the Public Service Corporation, which owns the lines connecting the most important cities of northern New Jersey.—*St. R'y Jour.*, April 16.

Electric Traction in Italy.—Koromzay.—An article giving some critical notes on a former paper on this subject by Vaudeville. The present author appears to be somewhat more in favor of three-phase traction, compared with direct-current traction, than the former author was.—*L'Eclairage Elec.*, April 19.

Berlin and Paris.—Jacquin.—The first part of an illustrated article on the various traction systems of Berlin and Paris.—*La Revue Elec.*, March 30.

Single-Phase Traction.—An editorial note on some American papers on this subject. Concerning Steinmetz's recent Institute paper it is said that "Reading between the lines, it would seem that Steinmetz believes the repulsion motor to be superior to the series motor for traction purposes, and in this he echoes the opinion of many electrical engineers on this side of the Atlantic."—Lond. *Elec.*, April 8.

Single-Phase Traction.—Renshaw.—An article, illustrated with many diagrams, giving a summary of the various features of the Westinghouse single-phase railway system.—*Elec. Club Jour.*, April.

Installations, Systems and Appliances

Paris Central Station.—Dupuy.—An illustrated description of the plant of the Est-Lumière Company, which supplies a great many towns east of Paris with electric current. The station is located at Alfortville and contains six 700-hp steam engines coupled to alternators. The capacity of each alternator is 540 kw, the voltage 5,240, the power factor 0.75, the frequency 50. The current is transmitted to the various sub-stations by six underground feeders. The transmission voltage is 5,000. In the sub-stations transformers reduce the voltage to either 250 or 110, which is the tension of the distributing system. Data are given which show that this station has been a financial success.—*L'Eclairage Elec.*, April 9.

Protection of High-Tension Lines Against Atmospheric Discharges.—Benischke.—A report of a committee of the Berlin Electrical Society, giving a summary of answers received from various stations on an inquiry with regard to accidents due to atmospheric discharges during 1903. In 41 cases accidents had occurred and since in these cases all known systems of lightning arresters were used, it seems that an absolutely sure safety device does not yet exist. In a certain plant in Bohemia where accidents due to atmospheric discharges appear to occur very often, four different systems of lightning arresters were used simultaneously; nevertheless, three transformers were disabled last year. Experience seems to show that it is useful to insulate the iron frames of the machines and apparatus from earth. In various cases atmospheric discharges were observed while there was no thunderstorm and in other cases lightning arresters, insulators and line poles were destroyed by direct lightning flashes.—*Elek. Zeit.*, April 7.

Circuit-Breaker.—Bruell.—An article, illustrated by diagrams, on a circuit-breaker for protecting electric lines against currents, dangerous by their duration and intensity, while the circuit is not broken for harmless short increases of the current. The principle is that the flux of the electromagnet which operates the circuit-breaker does not only depend upon the intensity of the current in the line, but upon the thermic conditions of the circuit. For this purpose a resistance is added to the coil of the circuit-breaker and this resistance is a function of the thermic conditions of the line to be protected. The variation of this resistance produces in the coil a variation of current which also is a function of the conditions of the circuit. The variable resistance consists of a metal with a high temperature coefficient, like iron or nickel, subjected to the heat effected by the current and placed under convenient conditions of temperature, caloric capacity and radiation. Several applications of this principle are described and exact data are given for an apparatus based on this principle.—*L'Eclairage Elec.*, April 2.

Insulation Material for Wires.—An article on the insulating material, devised by Hackethal, which has been repeatedly noticed in the Digest. It is formed of a vegetable tissue impregnated with linseed oil and minium and used to good advantage in Germany for telephone wires, especially in the neighborhood of tramway lines. It has also given good results in chemical plants on account of its resistivity against the corrosive action of an atmosphere saturated with acids. Boehm-Raffay recommends the same insulating material for transmission lines and remarks that when too high a current flows through the wire the insulation may be dried out and may even carbonize, but will not burn. Wires of 6 mm. diameter were supplied for several hours with a current density of 50 to 60 amp. per sq. mm., but did not show the slightest dangerous phenomena.—*L'Elec.*, April 2.

REFERENCE.

Telephone Cables.—Schmidt.—An illustrated description of the methods used by various manufacturers for making telephone cables with a plurality of wires with air insulation.—*Zeit. f. Elek.* (Vienna), April 10.

Electro-Physics and Magnetism.

Emanation from Radium.—McClelland.—A paper in which the author remarks that the emanation produced by radium has been much studied and many of its properties are known, but it had so far not yet been definitely settled whether or not the emanation particles are charged. The author has tested this point and has found that the emanation is not charged. This result has a bearing on our conception of the manner in which the radium atom breaks up. The radium atom certainly gives off positively charged particles—the α rays. The emanation particles cannot be what remains of the atom after the emission of one or more α rays, because in that case it would be negatively charged. The atom must have parted with an equal negative charge either by the emission of negative particles or in some other way.—*Phil. Mag.*, April.

Radioactivity.—Becquerel.—The first part of an article on the radioactivity of matter. In the present installment he discusses the discovery of the radioactivity of uranium, and the radiation from uranium.—*L'Eclairage Elec.*, April 2.

Alternating-Current Diagrams.—Karapetoff.—The first part of an illustrated serial on applications of alternating-current diagrams. The present installment gives elementary examples.—*Elec. Club Journal*, April.

Alternating-Current Working.—Gump.—The first part of what will probably become a long serial illustrated by diagrams in which the author intends to treat in a simple manner with the fundamental principles of alternating-current engineering.—*West. Elec.*, April 9.

Radiation from a Circular Circuit.—Orr.—A mathematical note on the radiation from a perfect conductor in the form of a very thin circular ring, which carries an alternating current.—*Phil. Mag.*, April.

Electro-Chemistry and Batteries.

Calcium Carbide.—Moissan.—A French Academy note on a new experimental process for making calcium carbide. Metallic calcium combines with lamp black at any temperature above red heat. In any electrolytic process, therefore, where calcium is produced in contact with carbon at red heat, calcium carbide is formed. The author bases a new carbide process on this consideration, which, however, appears to have no commercial value, since the carbide obtained is firmly embedded in a fused mass of calcium chloride and fluoride. A carbide crucible which serves as the positive pole is filled with calcium chloride fused by means of a small electric arc. A vertical rod of graphite serves as a negative electrode. The chloride is put in gradually and after the first fusion electrolysis is carried out by means of a current of 10 to 15 amp. at 120 volts. Chlorine is given off freely and after an hour the process is stopped and the crucible broken. Under the crust is found a mass with a crystalline fracture. The central portion dissolves in water and evolves a mixture of gases containing some 14 per cent. of acetylene, the rest being hydrogen. The process is greatly improved by mixing the chloride with a quarter of its weight of fluoride, which makes the mixed mass more fluid and the conduction of the current more regular. The amount of graphite obtained is small, but it may be increased by adding to the liquid a coarsely-powdered mass of petroleum coke.—*Comptes Rendus*, March 14; Lond. *Elec.*, April 8.

REFERENCE.

Ferro-Silicon.—Amberg.—Ascherman has claimed that by treating a mixture of iron sulphides with quartz in an electric furnace under proper conditions, a reaction may be obtained, yielding ferro-silicon and sulphur dioxide. This would represent an important progress, since the use of carbon as reducing agent would be eliminated. The present author has made an experimental study of this problem, but has found that there is very little hope for the conduction of a process like that of Ascherman on a commercial scale.—*Stahl und Eisen.*, April 1.

Units, Measurements and Instruments.

Comparison of Capacities.—McClelland.—An application of radioactive substances for a simple and accurate method for comparing capabilities. The method is suitable for the determination of capacities of any magnitude down to a few micro-microfarads or even less. The method is based on the fact that the ionization current that can be obtained by the use of a radioactive substance like uranium is extremely constant and can be made so small that the time taken to charge a condenser by it can be accurately measured. This small constant current is used first to charge one condenser to a given potential; and then a second condenser is charged to the same potential, and the time taken in the two cases observed, so that we get the ratio of two capacities by simply observing two intervals of time. It is not necessary to have a supply of radium; uranium is even better in some respects and uranium is to be found in every laboratory. In Fig. 4 *A* and *B* are two insulated plates, one of which, *B*,

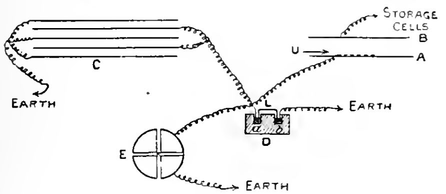

FIG. 4.—COMPARISON OF CAPACITIES.

can be joined to one terminal of a battery of small storage cells, the other terminal of which is to earth. The battery may consist of 100 or more small test-tube cells, so that *B* can be kept at 200 volts or higher. A few grams of uranium nitrate are spread on a sheet of paper and placed on the plate *A*. The radiation from the uranium ionizes the air between *A* and *B*; and so *A* gradually rises in potential if insulated, supposing *B* to be positive. The ionization current thus obtained between two plates increases at first as the potential differences between the plates increases. But when this potential difference is made sufficiently great, the current attains a maximum and does not further increase, for further increase of potential difference between the plates. If, then, *B* is kept at a sufficiently high potential, small changes in this potential, due to the potential of the battery falling, will produce no effect: and again, in making an observation, the potential of *A* need never change by more than one volt, so that there is no trouble in keeping a constant current to the plate *A*. *C* is one of the condensers being compared and *E* is a quadrant-electrometer. *D* is an insulating block of paraffin, containing two mercury cups, *a* and *b*, one of which is connected to earth. A connecting piece, *L*, joins the mercury cups and can be lifted out and lowered again from a distance. As soon as *L* is lifted out, *A* and *C* and *E* begin to charge up; and the time is observed during which the spot of light moves, say, over 100 scale divisions. An exactly similar experiment is made with a second condenser, C^1, instead of *C*. If the intervals of time are t and t^1, respectively, then $C + c$ to $C^1 + c = t$ to t^1, where c is the capacity of the electrometer, the condenser, *A B*, and the connecting wires, and can be determined in terms of *C* by taking an observation with *C* joined of as shown in Fig. 5, and then an observation with *C* disconnected so that only *c* is charged.—*Phys. Mag.*, April.

Optical Ammeter.—Orlich.—A description of a method for measuring currents which is employed at the Reichsanstalt for testing alternating-current ammeters. It consists in heating to incandescence a sheet of platinum foil by a continuous current and an alternating current in succession. If the effective value of the alternating current equals that of the continuous current, the amount of heat developed in the platinum foil is the same in both cases, and if the emission is also the same, the sheet must attain the same temperature in both cases. The equality of temperature may very conveniently be tested by Holborn and Kurlbaum's optical pyrometer. An image of the glowing platinum is projected by means of a lens upon the filament of a small incandescent lamp, which is observed through a second lens. The current feeding the lamp is so regulated that the filament apparently disappears in the bright background. Special provision has to be made for constancy of temperature. As regards radiation, it is kept constant by allowing the platinum to radiate into the open air, and the conduction of heat is kept constant by perforating the electrodes and supplying them with a stream of cold water. The temperature imparted to the platinum sheets varied from 400 to 1,400°. At higher temperatures the method loses in sensitiveness, and the platinum begins to evaporate. The author quotes a number of tests of commercial ammeters. A Kelvin hectoampere balance with subdivided copper leads gave correct readings, but a kiloampere balance containing massive leads required an alternating-current 5 per cent. stronger than the corresponding direct current to produce the same temperature.—*Zeit. f. Instrumentenk.*, March; Lond. *Elec.*, April 8.

Testing Induction Motor Windings.—Garcelon.—An illustrated article in which the author describes tests of induction motor windings. The test is based upon the fact that any error in the winding will destroy symmetry of the magnetic field produced by the winding when single-phase alternating current is passed through it. This, in turn, will affect the impedance of the winding. The first test to be made is always to determine whether or not the winding is correct. This is done by observing the impedance drop across each phase. If these readings indicate an error, then a second test—or location of the error—must be made. The point where the fault exists is indicated by an irregularity of the field-form, which may be investigated by moving an exploring coil around the core. A simpler way is to measure the drop from stub to stub, the stubs being easily exposed by removing the tape. These drops should be alike for each coil symmetrically located with respect to the poles. The author shows how such mistakes as a reversed phase or a reversed group affect the first part of the test and locate themselves at once without an application of a second or locating test. A suitable switchboard for making such tests is described and illustrated.—*Elec. Club Jour.*, April.

Hot-Wire Voltmeter.—Threlfall.—An illustrated description of a new form of sensitive hot-wire voltmeter. The chief peculiarity of the instrument is in regard to the means adopted for securing uniformity of tension of the fine silver wire. The active wire is carried between two adjustable supports, one of which is insulated from the rest of the apparatus. The other support can be moved to and fro in the direction of the wire by means of a micrometer screw. The wire is pulled down at the center by a microscopic hook and spiral spring insulated from the base. A small mirror hinged on a wire stretched alongside rests on the head of the hook. As the active wire heats up, the hook descends and the mirror is tilted downward. There is a small incandescent lamp in the lid of the box enclosing the instrument, and a scale opposite a slot in the front of the case. By means of a prism and lens an image of the filament is thrown on the screen by the mirror, and by turning the micrometer screw this image can be brought to any desired point. Small voltages can be read off at once on the scale, but larger ones are compensated by working the screw.—*Phil. Mag.*, April.

New Books.

DIZIONARIO TECNICO IN QUATTRO LINGUE. II. Tedesco, Italiano, Francese, Inglese. 2 Edizione. Ing. Edoardo Webber. Milan: Ulrico Hoepli. 611 pages. Price, 6 lire.

This is a handy little volume of technical expressions in four languages—English, French, Italian and German—for it is more than simply a dictionary. It is arranged alphabetically, each two pages being printed in four parallel columns, thus: Deutsch, Italienisch, Französich, English. The volume for each language has the phrases alphabetically arranged in the first left-hand column, while the corresponding translations in the other three languages are opposite in the corresponding headed columns; for example, the German volume has the German phrases arranged alphabetically on the left hand of the page, and thus to complete the set one must procure all four volumes.

The arrangement is exemplified by the following quotation:

"Ammoniakgasmotor: Motore ad ammoniaca: Moteur à gaz ammoniac: Ammoniacal Gas Motor."

The book is of convenient size, substantially bound and of excellent typography. It will be found an exceedingly handy volume for those who employ scientific technical phrases.

TRANSACTIONS OF THE AMERICAN ELECTROCHEMICAL SOCIETY. Vol. IV. Philadelphia: American Electrochemical Society. 192 pages.

Of all the applications of electricity, that of electrochemistry is the youngest and yet has perhaps made the most marvelous development. This is evidenced by the fact that the bulk of the output of the Niagara power plant is employed in electrochemical operations. Had it not been for electrochemistry aluminum would still be a precious metal, nor would carborundum or acetylene have become commercial possibilities. While electricity is the agent which makes these new commercial fields possibilities, it is only by means of the patient investigation of both electricians and chemists that the ability to so employ it has become feasible. No wonder, therefore, that the Electrochemical Society is now one of the most important scientific bodies, or that their proceedings should arouse the liveliest interest.

The present volume reports the transactions of the meeting which took place at Niagara Falls during the latter part of September, 1903. In many respects the papers presented are a marked contrast to those of other professional societies, for they are so brief as in many cases to hypothecate for comprehension an amount of special knowledge much beyond that of the average reader. The volume contains sixteen papers, among which the following appear to be of special interest: "Note on Some Theoretical Considerations in the Construction of Resistance Furnaces," by H. A. Fitzgerald. This paper briefly describes some of the conditions governing resistance furnaces and presents data valuable in designing and proportioning. "Electrolytic Copper Refining," by W. D. Bancroft, contains a quantity of data bearing directly upon the cost of the refinement of copper by electrolysis. A "Note on Berthelot's Law Relative to the Electromotive Forces of Cells," by C. J. Reed, together with Mr. Roberts' contribution on the "Electrical Properties of Free Ions in Solution," is notable as bearing upon the theory of the electrolytic cell.

To even mention all of the contents of the volume would transcend our space limit, but the reader who is interested in and desires to be fully posted in electrochemical affairs should by no means fail to secure this set of papers.

A TREATISE ON FRICTION AND LOST WORK IN MACHINERY AND MILLWORK. By Robert H. Thurston. New York: John Wiley & Sons. 430 pages, 77 illustrations. Price, $3.00.

No engineer can take up this volume without mingled feelings of affection and sorrow. Of affection because Dr. Thurston of all scientific writers most endeared himself both to the student and professional man, and of sorrow because the hand which has produced so many works has now forever laid the pen aside. The "Treatise upon Friction and Lost Work" is so well known to the entire engineering profession that to describe even this latest edition is almost superfluous. The first edition, which appeared nearly 20 years ago, was the earliest attempt to give a systematic and scientific explanation of the doctrine of lubrication, and to so guide the man in the engine room that he might select and apply lubricants with such discrimination as to produce the most successful results. From time to time succeeding editions have built upon the foundation laid by the first one, rearing a structure which has endeavored to keep pace with the art of lubrication, to embody the changes in practice which have occurred and to recommend both methods of applying lubrication and new lubricants. It is perhaps hardly exaggeration to say that Dr. Thurston's treatise laid the foundation of the modern method of lubrication now almost universally adopted in large plants, viz.: that of providing a complete system of flowing lubricant which is pumped through the bearings of every machine, returned to a filtering apparatus and again circulated after being clarified.

The present volume elaborates somewhat upon previous editions by containing a complete résumé of the improvements and changes in the practice of lubrication which have occurred during the last five years. The chapters on the method of applying lubricants, the testing and inspection of them, and the machines which have been developed for this purpose have particularly undergone modification and modernization, and as a result thereof the data relating to the action of lubricated surfaces have been correspondingly expanded and increased both in quantity and in quality.

The chapter upon the "Finance of Lubrication" will be found by the power station and mill owner to be of the greatest value and is unique in the literature of lubricants. Finally, a chapter upon "Recent Investigations and Conclusions" embodies some novel methods of plotting the results of experiments and brings the volume thoroughly into touch with modern practice.

TECHNICAL MECHANICS. By Edward R. Maurer. New York: John Wiley & Sons. 382 pages, 250 illustrations. Price, $4.00.

This volume is the latest addition to a somewhat extensive library of college text-books, of which Weisbach and Rankine were the illustrious and revered progenitors. In his preface Prof. Maurer has defined his object in stating that the work is not a treatise upon pure or applied mechanics, but a "Theoretical Mechanics" for students of engineering. A perusal of this volume fully sustains this assertion, for in many cases the mixture of pure theory with attempted applications to practice appears abrupt and harsh. Some of the definitions strike one peculiarly, for example: "An action of one body upon another which changes or which exerted alone would change the state of the motion of the other body is called a force." One ordinarily would hardly include the operations of heat and electricity, which are customarily spoken of as forces, within such a definition, but the author proceeds to explain that inasmuch as it is necessary to postulate an intervening medium for the operation of a force, this medium may be termed a body.

Throughout the entire work there is a distinctly German flavor and one constantly encounters German methods of analysis and German ways of reasoning, which, while unquestionably of value, are likely to jar a little upon the American reader. In his analysis of the subject of mechanics the author classifies as follows:

$$\text{1. Mechanics: }\begin{cases}\text{Kinematics.}\\ \text{Dynamics}\begin{cases}\text{Kinetics}\\ \text{Statics}\end{cases}\end{cases}$$

and further proceeds to state that statics is that portion which deals with uniform motion. To the bridge builder such a definition will appear somewhat forced, because while theoretically we are all aware that the ultimate particles of even the mosit rigid solids are probably in motion, yet the constructor usually regards his tension and compression members as something as solid and immovable as he can make them, and certainly hopes that they will never escape from their preassigned positions and go gyrating off into space while a limited express train is traveling across the track which they sustain.

There are three sections—Statics, Kinematics and Kinetics—and these are further subdivided into 15 chapters, which, under the heading of Statics treat of Force, Equivalence of Force System, Center of Gravity and Centroid, Attraction and Stress, General Principles of Equilibrium, and the Application of the Principles of Equilibrium.

Under kinematics, the rectilinear motion of a particle is first considered, then curvilinear motion and motion of a rigid body.

Kinetics is sub-divided into motion of a particle and of a system of particles, translation of a rigid body, rotation, work and energy, and finally impulse and momentum.

A quartette of appendices, of which the first is a brief explanation of the principles of vectors followed by a dissertation on rates of motion, the dimensions of units and moment of inertia, complete the book.

The volume is clearly and tersely written. For each problem, as far as possible, both a graphical and analytic analysis is given. The illustrations are well selected and present the various subjects clearly. From a theoretical standpoint it is attractive, but when one lays it down the academic flavor is so strong that one is inclined to wonder whether a student thereof will not be so afflicted with theoretical hydrocephalus as to be unfitted for the every-day experience of the shop or of the railway.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Twenty-sixth Convention. Published by order of Executive Committee. New York: James Kempster Printing Company. 221 pages, illustrated.

It is the fashion for those who are interested in commercial developments which lie along technical lines, to hold occasional conventions at which those interested in the particular branch represented can meet and interchange ideas. One of the earliest organizations of this kind is the National Electric Light Association, and indeed this body has almost set the pace for other similar associations to follow.

The volume in hand is the report of the *Proceedings* at the last convention, an examination of which shows a series of papers partly scientific and partly commercial, but all apropos to the best development of the particular industry. The matter presented is so carefully considered, so well arranged, so thoroughly pertinent to the questions of the day, so generally helpful, and, withal, so dignified in tone as to make one wonder at the contrast presented between the National Electric Light Association and some of the younger associations. Naturally, the present volume commences with the president's address, which is chiefly a perusal of the work accomplished by the organization during the past year.

This is followed by Mr. T. C. Martin's report upon the "Electrical Progress of the Year," a document that is replete with statistics and will put the reader perfectly *au courant* with electrical development in 1903. The next paper is a report upon office methods and accounting by Mr. W. M. Anthony, which is strictly a commercial contribution. Some one has tritely remarked that "any business can be made to pay if you know what it costs, while no business can be made to pay if you don't." This is the keynote of Mr. Anthony's report. He deals with the methods of accounting, particularly with the employment of various mechanical aids, such as the addressograph, comptometer and a number of other mechanical devices, which are aids to the bookkeeper and statistician. The author shows a number of forms applicable to electric light and street railway stations which may be studied with much profit, and, indeed, though the report is addressed particularly to the electrical fraternity it is well worth the study of any business man.

The paper on "Boiler Efficiencies," by A. Bement, and the one on the "Application of the Four-Ampere Series Alternating Arc Lamps" are particularly worthy of study to those who are interested in these subjects. "The Young Engineer in the Electric Light Plant," by Charles F. Scott; "Tactful Relations with Customers," by John W. Ferguson; "Relations with Employees," by Arthur Williams, and "First Aids and Appliances," by Dr. J. D. McGowan are not technical papers in any sense of the word, but are addressed to the business side of electric lighting and thus give to the proceedings of this Association a breadth which the transactions of purely technical societies usually lack. The paper by Dr. McGowan would have had much more value if, previous to its preparation, he had consulted the very considerable literature on the subject. His presentation is decidedly amateurish in view of the audience addressed.

In a report upon "District Steam Heating," by John W. Glidden, and in a paper on "Salt as a By-Product," by Alex. Dow, some methods whereby central stations may increase their income by the utilization of the so-called by-products are interestingly discussed.

Of all the papers the report in appendix A upon "Decorative and Sign Lighting," by Arthur Williams, is the most elaborate, for it is profusely illustrated by a series of some of the finest half-tones that one could imagine. Undoubtedly, however, the most valuable feature of the volume is the "Question Box," which department should be of immense benefit to the members of the Association, whether as querists or for the general mass of practical information conveyed.

Carcano Power Factor Indicator.

BY GUIDO SEMENZA.

What may be termed a novel feature in the instrument to be described below is that it is rather a power factor meter than a power factor indicator, since it affords a means for taking accurate data; whereas, the ordinary power factor at the present time does not give indications of any great accuracy.

The new instrument is based on a reduction to zero method, which, while not permitting the following of sharp variation, facilitates, on the other hand, the realization of a relay recording apparatus. The instrument comprises a disc which can freely rotate under the action of a shunt and of a series set of coils, in connection with which a special rheostat box is used. The way to proceed in taking measures is as follows:

The rheostatic resistance is varied until the rotating disc is brought to rest, when the values of the resistances give the corresponding value of the power factor; and since to each position of the rheostat there corresponds one value of the power factor, the rheostat is directly graduated in power factor values. The principles on which Mr. Carcano, electrical engineer in charge of the Milan Edison Company's testing department, has designed his method, are as follows:

In an apparatus like the one shown in Fig. 1, consisting of a disc which can rotate under the influence of a revolving field due to a system of coils, the motion will cease the moment all the currents flowing through the different coils have the same phase; therefore, if a number of coils are connected in series in the circuit, and another number of them in shunt, the motion will cease when the current, i, which flows through the coils connected in shunt, are in phase with the current, I, of the principal circuit. Now, for a given shunt coil having such a ratio between reactance and resistance as to cause the current, i, to lag by an angle Θ behind the e.m.f. applied to its ends, such condition will be realized when the principal current, I, lags behind the e.m.f. acting in the circuit, by an angle $\phi = \Theta$. (See Fig. 2.)

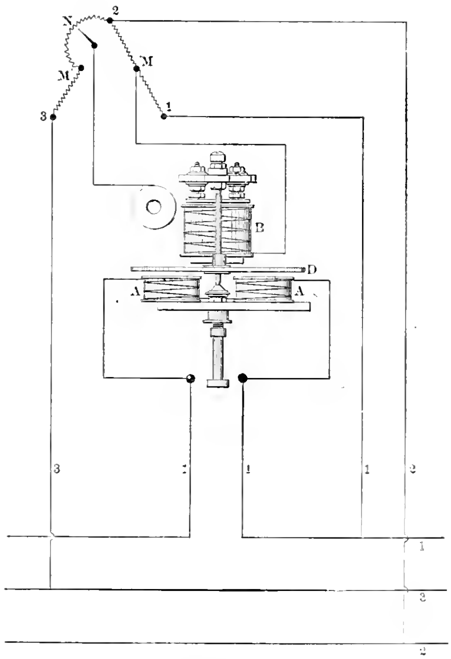

FIG. 1.—DIAGRAM OF APPARATUS.

It follows that if we have at our disposition a coil or a number of coils in shunt, in which the ratio between reactance and resistance, or the angle Θ, can be varied, it is quite possible to balance any value of ϕ. We can, therefore, for any value of the power factor, obtain a zero position of the disc by altering the value of Θ. If the method of altering the angle Θ enables us to know at any moment its value, we can at once read the angle Θ, corresponding to the angle ϕ. It is possible to obtain for any value of ρ the current I in phase with i, without making an alteration in the shunt coils by applying to them, for every value of ϕ, a voltage taken from the opposite points of the circuit, in such a manner that the displacement between such voltage and the principal current is exactly equal to the angle $(\phi - \Theta)$, but of opposite sign. (See Fig. 2.)

In the case of polyphase currents the method is particularly easy and simple. For instance, with three-phase currents, the following arrangement can be applied (Figs. 1 and 3): The ampere coils, A, of the system are put in circuit with the wire, i; B are the coils in shunt; A and B are arranged in such a manner as to produce the rotation of a disc D, so long as a difference of phase exists between

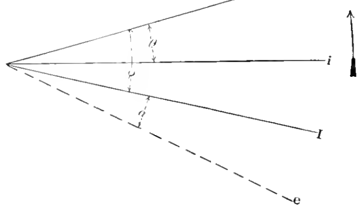

FIG. 2.—ANGLES OF LAG.

i and I, the rotation ceasing when i is in phase with I. Between the wire 1 and 2 of the system a resistance is inserted of which M is the middle point, and between 2 and 3 another resistance is inserted of equal value, but divided in two portions, one being a fixed resistance and the other a rheostat having a certain number of contact points. The shunt coils are connected to M and the sliding handle of the rheostat.

By changing the position of the rheostat we change the phase angle between the e.m.f. acting on the shunt coils and the current I, and the limits of this change are a lag or a lead of 30°. Then the current i, which flows through such coils will vary from a leading value of $30° - \Theta$ to a lagging value of $30° + \Theta$ with respect to I; and through the rheostat N we are able to obtain i in phase with I; or in other words the stoppage of the movable disc for any value of ϕ, comprised between $30° - \Theta$ and $30° + \Theta$, leading or lagging.

As long as i is slightly lagging or leading with respect to I, we will have motion on one or the other direction. In practice the sensibility is very high, since a slight variation in the load of an induction motor arising from its power factor is sufficient to impart a decided motion to the disc, once the position of equilibrium is reached. To every contact point of the rheostat N—that is to say,

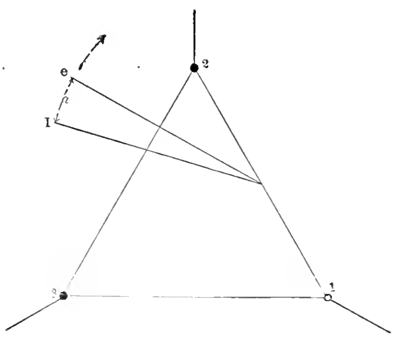

FIG. 3.—DIAGRAM FOR THREE-PHASE CIRCUITS.

to every ratio of the resistance inserted between N and 2 and the one inserted between N and 3—the equilibrium will correspond to a given value of ϕ. In this way a proper graduation or scale of power factor can be established for every value of the resistance, and in practice it will be sufficient to move the contact lever on the contact points forward or backward to obtain the stoppage of the movable disc, and the power factor will be the one shown at the resistance point in contact with the lever.

We thus have an indicating apparatus which can easily also be made a recording apparatus. In fact, if the disc instead of being free is kept to a zero position by a system of springs, and when forced out of such a position, can close the circuit of a relay recording instrument, it is easy to arrange that the motion of the recording pointer will change the position of the rheostat until the disc has taken its zero position. This principle is successfully applied in the Olivetti recording wattmeter.

Mr. Carcano's method and instrument are quite a novelty in the field of alternating-current measurement, and no doubt they will be of great service in testing induction motors and in the control of synchronous motors and converters.

Equipment for New Wanamaker Store.

The huge new Wanamaker department store to be built between Eighth and Ninth Streets on Broadway, New York, will be equipped with one of the largest and most elaborate isolated electric lighting plants in the country. The plant will be a three-wire one and will have many new features. Its capacity will be 1,800 kw. There will be 1,700 arc lights and 6,000 incandescents of 16-cp capacity.

The generators will be six in number, Westinghouse engine type, direct-connected, of 300-kw capacity each. The engines will have a capacity of 450 hp each and are to be horizontal cross compound, automatic cut-off, built by the Buckeye Engine Company, of Salem, Ohio. All couplings are to be made with galvanized iron. The boilers are to be Babcock & Wilcox. The motors will aggregate about 350 hp in capacity. They will be of Westinghouse make and are to range in size from 10 hp to 60 hp. A 10-hp motor and a 25-hp one will be used to drive disc fans, while a 40-hp machine will operate an exhauster. A 20-hp motor will drive a house pump and a 10-hp will work a brine pump. The feeder to the ejecter compressors will be driven by a 20-hp motor. The bilge and drinking water pumps will be 10-hp and 7½-hp motors. A 10-hp machine will drive the temperature regulator, while 25-hp, 45-hp and 60-hp motors will operate fans. The lamps will be operated at 125 volts. The motors will be driven at 250 volts.

An extra heavy conduit will be used in the plant. It will weigh 86 pounds to the 100 ft. The wires will be enclosed in ½-in. pipe, of which there will be several miles. The conduit contract will be undertaken by the Safety Armorite Conduit Company, of Pittsburg, Pa. The panel boards will be of special design.

The Thompson-Starrett Company, 51 Wall Street, New York, have secured the contract for the construction of the building, including the plant. D. H. Burnham & Co., Chicago, are the architects. Mr. Charles Wilks, the Burnham Company's chief engineer, designed the electric plant. The contracts for equipment, etc., are being awarded through H. D. Babbit, the electrical engineer of the Thompson-Starrett Company, who was formerly associated with the Chicago Edison Company. The plant will entail an expenditure not far short of $200,000.

Automobile Parade.

An automobile parade will be made in New York City, April 30, under the auspices of the Automobile Club of America. The head of the parade will start in front of the club house on Fifth Avenue, the officers of the club with their invited guests being in the van. Mayor McClellan will ride at the head of the procession, and at the end of the run he, with other officials, will review the parade from the windows of the club house, after which the parade will disband. The time occupied by the parade will be from one and one-half to two hours. It will start at 2 o'clock promptly, and by 4 o'clock the last car will probably have passed the club house. The parade will be divided into sections, according to the variety of the machines. In the first section will be the guests and club officers, after which will come American gasoline runabouts, American gasoline touring cars, racing cars, foreign gasoline cars, electric runabouts, electric pleasure vehicles, steam pleasure vehicles, electric cabs and hansoms, and commercial vehicles. No notices of any kind will be allowed on the vehicles.

Milne Water-Tube Boiler and Superheater.

The accompanying illustrations show elevations and sections of the Milne water tube boiler, and also in figure to the right, an elevation of the Milne superheater connected to the boiler. The boiler is a simple combination of four parts, namely, an upper and lower drum, connected by a number of sections of 4-in. seamless drawn-steel tubes, arranged in staggered effect, to which is coupled an independent feed water section composed of a single staggered row of tubes. The design, it will be seen, avoids the numerous parts and complications so prevalent in steam boiler practice and reduces the weight of material to a minimum. Materials only necessary to generate steam efficiently are used, and with the best fuel economy.

The tubes are all curved to a five-foot radius. There are five different bends in a complete set of tubes and the front and back rows are interchangeable. The tubes are spaced and arranged so that any of them can be removed and replaced without disturbing the brick work or the tubes adjoining.

The feed water section is composed of a single staggered row of 4-in. tubes, extending completely across the back of the boiler, their upper ends expanded into an independent header, not connected with the upper drum, which receives the feed water. Feed water is not admitted to the upper steam and water drum. This feed water section takes up considerable heat that otherwise would be wasted, as it presents a cool surface to the escaping gases. It also adds another element of safety in protecting the drum plates from the influence of the feed water, particularly in case of low water, and much drier steam is produced, as fluctuations in temperature due to variable feed supply do not occur.

The furnace design and disposition of heating surface will, with intelligent firing, produce the most efficient combustion. The fire brick arch covering the furnace maintains the high temperature required to ignite and burn the fuel gases, and as the heating surface is situated at the back of the furnace and bridge wall, the highest furnace temperature is maintained, and the temperature of the fuel gases not reduced until combustion is completed.

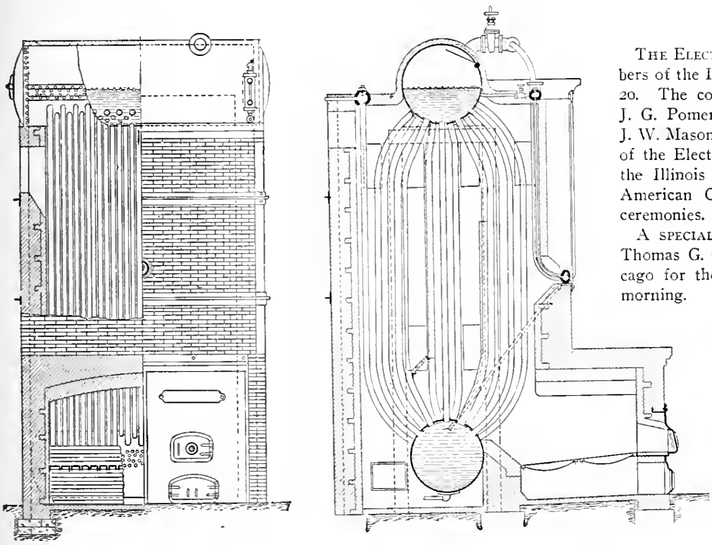
The boiler is constructed of wrought steel material throughout, and does not contain flat, stayed or inaccessible surfaces, all surfaces being cylindrical, of moderate diameters, and accessible in the most direct manner for every purpose. The vertical position of the tubes prevents the collection of dust and ashes, thereby insuring a rapid and uniform transmission of heat; and as the gases of combustion travel about 70 ft. over the heating surface, and finally over the feed water section before escaping, the highest fuel economy is insured.

The tubes can be cleaned with greater ease, and with less expense than straight tubes. Scaffolding or other structures are not needed, and there are no hand-hole plates to remove and replace. One man-hole gives access to every tube in the boiler, and any of the mechanical rotary cleaners, now so extensively used, will clean them in the most direct manner.

The Milne superheater, shown in the figure to the right, is of the most simple form, being composed merely of an upper and lower steel header, into which the superheating tubes are expanded, the flexibility of the system amply providing for expansion and contraction. Being situated in the front of the boiler, it is directly accessible for any purpose, and in case of serious derangement can be removed entirely while the boiler is under pressure. Equally important is the fact that the degree of superheat can be varied to suit all practical working conditions.

The makers claim that the simplicity of the complete boiler and superheater guarantees the greatest ease and efficiency in operation and the lowest cost for maintenance; and that the large water holding capacity and ample steam liberating surface insure steady water level and perfectly dry steam.

These boilers and superheaters are constructed in all sizes up to 1,000 hp and for any steam pressure, the design permitting ample grate area for capacities far in excess of the rating. They are made by the Milne Boiler Company, 95 Liberty Street, New York.



FRONT AND SIDE SECTIONAL ELEVATION OF WATER TUBE BOILER.

Iowa Convention Notes.

THE ELECTRICAL SUPPLY MEN gave a smoker to the members of the Iowa Electrical Association the evening of April 20. The committee in charge of the arrangements were J. G. Pomeroy, of the Adams-Bagnall Electric Company; J. W. Mason, of the Central Electric Company; P. R. Boole, of the Electric Appliance Company, and N. G. Harvey, of the Illinois Electric Company. Thomas G. Grier, of the American Circular Loom Company, acted as master of ceremonies.

A SPECIAL CAR of Chicago supply men arranged for by Thomas G. Grier, W. S. Goll and W. H. Colman left Chicago for the convention Tuesday night, returning Friday morning.

THE NATIONAL ELECTRIC COMPANY, Fort Wayne Electric Works, and Illinois Electric Company made parlor exhibits of light apparatus and specialties.

The following supply and manufacturing concerns were represented: American Steel & Wire Company, American Circular Loom Company, Thomas G. Grier; Allis-Chalmers Company, E. Dryer; American Electric Works, American Transformer Company, P. T. Ackerson; Adams-Bagnall Electric Company, J. G. Pomeroy; Bullock Electric Manufacturing Company, Bryan-Marsh Electric Company, J. S. Corby, J. L. Barnard; Central Electric Company, J. W. Mason, J. G. Ball, C. A. Filker; Crescent Company, Albert Meyer; Crouse-Hinds Company, F. F. Skeel; Columbia Incandescent Lamp Company, J. G. Boyd; Dearborn Drug & Chemical Company, Diamond Meter Company, Electric Appliance Company, P. R. Boole, Leon Bly; Ewing-Merkle Electric Company, Electric Storage Battery Company, J. A. White; Ft. Wayne Electric Works, Garton-Daniels Company, W. P. Cosper; General Electric Company, W. H. Colman, G. A. Seabury; General Incandescent Arc Light Company, Francis Raymond; Gould Storage Battery Company, E. L. Draffen; Guarantee Electric Company, Hazard Manufacturing Company, Heine Safety Boiler Company, James H. Harris; Illinois Electric Company, A. H. C. Dalley, N. G. Harvey, H. W. Johns-Manville Company, F. E. Johnson; Macomber & Whyte Rope Company, Manhattan Electrical Supply Company, W. N. Matthews Brothers, Monarch Electric & Wire Company, New York Insulated Wire Company, Nungesser Electric Battery Company, A. D. Trempe; National Electric Company, A. P. Peck; National Conduit & Cable Company, F. B. Switzer; Nebraska Electric & Fixture Company, A. G. Munro; Nernst Lamp Company, Robert P. Payne; Osborne Flexible Conduit Company, C. B. Roulet, I. A. Bennett; Pass & Seymour, J. S. Jackson; Phelps Company, I. A. Bennett; John A. Roebling's Sons' Company, W. H. Schott, J. C. Hormung; Sawyer-Man Electric Company, A. Sorge, Jr., & Co., E. Emery, George Searing, C. A. Ross; Standard Underground Cable Company, Stanley Instrument Company, F. J. Alderson; Standard Electrical Manufacturing Company, R. W. Loose; Tri-City Electric Company, I. N. Butterworth; Wesco Supply Company; Waterloo Electric Supply Company, L. G. Hopkins; Westinghouse Machine Company, J. B. Wilkinson; Westinghouse Electric & Manufacturing Company, W. R. Pinckard, H. G. Peticolas, Arthur Huntington, A. M. Miller; Western Electric Company, M. R. Lash.

Regulating and Reversing Controllers for Machine Tool Service.

The use of individual motors for driving machinery has grown in general favor as the advantages derived from an independent source of power for each appliance have become recognized. Shunt and compound variable-speed, direct-current motors especially adapted for such service have been designed and suitable controllers for applying the power to the work in hand and properly regulating the speed of the machinery are thus a prime requisite.

A line of controllers, particularly adapted for use with independently-driven machine tools is manufactured by the Westinghouse Electric & Manufacturing Company and known as types V and W, the assortment being comprised of over 600 different sizes and capacities, to cover all the requirements of service. The type V controllers are used upon two-wire, single-voltage circuits, eight forward speeds and four reverse speeds being obtained by resistance in the shunt field circuit. In the type W, used upon three-wire, two-voltage circuits, the speed variations are obtained by means of the two voltages as well as the shunt resistance, provision being made for six forward speeds on the lower and nine on the higher voltage, and six reverse speeds on the lower voltage. Experience has proven that this number of speed variations is the best possible for general use, and affords all the differences in speed required in service.

The type V controllers are ordinarily adopted when a speed variation of 2 to 1 is required, and the type W for variations of 4 to 1, although other variations may be obtained as desired, each installation being separately considered and the controller used which is best adapted to the motor with which it is to be used. The successive intermediate speeds are arranged in practically geometrical progression, but extra leads are provided by the use of which the owner may make such changes as he desires.

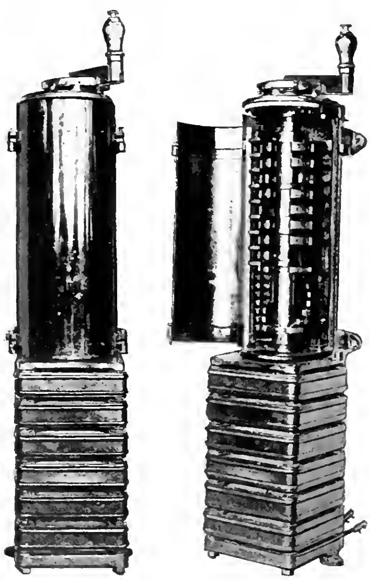


FIG. 1.—CONTROLLER FOR TWO-WIRE, SINGLE-VOLTAGE CIRCUITS.

In general structure, these controllers are based upon the most modern and improved types of Westinghouse design, insuring reliability and long life regardless of hard usage. They are thus practically independent of their surroundings, and give satisfactory service under all conditions. The drum is made of metal and secured to an insulated shaft. The contact strips are of hard rolled copper. The fingers are also made of hard rolled copper and provided with lock nuts and adjusting screws. All parts are liberally proportioned and are made easy of access. The cover can be removed by withdrawing with the fingers the pins which hold it in place, and access to the leads is quickly obtained by removing the strips screwed to the back of the controller. The contacts, the arcing tips on the main contacts and the fingers are easily removed and renewed.

Another important particular which assures the adaptability of these controllers to various conditions is the fact that the handle and ratchet are so designed that they may be removed from the controller and placed at any point which is convenient, and which permits connection to the controller by means of bevel gears and shafting. This not only adapts the apparatus for distant control, but it enables the operator to use the identical handle, ratchet and indicator dial which are furnished with the controller. This not only saves the expense of making a new handle and ratchet, as is necessary with other appliances, but retains the advantages of the peculiarities of the Westinghouse operating mechanism.

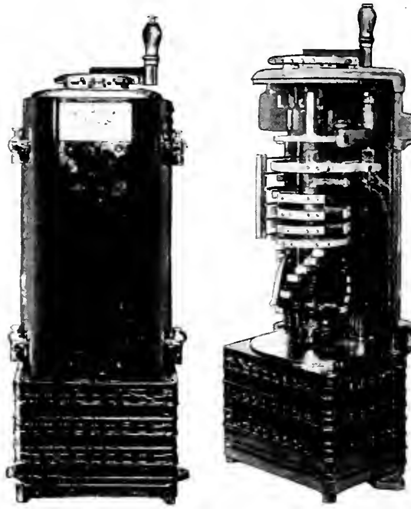

FIG. 2.—CONTROLLER FOR THREE-WIRE, TWO-VOLTAGE CIRCUITS.

The notches in the ratchet are positive, and the design is such that as each step is reached a key drops into a notch and stops the handle, holding it firmly in place until released by a pressure upon the thumb stop in the end of the handle. The operator is thus able to watch his work uninterruptedly while applying power or changing the speed, a fact of distinct advantage.

In the type V controller the starting resistance is inserted when the first contact is made, being cut out when the handle is moved to the second position.

In the type W, a cam lifts from the contact the finger, whose function is to cut out the starting resistance, and thus leaves the resistance in circuit when starting or when changing to a higher or a lower voltage. By means of a dash-pot, the return of the finger is delayed for a predetermined interval of time, the speed of the return being regulated by means of a screw. The checking medium is a non-freezing liquid, greatly superior to air as a means of even and close regulation and not affected by atmospheric conditions. If desired, the dash-pot can be removed without disturbing any other portions of the controller.

Arc shields are placed between all contacts which carry the main current, and in addition all sizes above 10 hp have a powerful magnetic blow-out coil. In capacities to and including 10 hp, the resistance, which is of the imbedded type, is regularly mounted directly beneath the controller. In large sizes it is mounted separately. The leads are conveniently located and have screw connectors.

In every particular these controllers have been designed to give superior service under even the least favorable conditions. They have an unusual amount of strength and durability, and the large assortment insures the adoption of the proper controller to give the best results in every instance.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—The stock market was dull and narrow, trading being entirely professional. The uncertainty as regards the Northern Securities complications is still a factor in the market. The reports of slackness in the iron trade caused weakness in United States Steel preferred. Easy conditions prevailed in the money market, and the demand for time loans was light, plenty of money being obtainable at 4 per cent. Commercial paper was in demand at 4½ per cent., but the supply was only moderate. Toward the end of the week there was a better tone in the stock market. Some strength was exhibited in traction, gas and other specialties. Metropolitan Street Railway was favorably influenced by the prospect of its bidding on some of the new subway work proposed by the New York Rapid Transit Commission. The prices ranged from 110½ to 114⅝, closing at 114⅛—a net gain of ⅜. Fifty-one thousand, nine hundred and eighty shares of this stock were traded in. Brooklyn Rapid Transit was quiet in respect to trading, but it was firmer and closed with a net gain of 1¼ points, the last price being 47½, which was also the highest of the week. General Electric closed at the highest quotation, 164½, and Westinghouse at 158, which represents a net decline of 3 points. Allis-Chalmers common closed at 6½ which was also the lowest point for the week and a net loss of 1⅜, while the preferred closed at 43, the highest figure. The closing quotations and net changes in other stocks in the electric class were: American Telegraph and Cable, 86, a loss of ¾; American Telephone and Telegraph, 126¾, gain ¾; Commercial Cable, 187, loss 2, and Western Union, 88⅞. The curb market showed some activity and firmness, but was irregular. The main interest centred in the newer stocks, Mackey Company shares being freely dealt in. The common showed noteworthy strength, while the preferred reacted several points on what looked like profit-taking sales. Mackey common closed at 24, being a net gain of 4 points, but the preferred lost 3⅞, closing at 134½. The closing prices of the main market, of April 26, are as follows:

TROLLEY AND STEAM.—The statistics of street railways are compared by the *Wall Street Journal*, with the statistics of the steam roads in the United States for the same year. Already the mileage of the electric street railways amounts to 11 per cent. of the steam mileage. The capital stock amounts to 21 per cent.; the funded debt to 13 per cent.; the dividends to 18; and the interest on bonds to 14 per cent. When one remembers that electric street railways are a development of a very few years, and the steam railroads of the United States are a development of three-quarters of a century, this showing seems little less than marvellous. It appears, however, that the total capitalization of stocks and bonds of the street railways amounts to $96,287 per mile, while the total stock, bonds and unfunded debt of the steam railroads amounts to $64,371 per mile. The dividends paid by the electric street railways amounted to 2.5 per cent. of the total outstanding stock, while the dividends paid by the steam railroads amounted to 2.9 per cent., the comparison being for 1902. From this it would appear that the steam railroads are on a better basis, as regards earning power, than the street railways. The latter, however, are essentially passenger traffic lines. In 1902 they carried nine times as many passengers as all the steam railroads of the United States. These, while carrying over 655,000,000 of passengers, nevertheless obtained the bulk of their revenue from the carriage of freight.

CHICAGO EDISON REPORT for the year ended March 31, 1904, is as follows:

	1904.	1903.	1902.	1901.
Gross	$3,837,659	$3,409,576	$2,806,609	$2,517,219
Expenses	2,515,050	2,195,647	1,720,820	1,614,260
Net	$1,322,619	$1,213,929	$1,085,789	$902,959
Charges	307,088	300,900	300,983	279,791
Surplus	$1,015,531	$912,939	$784,806	$623,168
Dividends	720,526	593,346	515,982	477,688
Surplus	$295,005	$319,593	$268,824	$145,480

The general balance sheet as of March 31, 1904, compares as follows:

Assets:	1904.	1903.	1902.
Plants, etc.	$16,940,220	$14,230,840	$12,766,540
Material	326,498	388,025	405,494
Accounts receivable	656,998	784,465	358,997
Cash	262,933	136,035	121,033
Total	$18,186,650	$15,539,365	$13,652,064
Liabilities:			
Capital stock	$9,865,880	$7,589,500	$6,899,900
Advance payment for stock	....	997,357	....
Bonds and debts	6,483,000	5,508,000	5,508,000
Accounts payable	250,130	123,859	140,336
Depreciation reserve	690,000	590,000	500,000
Insurance fund	76,000	68,000	6,000
Surplus account	797,088	610,084	431,077
Open accounts	24,551	52,565	112,751
Total	$18,186,650	$15,539,365	$13,652,064

The allied Commonwealth Electric Company makes the following report:

	1904.	1903	1902.	1901.
Gross	$1,350,999	$1,002,085	$769,666	$629,047
Expenses	834,734	623,264	497,903	410,176
Net	$516,265	$378,821	$271,763	$218,871
Charges	275,737	220,704	167,261	137,770
Surplus	$240,528	$158,117	$104,502	$81,101

The Chicago Edison Company earned 10.2 per cent. on the present outstanding capital, and has declared the regular 2 per cent quarterly dividend payable May 1st. Its gross business increased 12.5 per cent. for the year. The Commonwealth Electric Co. is at present a subsidiary corporation, owning the outlying plants, but in 1911 it will become the successor of the Edison Co. It is now building what will be the largest central station plant in the country, and its business increased 34.8 per cent. last year. The earnings amounted to 3.84 per cent. on the present outstanding capital. In the balance sheet of the Commonwealth Electric appears an item of $32,033 credited to "municipal compensation reserve." The company's ordinance provides that the company shall begin the payment of compensation to the city at the rate of 3 per cent. per annum of the gross receipts after the first five years of the life of the franchise. Compensation began to accrue on June 30 of last year.

DIVIDENDS.—Directors of American Light and Traction Company have declared the regular quarterly 1½ per cent. dividend on the preferred stock, payable May 2. A dividend of 40c. per share has been declared upon certificates of deposit of the Edison Electric Illuminating Company, of Brooklyn, payable May 5. Automatic Electric Company's directors have declared the regular quarterly dividend of 2 per cent. payable May 2. This is the old Strowger Automatic Telephone, which has grown into a big business. American Graphophone directors have declared a dividend of 1 per cent. on the common stock, payable June 15. The Cincinnati Gas & Electric Company has increased the dividend ½ per cent. to 4½ per cent. per annum.

FINANCING LONDON UNDERGROUND.—Speyer & Co. and Blair & Co. offer $10,000,000 5 per cent. profit-sharing secured notes, due June 1, 1908, of the Underground Electric Railways Company, of London, England. The notes are offered at 96½ and interest. This is part of an issue of £7,000,000 sterling, of which $16,650,000 are payable in United States gold. The proceeds of this issue of notes are being used for the construction and equipment of the railways of the Tube Companies, and for electrically equipping the existing lines of the Metropolitan District. The Underground Co. has a capital of £5,000,000 fully subscribed (£2,500,000 paid up). The articles of association provide that Messrs. Speyer & Co., of New York; the Old

Colony Trust Company, of Boston, and Speyer Brothers, of London, shall, during a period of ten years, have the right to nominate a majority of the directors for the time being of the company, thus insuring a continuity of management. Mr. Yerkes says: "There is every probability that all the tube lines will be finished in about two and a half years from the present time. The fact that the power station will be entirely completed leaves us with only the construction of the two lines, and the building of the stations, which can always be pushed along with rapidity. I am happy to say that our expenditures are well within our estimates, which is a condition not often realized."

WASHINGTON, D. C., REPORTS.—The Washington (D. C.) Railway and Electric Company reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.
Gross	$1,400,441	$2,325,755	$2,162,559
Expenses	561,271	1,251,814	1,187,449
Net	$839,170	$1,073,961	$975,110
Other income	....	19,644	16,016
Total income	$839,170	$1,093,605	$991,126
Charges	617,291	892,477	892,477
Surplus	$221,879	$201,128	$98,649

GENERAL ELECTRIC ANNUAL MEETING.—The annual meeting of the stockholders of the General Electric Company will be held at the company's office in Schenectady, N. Y., on May 10, 1904, for the election of directors for the ensuing year.

Commercial Intelligence.

THE WEEK IN TRADE.—The cold weather complaint is still with us. It is interfering with planting preparations and growth, and interrupts outdoor activity in many lines, notably building. Spring trade on the whole is very quiet and collections are slow, although a slight improvement is noted in the latter as compared with previous weeks. All weather and crop reports show the influence of the cold upon plant preparation and growth. In the iron and steel industry the quiet of the previous week has been more pronounced. The demand for deliveries during the second quarter of the year is insistent, but there is an evident hesitation in placing orders for finished products for the remainder of the year. Manufacturers of agricultural implements are the freest buyers. The Pacific Coast lumber trade is still unsatisfactory, but there is report of improvement in general trade. In the eastern markets retail and jobbing trade is rather quiet. There was an increase in business failures during the week ending April 21, as compared with those of the corresponding week last year, the figures for the two periods being 199 and 152 respectively. Copper was dull and featureless, the closing quotations being 13 at 13¼c. for Lake; 12⅞ at 13c. for electrolytic, and 12½ at 12¾c. for casting stock. Activity is noted in the rubber trade.

BIG AUSTRALIAN LIGHTING AND POWER SCHEME.—Australian advices state that an electric light and traction offer has been made to the Victorian Government through the representative of a local company now in London. The gentleman in question, T. Holroyd, manager of the Victorian Light and Power Distributing Corporation, has, according to cabled reports, associated with his company five leading electrical engineering firms in Great Britain, one of which concerns is understood to be the British Westinghouse Electric and Manufacturing Company, Limited. This syndicate has cabled an offer to the Victorian Government to supply the Government and City Councils with electric current at 1d.—two cents—per unit provided not less than 10,000,000 units are consumed annually for at least 10 years. The syndicate intends to generate current from the large coal deposits known to exist between Laverton and Werribee, some seven miles distant from Melbourne. These deposits were tested by Mr. Holroyd's company, who hold options on over 10,000 acres of land. Their proposal is to erect in the vicinity of Laverton, a plant whence the power could be distributed and the consent of a number of municipalities was obtained by the company some time ago. Half their capital being expended in the erection of boring plant, etc., and a large sum being required to carry out the proposals in their entirety, Mr. Holroyd went to London to float a larger company, and the outcome of his visit is the offer before stated. Under their programme, as put forward some time ago, the Victorian members of the syndicate undertook to supply power to private consumers at not more than 8 cents per unit for lighting and not more than 4 cents per unit for power purposes.

THE HENRY R. WORTHINGTON HYDRAULIC WORKS, at the corner of Rapelyea and Van Brunt Streets, Brooklyn, are shortly to be removed to Harrison, N. J., to occupy the new $2,000,000 plant of the International Steam Pump Company, now nearly completed. The Brooklyn site consists of two city blocks, or about four and one-half acres, while the Harrison plant is located on a 35-acre tract and contains 18 acres of floor space. The Worthington Company is one of the oldest and largest manufacturing concerns of Brooklyn, having been founded in 1843 by Henry R. Worthington, the inventor of the duplex steam pump and other hydraulic devices. About 2,000 men are employed in the South Brooklyn works and the new plant at Harrison will accommodate from 5,000 to 6,000 men. The Brooklyn works will probably be sold, the company having already disposed of its large foundries at Elizabethport, N. J. The new plant will employ electric power on a large scale.

NEW ORLEANS LIGHTING FRANCHISE.—A 10-year franchise to date from September 30, 1905, for lighting the public highways, street, squares and parts of the city of New Orleans with electricity and for furnishing electric energy for public buildings for the operation of arc and incandescent lights, motors, pumps, fans, elevators and other public purposes, has been granted by the municipal authorities of the Crescent City to the New Orleans Railway Company, for which concern Sanderson & Porter, Kuhn-Loeb Building, William Street, New York, act as consulting engineers. The franchise calls for the lighting of 476 underground district circuits at $83, and for 2,151 overhead district circuits at $69. It also includes 200,000 kw of power at six cents per kilowatt hour. The company will receive $200,879 per annum for the service.

TELEPHONE EQUIPMENT WANTED.—Mr. M. A. Joy, cotton compress owner, etc., at Camden, Ark., is the proprietor of the Ouachita Telephone Company. It is to be entirely reconstructed, with a central energy equipment of from 300 to 500 central energy visual signal lines, 20 magneto jacks and drops for toll lines, and 300 telephone sets. The construction will include complete new material inside and out, with some 10,000 ft. of cable 25 to 200 pair. The exchange has been in operation for some years and will now be brought up to date. Mr. Joy is in the market to make immediate purchase of this equipment.

MERGER OF SIGNAL COMPANIES.—A negotiation whereby the Taylor Signal Company, of Buffalo, N. Y., and the Pneumatic Signal Company, of Rochester, are to to be merged into one firm, to be known as the General Railway Signal Company, has just been completed. It is capitalized at $5,000,000. Although the officers of the General Railway Signal Company have not been selected, it is said to be settled that W. W. Salmon, of the Taylor Signal Company, will be the executive head of the firm.

MAGNET WIRE COMPANY'S ORDERS.—The Magnet Wire Company, 42 Broadway, has secured a substantial contract from the Massachusetts Electric Companies for magnet, trolley and weather-proof wire. The Pittsburg (Pa.) Coal Company has sent in a fair-sized order for trolley wire. The Cleveland Electric Railway Company has also requisitioned for a fair-sized lot of trolley wire and for magnet and weather-proof. The Interborough Rapid Transit Company has also sent in a good-sized order for specialties.

EQUIPMENT FOR TROY, N. Y., HOTEL.—MacKenzie, Quarrier & Ferguson, New York, have been awarded the contract for the electrical equipment of a large new hotel to be built at Troy, N. Y. and to be known as the Rensselaer. There will be two 75-hp Harrisburg standard engines direct connected to 50 kw generators of General Electric build. The switchboard will be made by the Walker Electric Company, of Philadelphia. The equipment will be used for both lighting and power purposes.

EQUIPMENT FOR CANADIAN SINGER PLANT.—Considerable electrical equipment will be installed in the Canadian plant which is to be built by the Singer Manufacturing Company, of Elizabethport, N. J. The machinery will include a 600-kw generating set and some 200 hp of motors ranging from 1 hp to 5 hp each.

HEINE BOILER ORDER.—The Electric Company of America, Philadelphia, which controls the Auburn, N. Y., Light, Heat and Power Company, has awarded an order to the Heine Safety Boiler Company, New York, offices, Bowling Green Building, for additional boiler equipment for the Auburn plant.

NUEVO LEON WATER POWER SCHEME.—Francisco Garza Trevino, of Monterey, Mexico, has been granted a concession by the government authorities with a view to the construction of a large water power plant on the Rio Ramos, Cadereita district, State of Nuevo Leon. The current will be used for general power purposes.

LIGHTING EQUIPMENT FOR CUBAN PLANTATION.—The Robb Engineering Company, of Amherst, Nova Scotia, represented by G. F. Tremain, 136 Liberty Street, has taken a contract for a 300-hp automatic Robb-Armstrong engine for direct connection to a Stanley generator for lighting a large Cuban sugar plantation.

EQUIPMENT FOR $1,000,000 APARTMENT HOTEL.—Percival Robert Moses, the consulting engineer, 35 Nassau Street, is drawing up plans for the electrical equipment to be installed in a $1,000,000 apartment hotel at 10-14 East Twenty-eighth Street, for C. F. Rogers.

BELL TELEPHONE OUTPUT.—The American Telephone and Telegraph Company instrument statement for the month ended March 31, is as follows:

	1904.	1903.	1902.	1901.
Gross output	126,522	84,286	96,557	76,751
Returned	35,043	38,172	42,847	37,517
Net output	91,479	46,108	53,710	39,234
Total outstanding	3,972,095	3,339,635	2,691,065	2,079,498

The statement for January, 1903, showed a gross output of 129,837, and a net output of 86,551; but this statement covered 42 days, from December 20, 1902, to January 31, 1903. It was in this month that the company changed its system of reporting instrument output so as to cover the calendar months. The net output since the close of the fiscal year December 31, 1903, was 192,578, making total instruments outstanding March 31, 1904, 3,972,095. The indicated gain in the number of subscribers is about 75,000, making the total number of subscribers March 31 in excess of 1,600,000. The indicated gain in the gross earning capacity of the Bell system, at $50 per subscriber, is $3,750,000 per annum; and the indicated gain in net earning capacity is over $1,000,000 per annum. With the number of subscribers now at 1,600,000, the annual gross earnings of the Bell Telephone system will amount to $80,000,000, of which about $23,000,000 is estimated as net earnings.

DE LAVAL TURBINES, ETC., FOR WESTERN PLANTS.—The Turbine Engineering Company, Whitehall Building, Battery Place, New York, recently organized for the purpose of assuming contracts covering the installation of power units and carrying on a general engineering business in addition to acting as exclusive selling agents for the De Laval turbines in Illinois, Missouri, Michigan, Iowa and Indiana, has secured a contract for two De Laval turbine dynamo sets of 200 kw capacity each, direct current, 240 volts, to run condensing, for lighting purposes in the plant of the Anheuser-Busch Brewing Association, at St. Louis. The order has also been taken from the Pfister & Vogel Leather Company, of Milwaukee, for a De Laval turbine dynamo set—the second order—direct current, 250 volts, to run condensing. A 35-kw direct-current turbine dynamo set is also to be put in the Gund Brewing Company's plant at Cleveland, Ohio. A De Laval steam turbine centrifugal pump of 300-hp capacity 4,750,000 gallons per day, to operate against a head of 230 feet, is to be installed at the Ottumwa, Iowa, water works.

MACKAY ENGINEERING COMPANY ORDERS.—The MacKay Engineering Company, Singer Building, New York, has secured a contract for a 40-hp two-cylinder Walrath gas engine to be manufactured by the Marinette Gas Engine Company, of Chicago Heights, Ill., for direct connection to a General Electric generator. This outfit will be used for lighting Calumet Island, St. Lawrence River, Clayton, N. Y. The M. F. Thompson Dry Good Store, at Binghamton, N. Y., is also to be equipped for lighting purposes with a 30-hp, two-cylinder Walrath gas engine. The new Rogers Building, at Fourteenth Street and Sixth Avenue, is to have a number of motors built by the Richmond. Va., Electric Company, for driving centrifugal pumps, MacKay blowers, etc. The Fraser Tablet Company, Eighteenth Street and Eighth Avenue, Brooklyn, has requisitioned for several Richmond motors of 10 hp, 3 hp and 2 hp capacity, and the Wheeler & Wilson Manufacturing Company, 833 Broadway, New York, has ordered some small ones for operating sewing machines.

MILK BY TROLLEY.—Besides handling ashes and building material, and the contract entered into with the Bush Terminal Company for the handling of package freight as already described and illustrated in these pages, Brooklyn Rapid Transit Company has recently entered into arrangements with Borden's Milk Company whereby it will haul this company's milk supply to the distributing stations. It is now hauling beer in the Coney Island section. The Borden Company has taken its milk from the cars in Jersey City by its own teams to its depots in Brooklyn, but hereafter the railroad cars will be floated over to South Seventh Street, and the cans there transferred to the trolleys of the Brooklyn Rapid Transit. Not only will this mean a saving for the milk company and increased earnings for the trolley company, but the milk itself will reach the consumer in better condition. The delivery of beer by trolley in the Coney Island section is giving satisfaction.

WATERTOWN ENGINE ORDERS.—Recent orders for Watertown engines include the following: One 12 & 20 x 14 tandem compound engine for Jacob Ruppert, New York City; two 15½ x 14 high speed engines arranged for direct connection to Sprague generators, for Christian Feiganspan, Newark, N. J.; two 13 x 12 high-speed engines arranged for direct connection to Crocker-Wheeler generators, for Ballantine & Co., Newark, N. J.; two 17 x 16 four-valve engines for F. Wesel Manufacturing Company, Brooklyn, N. Y.; one 17 x 16 four-valve engine, Bloomingdale Bros., Fifty-ninth Street, New York; one 17 x 18 four-valve engine, Railway Steel Spring Company, Oswego, N. Y., this being the fourth order from this concern; one 17 x 18 four-valve engine, Bernardsville Electric Light Plant, Bernardsville, N. J.

THE STERLING ELECTRIC COMPANY, Lafayette, Ind., reports an unusual activity in switchboard work, having contracted for switchboards and additional equipment during the past month for Kansas, Ill.; Newton, Ill.; Hudson, N. Y.; Racine, Wis.; Sheboygan, Wis.; Peru, Ind.; Auburn, Ind.; Russiaville, Ind.; Goldsmith, Ind.; Zionsville, Ind.; Seymour, Ind.; Cairo, Ill.; Clinton, Ill.; Decatur, Ill.; Abilene, Tex.; Albany, N. Y.; Canton, Ill.; Tremont, Ill.; Hoopeston, Ill.; McArthur, Ohio; Chardon, Neb.; Avery, Ind.; Brookville, Pa.; Austinburg, Ohio; Stackbridge, Mich.; Stranghn, Ind.; Sully, Iowa; Webster City, Iowa. The list includes equipments of its well-known boards of common battery multiple, lamp signal magneto, standard Bell type.

THE REEVES ENGINE COMPANY, Trenton, N. J., has just closed with the Drew-Selby Company, of Portsmouth, Ohio, for one of its 400-hp vertical cross compound engines for direct connection to an electric generator. Messrs. Plotner & Stoddard, of Dayton, Ohio, have also purchased a direct-connected 400-hp vertical cross compound. It has sold to the International Steam Pump Company four direct-connected vertical cross compounds. The Trenton Mills and Elevator Company has purchased one of its large vertical cross compounds and it has contracted with the Construction Realty Company to install three simple horizontal engines for direct connection to 65-kw generators, for its new hotel at Broadway and Sixty-ninth Street, New York.

LIGHTING EQUIPMENT FOR TIENTSIN.—Contracts are expected to be let in this market shortly for various equipment to be installed at Tientsin, for the purpose of lighting the British settlement in that Chinese city. The plant will have a capacity of 300 hp. There will be two 100-kw generators direct connected to 13-in. x 14-in. engines. The boilers will be of water-tube type—two units. The street lighting will be done by 250 arc lamps. The export commission house of Muller, Maclean & Co., Centennial Building, 116 Broad Street, whose treasurer, L. E. Phipps, has just returned from the Far East, holds a copy of the specifications, etc.

PHONOGRAPH WORKS BURNED.—The interior of the large four-story building of the Victor Talking Machine Company, at Camden, N. J., was totally destroyed by fire on April 24, causing a loss estimated by an official of the company at nearly $500,000. The concern carried an insurance of $250,000. Upward of 50,000 phonographic disk records and 25,000 talking machines in various stages of completion were destroyed. Thousands of original records, which cannot be replaced, were also ruined. A fireboat and four fire companies from Philadelphia assisted the Camden Fire Department in preventing the flames from spreading.

JALISCO WATER POWER PROJECT.—A fair-sized hydraulic plant is to be built on the Rio Grande de Santiago, municipality of Hostotitaquillo, State of Jalisco, Mexico. Francisco Brenna, of Mexico City, has secured the necessary concession from the Secretary of Fomento. The franchise permits of the utilization of 15,000 liters of water per second. The power is to be generated principally for lighting towns in the vicinity.

EQUIPMENT FOR APARTMENT HOTEL.—The apartment hotel which is being constructed at Sixty-ninth Street and Broadway, is to be equipped for lighting purposes with three 13-in x 12-in. simple engines of Reeves build direct connected to 65-kw C. & C. generators. Percival Robert Moses, 35 Nassau Street, is the consulting engineer.

WESTINGHOUSE EQUIPMENT FOR CANTON PLOW PLANT.—The contract for the additional equipment—500 hp—to be installed in the big agricultural implement manufacturing plant of the Parlin & Orendorff, at Canton, Ohio, has been allotted to the Westinghouse Company.

MONTAUK FIRE DETECTING SYSTEM FOR AUSTRALIA.—The Montauk Fire Detecting Wire Company, American Surety Building, New York, has just received a large Australian contract by cable for its specialties to be installed in one of the principal Melbourne theatres.

EQUIPMENT FOR MEXICAN MINES.—An American syndicate in which William M. McCord and Lucien M. Fairbanks, of Chicago, Ill., are largely concerned, is about to erect a large electrically operated mill at the Peregrino mines in the Guanajuato district, Mexico.

GENERAL ELECTRIC DESK FANS FOR EGYPT.—The General Electric Company has secured a substantial contract for desk fans for export to Alexandria, Egypt. The order was secured through the export commission house of Muller, Maclean & Co.

General News.

THE TELEPHONE.

TRINIDAD, COL.—The Colorado Telephone Company has moved into its recently completed new building, and the overhead wires have been placed under ground. The equipment of the new building is of the most modern design. About $100,000 was expended by the company in these improvements.

PEARL CITY, ILL.—The Farmers' Mutual Telephone Company has been organized here with L. C. Hollister as president.

CAMPUS, ILL.—The Campus Telephone Company has been incorporated with a capital stock of $2500. A. J. Harrington is one of the directors.

ASSUMPTION, ILL.—A new telephone company has been formed here. Among those interested are Ray Johnson, Dennis Keating and others.

DUVAL, ILL.—The Okawa Township Telephone Company has been incorporated with a capital stock of $2500 by William Hendricks, G. L. McCullough and Alex Roberts.

NEW HOLLAND, ILL.—The New Holland Telephone Company has been incorporated with a capital stock of $2,500. The directors are J. W. Collins, P. E. Kuhl and L. C. Schwerdtfeger.

SUMMITVILLE, IND.—The Farmers' Rural Telephone Company has been incorporated with a capital stock of $5000. F. P. Thurston, G. W. Webster and others are the incorporators.

RANDALL, IA.—The Martin Telephone Company will install a new switchboard here.

STORY CITY, IA.—The Gilbert and Story City Telephone Company has been formed to build a rural line.

PLYMOUTH, IA.—The Plymouth Telephone Company has been incorporated with a capital stock of $10,000.

OXFORD, IA.—The Eastern Iowa Telephone Company has been incorporated with a capital stock of $100,000.

FOREST CITY, IA.—The Farmers' Co-operative Telephone Company has been organized with G. A. Faber as president.

CHASE, KAN.—The Chase Telephone Company has been incorporated with a capital stock of $5000.

ENGLEVALE, KAN.—The Englevale Telephone Company has been incorporated with a capital stock of $5000.

FRANKFORT, KY.—The Allen County Home Telephone Company has been incorporated with a capital stock of $2500. A. M. Haines and S. F. Cornwell, of Hainesville, are the incorporators.

NORTH ATTLEBORO, MASS.—A new telephone building is to be erected here for the Providence Telephone Company.

COLDWATER, MICH.—The Wolverine Telephone Company has been organized here.

SOUTH HAVEN, MICH.—The Kibbie Telephone Company will build a line from South Haven to Covert.

EAST AMBOY, MICH.—The Dutch Street Telephone Company has been incorporated. J. B. Dick is president.

HINKLEY, MINN.—The Hinkley & Rural Telephone Company has been formed to build lines in this vicinity.

AUSTIN, MINN.—The Tri-State Telephone Company will build a long-distance line from this place to Lacrosse, Wis.

ANOKA, MINN.—The Potato Belt Telephone Company has been incorporated with a capital stock of $20,000. R. J. Dyer is president.

HATTIESBURG, MISS.—The Cumberland Telephone Company has petitioned for a franchise in this place, but there is considerable opposition to granting the same. There is a local system in operation which is controlled by local capitalists. The latter are willing, however, that the council grant the Cumberland company the privilege of establishing a long distance station here.

BIG TIMBER, MONT.—A co-operative telephone company has been organized here to construct a telephone line between Big Timber and Melville, a distance of 45 miles. B. O. Felland is president; E. H. Ellingson, secretary, and D. O. Clack, treasurer.

CHARLESTON, MO.—The Southeast Missouri Telephone Company has been incorporated with a capital stock of $150,000. The directors are M. Moore, J. E. Armstrong and others.

MOBERLY, MO.—The Cairo Telephone Company has elected officers as follows: President, Harry McKinney; vice-president, F. Haines; secretary, John Boucher; treasurer, J. W. Stigall.

ST. LOUIS, MO.—The Kinloch Telephone Company will install in the Palace of Electricity at the Exposition a "model" telephone exchange. The switchboard is for 1000 lines, and instruments will be placed in all of the World's Fair buildings and in all parts of the grounds.

CHARLESTON, MO.—The Southeast Missouri Telephone Company has been incorporated to establish and operate telephone exchanges at Charleston, Sikeston, Dexter, Melden, Campbell and Bloomfield. The capital stock is $150,000. The incorporators are J. Handy Moore, Paul B. Moore, Mary Moore, J. E. Armstrong and R. B. Boyce.

LINCOLN, NEB.—The Dewitt Telephone Company has increased its capital stock to $20,000.

EGG HARBOR CITY, N. J.—The Egg Harbor Telephone Company has been organized with a capital stock of $3000 by L. Krevin, W. G. Shottman, G. W. Otto and Charles Oberuder.

PENNINGTON, N. J.—The Pennington Telephone Company has been incorporated with a capital stock of $5000. The incorporators are: William H. Bogart, Jerry F. Crowerly and Joseph F. Harris.

NEWARK, N. J.—The Newark Telephone Exchange has been incorporated with a capital stock of $25,000. The new company has purchased the local telephone system established and operated by Mr. William H. Kelley. The exchange has 220 telephones. The directors of the new company are: William H. Kelley, John E. Pulver, Ernest A. Smith, Edward P. Thatcher, J. P. Ballou, F. D. Burgess and Albert Proseus.

WOLCOTT, N. Y.—A new telephone company is being organized here with E. T. Phillips as president.

COOPERSTOWN, N. Y.—The Cooperstown Telephone Company has increased its capital-stock from $7,000 to $10,000.

CORTLAND, N. Y.—The Empire State Telephone Company has asked permission of the council of this place to place its wires in underground conduits.

DUNDEE, N. Y.—The Dundee, Himrod & Dresden Telephone Company is being organized here to build a line from this place to Himrod and Dresden. Mr. Henry C. Harbending, of Dundee, is interested.

SARATOGA, N. Y.—The Commercial Union Telephone Company has arranged to purchase the property and rights of the Saratoga Telephone and Telegraph Company, the Rensselaer Telephone and Telegraph Company, of Troy, and the Union Telephone Company, of Glens Falls. Each of the individual companies has voted in favor of the consolidation.

FAIRMOUNT, N. D.—The Farmers' Telephone Company will be incorporated with a capital stock of $6000.

STRUBLE, OHIO.—The LaMars Telephone Company has been granted a franchise.

SPRINGFIELD, OHIO.—Prominent citizens are organizing an association favoring the use of one telephone system. They think that two are a nuisance.

CENTERBURG, OHIO.—The Central Ohio Telephone Company has been incorporated with a capital stock of $10,000. The directors are: T. P. Sylvan, E. E. McGuire and others.

COLUMBUS, OHIO.—The Preble County Telephone Company has been incorporated with a capital stock of $25,000. The incorporators are: John C. Stover, J. E. Flora, A. M. Fudge and J. S. Steward.

EAST LIVERPOOL, OHIO.—The Winona Central Telephone Company has commenced the construction of an exchange in Dungannon. It will take care of 40 or 50 telephones to begin with. The company will build another trunk toll line to Lisbon.

CLEVELAND, OHIO.—President Dickson, of the United States Telephone Company states that he has secured $150,000 of new money for use in the development and extension of the long distance lines of the company. The money will be used in connecting the United States system with those of the Indianapolis, St. Louis and Pittsburg independent systems.

CLEVELAND, OHIO.—President F. S. Dickson, of the Cuyahoga Telephone Company, states that since the new switchboard was installed two months ago the company has been gaining new subscribers at the rate of 15 per day. The company is now earning the dividend on its preferred stock and piling up a surplus that will be used for future improvements. President Dickson denies that the company will pay a dividend on common stock as reported in the daily press recently.

LINTLEYVILLE, PA.—A new telephone company has been organized here with A. N. Both as president.

PHOENIXVILLE, PA.—The Phoenixville Telephone Company has been organized here by E. C. Meier, William Ellis and others.

PHILADELPHIA, PA.—The Keystone Telephone Company's April directory is said to contain the names of some 14,500 subscribers, an increase of 1,500, more than 10% over the January directory. The number of nearby outside connections has also increased about 10%. The Atlantic City line of the company will open about May 15, making connection with the Atlantic Coast Telephone Company, a subsidiary of the Interstate Telephone Company, which has 1,600 subscribers in Atlantic City.

GRANITEVILLE, S. C.—A local telephone company has been organized here and will install the Clark automatic system. Arrangements have been made with the Southern Bell Telephone Company for long-distance connection. The new company has been incorporated with a capital stock of $3000, the officers being W. A. Giles, president and treasurer; Rev. Graves L. Knight, T. H. Rennie and W. A. Giles, board of directors.

NASHVILLE, TENN.—The Western Dixie Telephone Company, of Henry County, has been incorporated with a capital stock of $1,000. The directors are H. A. Liles, A. Turner and others.

SALT LAKE CITY, UTAH.—The management of the Rocky Mountain Bell Telephone Company announces that it will expend about $150,000 in the next few weeks in improvements to its system in Salt Lake.

OSHKOSH, WIS.—A. B. Ferdinand again seeks a franchise for an independent local telephone exchange.

EAU GALLE, WIS.—The Eau Galle Telephone Company has been incorporated with a capital stock of $5000. The directors are: C. G. Billings, Wm. Stoops and others.

MINERAL, WIS.—The Willow Springs Telephone Company has been incorporated with a capital stock of $4000. The directors are: J. P. Sheldon, R. M. Phillips and others.

ROBERTS, WIS.—The Roberts Telephone Company has been incorporated with a capital stock of $5000 by A. Turner, R. C. Andrus, George A. Turner, David Imrie and A. J. Walker.

SOUTH WAYNE, WIS.—The Crosby & Blaisdel Telephone Company, of South Wayne, Lafayette County, has been incorporated with a capital of $25,000. The incorporators are: A. N. Crosby, W. C. Blaisdel and W. R. Bixby.

Electric Light and Power.

DEMOPOLIS, ALA.—The Demopolis Electric Light & Power Company contemplates an extension to its plant. A new brick engine room will be built. Mr. A. R. Smith, of Demopolis, is manager.

MALVERN, ARK.—The Malvern Light & Power Company contemplates the installation of a new dynamo and boiler. Mr. C. W. Turner, of Malvern, is president and manager.

PINE BLUFF, ARK.—The Pine Bluff Light & Water Company will install a new alternating current generator and direct-connected engine. Mr. Robert York, Pine Bluff, is manager.

VASALIA, CAL.—The Mt. Whitney Power Company is installing a second power plant containing three 500-kw units which are driven by Stilwell-Bierce and Smith-Vaile turbines. Mr. B. M. Maddox is manager.

WATSONVILLE, CAL.—The Big Creek Power Co. of Santa Cruz will purchase property in this city as a site for a plant to furnish the local circuit with electric power. About $100,000 will be spent in improving the service here.

LODI, CAL.—The Northern San Joaquin Electric Company has absorbed the Lodi Electric Works. The new company will give its patrons a continuous service. At the present time the lights are turned on at dusk and shut off at twelve o'clock.

LOS ANGELES, CAL.—The Los Angeles Gas Company and the Los Angeles Electric Company have been merged into a single corporation with a capital stock of $4,000,000. A meeting of the stockholders of the concerns is announced for April 27 to perfect the plans of consolidation.

MONTROSE, COL.—The Montrose Electric Light & Power Co. has secured a new site for an electric power, cold storage and ice plant to be constructed here this summer.

GLASTONBURY, CONN.—The Glastonbury Power Company has been incorporated in this State with an authorized capital stock of $350,000. The company proposes to develop the water power of Roaring Brook for electrical purposes. The project calls for an immediate development of 1,600-hp. The incorporators of the company are Lewis W. Ripley, Henry S. Goslee, D. W. Williams, James S. Williams, J. H. Hale and Frank D. Glazier.

WASHINGTON, D. C.—The Potomac Electric Power Company will, during the coming summer, put underground its 73,820 feet of overhead electric wires. The cost for this improvement is estimated at $16,000.

WASHINGTON, D. C.—Bids will be received May 3, at the Bureau of Supplies and Accounts, Navy Department, Washington, for furnishing at the navy yards, Portsmouth, N. H., Boston, Mass., and Newport, R. I., a quantity of arc lamps, switch boxes, conduit and fittings, copper wire, electrical supplies, crucible steel wire and other material. H. T. B. Harris, Paymaster Gen., U. S. N.

JACKSONVILLE, FLA.—Bids are wanted May 4 for furnishing f.o.b. cars at Jacksonville a 500-kw generator, together with exciter and switch panels; turbine to be worked condensing at 150 lbs. steam pressure; 27-in. vacuum; generator to be three phase, 60 cycle, 2,300 volts; makers must guarantee efficiency to be equal to first-class Corliss engine; also for surface condenser complete for above turbine, with separate water and dry vacuum pumps. For further information apply to R. N. Ellis, superintendent of water works and electric light plant.

ELGIN, ILL.—The Fox River Light, Heat & Power Company, of Elgin, Ill., it is stated, has purchased the Aurora, Elgin and Chicago Power Company from the Aurora, Elgin and Chicago Railway.

O'FALLON, ILL.—The O'Fallon Electric Light, Power, Heat & Water Company is changing its arc light system over to the alternating current system. Mr. G. W. Tidemann is president and superintendent.

NEVADA, ILL.—The Nevada Electric Company has let the contract for the extension of its power station. The electrical apparatus will be supplied by the Westinghouse Company and the engine by the Murray Iron Works, of Burlington.

QUINCY, ILL.—The Quincy Gas & Electric Company will extend its power plant in this city. A larger boiler, a new 2000-hp engine and a new General Electric generator will be installed. The improvements will cost $25,000. Mr. H. O. Channon is superintendent of the electric light plant.

NOBLESVILLE, IND.—The city council is asking for bids for a ten-years' contract to light the city.

NEW HARMONY, IND.—Bids are wanted May 16 for furnishing material and constructing an electric light plant.

FLORA, IND.—It is proposed to construct water works and an electric light plant, at a cost of $20,000. Address M. W. Eaton is president town board.

FT. WAYNE, IND.—The Ft. Wayne Electric Light & Power Company has completed its organization and will at once begin the reconstruction of its plant.

JASPER, IND.—The local electric light plant has been purchased by the town board for $7,000. The town will make extensive improvements and betterments.

BOONVILLE, IND.—The City Light & Power Company has been incorporated with a capital stock of $12,000, by J. F. Katterjohn, John E. Madden, Dorsey Reed, Louis J. Meyer and William Roth.

NEWBURY, IND.—The Newbury Electric Light & Power plant will install some new apparatus during this year, including a generator, engine and boiler. A water works system will also be introduced. Mr. G. F. Lacke is the owner.

ROANOKE, IND.—The town council has made arrangement with the Ft. Wayne and South Western Traction Company for electric lighting for the streets and business houses. The company will move a sub-station now a mile east of Roanoke to the city and will build another sub-station.

ARDMORE, IND. TER.—The Ardmore Ice, Light & Power Co., of Ardmore, has been incorporated with a capital of $125,000, by A. Ruemmeli, of St. Louis, Mo.; Henry Brann and L. P. Anderson, of Ardmore, and others.

WINFIELD, KAN.—The citizens have voted to issue $30,000 bonds for electric lighting.

GREAT BEND, KAN.—The Grimes Light, Telephone & Power Company will install another alternator before next fall.

BALTIMORE, MD.—A strong fight is being made in the city council for and against the petition of the Maryland Telephone Company for an electric light franchise. Mayor McLane a few days ago received a petition 24 yards long and containing over 1,500 signatures of corporations, firms and individuals who asked that the ordinance be passed. The ordinance has already passed the second branch of the city council and is now before the first branch for consideration.

WESTFIELD, MASS.—An appropriation of $10,500 has been voted by this town for a new electric power plant, and $1,000 for motors for use in heating and ventilating school buildings.

EATON RAPIDS, MICH.—The citizens have voted to issue water and lighting bonds.

KALAMAZOO, MICH.—The Kalamazoo Valley Electric Co. will soon begin the construction of a power plant at Ceresco on Kalamazoo River, at an estimated cost of $200,000.

ALLEGAN, MICH.—The Allegan Light & Power Company's plant has been sold to Messrs. S. Baker, H. A. Delano, George E. Delano, of Otsego, and F. M. Van Auken of Allegan. The change will take effect on May 1. The price paid is understood to be about $15,000. It is stated that the Kalamazoo Valley Electric Company will ask for a franchise to do commercial and domestic lighting in this city.

FARIBAULT, MINN.—The Faribault Gas & Electric Co. contemplates the installation of improvements at its manufacturing plant, and engineers are now figuring on the best methods of installation, probable cost, etc. Among the many improvements under consideration is the installation of a steam turbine.

CHARLESTON, MO.—The Southwest Missouri Ice, Light & Power Co. has been incorporated with a capital of $100,000. J. E. Armstrong and R. B. Boyce, of Charleston, are among the incorporators.

ROSWELL, N. M.—A franchise has been granted to Maynard Gunsul to furnish electricity for power, heat and illuminating purposes in this city.

CORTLAND, N. Y.—It is stated that the Cortland & Homer Electric Co. is to improve and enlarge its plant.

SAG HARBOR, L. I., N. Y.—Bids will be received by the Village Trustees until May 3 for $24,000 electric light bonds.

GOUVERNEUR, N. Y.—The Village Trustees have granted J. Henry Abbott a franchise for an electric light plant.

MANLIUS, N. Y.—The Manlius Gas & Electric Co. has been incorporated with a capital of $10,000. M. Murphy and Wm. Murphy, of Manlius, and G. M. Corwin, of Oswego, are the directors.

KING'S PARK, N. Y.—The contract for installing new electric conduits and cables in buildings at the Long Island State Hospital here has been awarded to the Commercial Construction Co., New York City, for $5,235.

KINGSTON, N. Y.—Contracts have been awarded for the construction of a complete power plant and water works at the home of Colonel Astor at Ferncliff. The electrical equipment will include two 50-kw turbo-generators and a storage battery outfit.

NEW YORK, N. Y.—Bids will be received May 3, at the Bureau of Supplies and Accounts, Navy Dept., Washington, D. C., for furnishing at the navy yard here a quantity of electric motors, batteries, incandescent lamps and other material. H. T. B. Harris, Paymaster Gen., U. S. N., Washington, D. C.

WAYNESVILLE, N. C.—Engineers Ladshaw & Ladshaw, of Spartanburg, S. C., have received the contract for developing 1,000-hp on Pigeon River for B. G. Sloan, proprietor of the White Sulphur Springs Hotel. This power will be transmitted to Waynesville, N. C., and will be used for lighting and other purposes. W. C. Willard will have charge of the field work in the development at Waynesville.

VALLEY CITY, N. D.—At the recent city election the proposition to sell the electric light plant was not carried.

MOOSE JAW, N. W. TER.—Bids will be received May 14 by W. A. Munns, secretary and treasurer, Moose Jaw, for electric lighting equipment and engines. Willis Chipman is chief engineer, address 103 Bay St., Toronto, Ont.

NAPOLEON, OHIO.—Bids are wanted May 3 for $25,000 water and light enlargement bonds. E. W. Hilgendorff, is village clerk.

DAYTON, OHIO.—The Board of Public Service has adopted the report of the light committee and the city solicitor declaring the legality of the contract between the city and the Dayton Electric Light Company. It was noted in our issue of April 16 that Mayor Snyder had vetoed the ordinance granting the franchise.

WILMERDING, PA.—The Wilmerding Electric Light Co. is reported to have purchased a site on which it is proposed to construct a power plant.

SHENANDOAH, PA.—At a meeting between the stockholders of the People's Light, Heat & Power Co., of Shenandoah, and the People's Light, Heat & Power Co. of Mahanoy Township, it was agreed to merge the two companies into one and erect a plant with power enough to furnish light, heat and power for Shenandoah, Mahanoy City and other towns nearby. D. M. Graham is president.

BRYAN, TEX.—H. B. Dorsey writes that later on he may be in the market for electrical equipment for a lighting plant.

SHERMAN, TEX.—The Sherman Light & Power Co., of Sherman, has been incorporated with a capital of $100,000. Incorporators: M. B. Pitts, W. R. Brents and C. N. Roberts.

CASTLEDALE, UTAH.—W. E. Raines, of the Salt Lake Electric Supply Co., Salt Lake City, has submitted figures to the town boards of Orangeville and Castledale for an electric light plant to be used for lighting both towns. The probable cost will be $10,000

DAYTON, TENN.—The Dayton Lighting & Power Company is rebuilding its plant in this place.

WOODSTOCK, VA.—The Woodstock Electric Light & Power Company has been incorporated with a capital stock of $2,000 to $10,000.

VANCOUVER, WASH.—The Department of Columbia has decided to install electric light at the post here. The Vancouver Electric Light Company will probably receive the contract for a term of years. Arrangements are being made to purchase a new 500-hp engine to supply the required power.

SPOKANE, WASH.—George Nixon has been awarded the contract for the complete installation of the Waterville transmission plant. The available water power on the Enteat river is 3,000-hp, and the present development is for 250-hp. Three-phase current at 6,600 volts will be transmitted to Waterville, 9 miles distant.

WESTON, W. VA.—The Weston Electric Light, Power & Water Company will double the capacity of its plant during the coming summer and will install either a turbine or gas engine, direct-connected.

FENNIMORE, WIS.—The City Council has decided to install an electric light plant in connection with the city water works.

FOUNTAIN CITY, WIS.—Messrs. H. and F. Roettiger, owners of the electric light plant here, propose to install another dynamo.

HARTFORD, WIS.—The Hartford Electric Company may get the contract for street lighting, in which case its plant will have to be remodeled.

EAU CLAIRE, WIS.—The question of constructing a municipal electric light plant is under consideration. Emmet Horan is chairman of the committee.

WAUSAU, WIS.—The Hackworthy Construction Co., of Appleton, has secured the contract for building the new electric light plant at Wausau, for about $20,000.

ST. FRANCIS, WIS.—The board of directors of the St. Aemilianus Orphan Asylum has voted to install a new electric light plant including generating outfit and probably some changes in the heating system. George W. Colles, of Milwaukee, is engineer.

MANITOWOC, WIS.—The West Side Electric Power & Lighting Company has been organized with a capital of $25,000. A large plant will be erected here, which will be equipped by the Milwaukee Electric Co. Incorporators: Wm. Rahr, Sr., and Wm. Rahr, Jr.

THE ELECTRIC RAILWAY.

WOODBURY, CONN.—The Woodbury & Seymour Street Railway Company will establish an electric lighting plant and has developed for that purpose a water power.

MIDDLETOWN, CONN.—The franchise of the East Lynne Street Railway Company has been purchased by Morgan & Phelps, a New York firm. The company will be capitalized at $150,000. The new owners are having surveys made, after which the contracts will be let.

CHICAGO, ILL.—The contract has been let to the Arnold Electric Power Station Company, of Chicago, for the new power station of the Chicago & Milwaukee Electric Railway at Highwood, Ill. The building will cost about $150,000 and the equipment will include Allis-Chalmers engines, the electrical apparatus being of the General Electric Company's make.

BLOOMINGTON, ILL.—The stockholders of the Bloomington-Lincoln-Springfield-Peoria Interurban Company held their first annual meeting here a few days ago. The newly elected directors elected the following-named officers: President, La Fayette Funk; vice-president, S. E. Prather. A preliminary survey and the securing of right of way will be undertaken at once.

ALEXANDRIA, IND.—The promoters of the Oil Belt Traction Company are having a survey made of the line to connect Alexandria, Hartford City and Celina, Ohio.

MOORESVILLE, IND.—The Town Council is attempting to extend the city limits so as to include the power house and car houses of the Indianapolis & Martinsville Traction Company for taxation purposes. The company has $100,000 worth of machinery in the power house. It is said the company has threatened to dismantle and remove the power house if the town limits are extended.

CLINTON, IA.—The State Electric Street Railway Company has been granted a franchise and will spend $150,000 in rebuilding and equipping the line. The Illinois & Iowa Company has let contracts for power and operating equipment.

NEW ORLEANS, LA.—An ordinance has been introduced in the City Council of New Orleans authorizing the sale of a franchise for the construction of an electric railway in Algiers.

NEW ORLEANS, LA.—At a special meeting of the New Orleans & Carrollton Railroad Light & Power Company and the St. Charles Railroad Company it was separately decided to grant to the New Orleans Railways Company a lease of their properties until 1962. The lease will not be executed, however, until the injunction now pending against such action has been dissolved.

SKOWHEGAN, ME.—The Skowhegan & Norridgewock Electric Railway has been sold at auction to Amos K. Butler for $10,500. This road was built in 1894 at a cost of $56,000, and over $10,000 has been expended on it since. The town has $10,000 worth of stock.

WORCESTER, MASS.—The Boston & Worcester Street Railway Company is installing two 500-kw rotaries, one at the South Framingham power station, the other at the Westboro sub-station.

NORTH ADAMS, MASS.—Vice-President A. H. Rice, of the Hoosac Valley Street Railway Company, will, on May 1. it is announced, succeed Col. F. S. Richardson as president. The directors have voted to ask for authority to increase the capital stock by $100,000.

WORCESTER, MASS.—At the annual meeting of the Worcester & Webster Street Railway Company the following officers were elected: Edgar S. Hill, president; J. B. Potter, treasurer; Harry E. Back, clerk; the above and George A. Carmichael and W. F. Little, Worcester; E. N. Sanderson, New York; Harry E. Back and Samuel Anderson, of Danielson, Conn., directors. The general statement was made that the company has had a successful year. The company's property is used as a portion of the Worcester & Connecticut Eastern Railway Company.

GREENWOOD, MISS.—A meeting of the incorporators of the Greenwood Electric Railway Company was held here. A temporary organization was perfected and the subscription books closed. The officers elected were Gen. Monroe McClurg, president; Samuel J. Stein, first vice-president; Richard T. Jones, second vice-president; Rowan Thayer, secretary and treasurer; H. G. Kitchell, consulting engineer. A part of the capital was paid in, and the work will be given immediate attention.

JEFFERSON CITY, MO.—The Lexington & Suburban Railway Company, of Lexington, has been chartered with a capital of $250,000, owned chiefly by Mr. Gustave Haerle, of Lexington. The other stockholders are G. Hedrick, A. G. Sutherland, L. R. Ash and V. H. Cochrane, of Kansas City. The road is to be 25 miles in length, and will be run from Mayview.

TOLEDO, OHIO.—The Toledo & Northwestern Railway Company has been incorporated, with $10,000 capital stock, by C. W. Merrill, J. O. Ormond, R. W. Barton, Walter Gayhart and H. C. Adams.

WAUSEON, OHIO.—Samuel A. Wright, president of the Ohio Northern Traction Company, has obtained a franchise for the line through Wauseon. The road will extend from Adrian, Mich., to Defiance, Ohio.

WEST ALEXANDRIA, OHIO.—The Dayton & Western Traction Company is extending its power station at this place. The new equipment will include two 450-hp Hamilton-Corliss engines, two 250-kw generators and two 250-hp boilers.

TOLEDO, OHIO.—It is said that William Ford, of the Ohio & Michigan Traction Company, has just succeeded in floating the company's bonds to the extent of $4,500,000 in New York. The company proposes to build to Ann Arbor, Mich. Hirsch & Company are said to have taken the bonds.

TOLEDO, OHIO.—The Toledo Railways & Light Company is extending the boiler house at its main station in this city. A new smokestack will be erected. The Ricard Boiler Company, of Toledo, has been given the contract for four 650-hp water tube boilers. The plant will be equipped with automatic stokers, coal conveyors, etc., for the latter of which contracts have not yet been given out.

COLUMBUS, OHIO.—The Ohio Union Traction Company, the title of the company under which it is proposed to consolidate the various Appleyard interests in Ohio, has increased its capital stock from $10,000 to $700,000. This is to cover the mortgage recently given on the proposed new line from Findlay to Kenton, the last link required to complete the system between Cincinnati and Toledo.

GREENVILLE, PA.—S. G Bailey, of Pittsburg, has applied to the Borough Council for a street railway franchise.

HARRISBURG, PA.—Col. P. Russ, of this city, has a force of engineers surveying for the proposed electric railway from Mount Holly Springs to Gettysburg, a distance of about 22 miles.

COATESVILLE, PA.—Borough Council has passed the ordinance transferring the rights granted the Brandywine Electric Railway Company to the Philadelphia, Coatesville & Lancaster Street Railway Company.

CHAMBERSBURG, PA.—An extension of the town line of the Chambersburg & Gettysburg Electric Railway Company to Wilson College, a short distance from town, will be built this summer. The company's power house will be ready by June 1.

WASHINGTON, PA.—Ordinances asking for franchises for a proposed electric railway to connect Washington with Pittsburg will be introduced at the next meeting of Council. The line will connect with the Pittsburg & Charleroi line at Liberty, in Allegheny, and will be 15.4 miles long. The line is to form a link in a trolley system from Pittsburg to Wheeling.

LITTLE COMPTON, R. I.—The Town Council of Little Compton has granted to the South Shore Street Railway Company a franchise to lay rails and operate a railway in the town.

ANDERSON, S. C.—This place is to have an electric railway. J. A. Brock, R. S. Ligon and others are the promoters. One hundred thousand dollars is the estimated cost. The line will be extended to the mill villages, near the city.

SAN ANTONIO, TEX.—The San Antonio Traction Company contemplates making extensive improvements in its lines. Chief among these will be the rebuilding of the entire West End line. The making of these and other improvements by the Traction Company depends on the action of the City Council, and if that body reports favorably on the petitions of the Traction Company, operations are to be started immediately after the Carnival.

RICHMOND, VA.—Leading negro editors, physicians and ministers have formed a permanent organization here to boycott the street cars on account of the law recently passed allowing conductors to compel passengers to take such seats as they may designate. The negroes were advised to keep away from the theatres, which they must enter by a side entrance leading to a small gallery. The negro ministers are preaching sermons on the proposed boycott.

GUELPH, ONT.—The Street Railway Commissioners are considering the installation of a storage battery plant.

New Industrial Companies.

THE JONES FAN & MOTOR COMPANY has been incorporated in New York with a capital stock of $2,500. The directors are C. D. Marsh, L. A. Landau and James Jones, Jr., all of New York.

THE INDUSTRIAL TRANSPORTATION COMPANY has been incorporated at Washington, D. C., with a capital stock of $1,000,000. The incorporators are Edward Lugo-Vina, Edward D. N. Whitney, W. A. Copenhaver, Samuel H. Moore and E. L. Mattice.

THE AMERICAN SWITCH & SIGNAL COMPANY has been incorporated in Yuma, Ariz., for the purpose of building railroads, telegraph and telephone lines, electric railways and operating devices pertaining to switches. The capital stock is $1,000,000, and the incorporators are A. J. Gutzler, W. A. Bondurant, H. MacDavenport and others.

THE INDIANA & MICHIGAN ELECTRIC COMPANY has been incorporated in Jersey City, N. J., with a capital stock of $2,000,000. The incorporators are George W. Flaake, Jr., H. H. Porter, Francis Blossom, H. L. Cranford, Lyman L. Dyer Frederick V. Delafield, Frederick W. Longfellow, Henry S. Colwell and Harold S. Mackays.

THE AUTOMATIC MONITOR COMPANY has been incorporated at Toledo, Ohio, by Charles D. Miller, Morgan Levi, E. M. Taylor, H. R. Ashbrook, D. A. Yoder and S. Sanger. The company will manufacture a device to register the time consumed after the telephone receiver is lifted from the hook until the operator answers the call, and also record the time consumed in conversation over a long distance line.

Legal.

TELEPHONE WAR TAXES.—The United States Circuit Court of Appeals, sitting in New York City, has held that Spanish War taxes to the amount of $21,492, paid up on messages by the New York Telephone Company, are not to be refunded. The company sued Internal Revenue Collector Treat for the recovery of the money, on the ground that the fees for messages, at 15 cents each, according to the contracts with subscribers, were really based on the cost of maintaining wires and other expenses. It was held that the Government, in taxing messages, should not have levied its tax upon the full amount which the company collected from subscribers. The Court ruled that the company, by altering the phraseology of its contracts, might have escaped the tax but had not done so and was clearly liable.

LIGHTING AT DAVENPORT, IA.—An interesting case of some years standing has just been decided on appeal by the Supreme Court of Iowa. In 1896 the Davenport Gas & Electric Company made a contract with the city for 25 years which it proceeded to carry out until 1901, when it was ordered to install an alternating current system with alternating enclosed arcs in place of its direct current system. It did not do this, whereupon the city council nullified the contract franchise. The company has been sustained in its defense of its rights. The court says: "But, in addition to the finding of fact, which would alone determine the question in favor of plaintiff, we do not believe the ordinance contemplated such a change as was demanded. It will be remembered that the plaintiff installed a plant complying with the specification of the ordinance, and put in a large amount of new machinery at great expense, which the evidence shows would he rendered useless by the installation of the alternating system. The ordinance provides that at the commencement of each five-year period the city may require 'that all such machinery and appurtenances are in good condition and of such approved design as shall efficiently and properly produce gas and electric light of the required standard and power, and give the city and the citizens thereof the advantages of all improvements in the production of gas and electricity.' The machinery and appurtenances supplied under the required direction of the city were to be inspected, and required to be in good condition, and of such design as to furnish light of the 'standard and power' already designated, so that the city should have the advantage of all the improvements calculated to increase the efficiency of the system then in use. This construction is warranted from a consideration of the entire ordinance and in view of the fact that it is very improbable that either the city or the plaintiff contemplated that demands might be made at the beginning of each five-year period which would require an entire change of machinery and appurtenances, no matter how great the expense."

Personal.

M. FRANK TRUMBULL, of the Trumbull Electric Company, has gone on an extended trip to Cuba, Porta Rico and Mexico.

MR. C. H. HINES has severed his connection with the Canadian Pacific Railway Company as electrical engineer of the mechanical department, etc.

DR. CARY T. HUTCHINSON, consulting electrical engineer, has sailed for Europe, and will, it is said, spend two or three months on the other side.

MR. M. I. WILBERT, of the German Hospital, Philadelphia, is to lecture this week before the Franklin Institute on the phenomena of radioactivity and their applications, with illustrations.

MR. JOHN B. ALLAN, general manager of sales of the Allis-Chalmers Company, has resigned his position and expresses his intention of taking a vacation for a couple of months, in order to recuperate.

MR. J. T. P. KENYON has resigned from the engineering department of the New York Edison Company to become chief draughtsman of the electrical department of the New York Central & Hudson River Railroad.

MR. ANDREW CARNEGIE has created a $5,000,000 pension fund, the income of which is to be devoted to the relief from immediate suffering of the heroes in private life who sacrifice themselves in performing acts of courage to save others.

MR. C. C. GARRISON is now president of the Northern Engineering Company, Incorporated, White Building, Liberty Street, New York. Mr. C. Blake Garrison has been elected treasurer and Mr. B. R. Andrews has been appointed secretary of the concern.

MR. ARTHUR WEST, assistant chief engineer of the Allis-Chalmers Company, has resigned his position, and will go to the Mediterranean for a holiday trip. In his letter of resignation he says: "For the last couple of years I have been regularly overworked and my most urgent need is rest."

LIEUT. G. L. CARDEN, of the Department of Machinery, St. Louis World's Fair, lectured at Yale University on April 22, and the following evening in the auditorium of the new Y. M. C. A. building, New York, the subject being "Power Plant at St. Louis, and Some European Observations."

MR. SEYMOUR FOLWELL, at one time manager of the New York office of the British electrical engineering and contracting firm of Robert W. Blackwell & Company, Limited, and until recently connected with the sales department of the Cutter Company, of Philadelphia, is again on this side.

MR. WM. BARCLAY PARSONS, chief engineer of the New York Subway after an inspection of the Panama property, says the waterway can be successfully operated. Colon and Panama can be made healthful, he says, by sanitary precautions. He is a member of the U. S. Panama Canal Commission.

MR. WM. STANLEY, of Great Barrington, Mass., has recently taken a trip to Paris, France, in connection with some recent important work. The Pittsfield newspaper says that these new patents "propose to give the sun more vim and hang a new moon." We had thought that to be Mr. Tesla's special prerogative.

MR. A. M. MATTICE, chief engineer of the Allis-Chalmers Company has sailed for England this week on a brief business trip. He was accompanied by Mr. Fullagar, of the British turbine syndicate, who has been here for a few weeks, at Milwaukee, etc., in connection with Allis-Chalmers steam turbine development.

MR. FRANCIS BLOSSOM, of Sanderson & Porter, Kuhn-Loeb Building, New York, is expected back from New Orleans early next week where he went recently in connection with the New Orleans Railway Company's project to construct a new power plant to have an initial capacity of 7,000-hp and an ultimate development of 20,000-hp.

MR. WILLIAM N. SCOTT, manager of the Cutter Company of Philadelphia, has sailed for Europe for the purpose of closing some important contracts for circuit breakers, notably with the British Admiralty. The Cutter Company is represented in England by Robert W. Blackwell & Company, Limited. Mr. Scott expects to be abroad for about two months.

MR. JOHN I. BEGGS, president and general manager of the Milwaukee Electric Railway and Light Company, was presented by the officers and directors with a silver service in token of the esteem in which he is held by them at a banquet given for him on April 16. The silver is intended to form part of the equipment of a private car which is now being built for the use of Mr. Beggs.

MR. G. MARCONI.—Mr. Marconi, who has been interviewed by the *St. James's Gazette* on the question of his transatlantic "wireless" service says that his agreement with the Post Office which will be signed almost immediately, concedes all that his company has been asking for during the past few years. "As soon as the agreement has been signed," he added, "we shall start the service both to Canada and the United States."

MR. UGARTE, of the Mexican electrical engineering firm of Ugarte & Garcia, of Guadalajara, State of Jalisco, is now on his way to the States. His firm recently secured the contract for the construction of the electric lighting system in Colima, capital of the State of that name. Contracts have also been taken for the equipment of various hydraulic plants in the States of Jalisco and Coahuila, which will mean the purchase of considerable quantities of Yankee machinery, etc. Mr. Ugarte will visit St. Louis, Chicago, Pittsburg, and New York.

MR. C. A. MORENO, chief engineer of the St. Louis Transit Company, read a paper before the Engineers' Club of St. Louis, at its recent meeting, on the proposed method of handling visitors at the exposition. "The Transit Company, alone," he said, "will be able to take care of 50,000 passengers every hour. The Suburban Company has estimated its capacity of 10,000 per hour. The shuttle trains of the Wabash will accommodate 15,000 passengers per hour, making the total of 75,000. In fact, it would seem that the chief difficulty of the three Exposition lines will be—not how to take care of the people, but rather how to obtain enough passengers to take care of the new equipment that has been provided."

MR. ERVIN DRYER has resigned his position in connection with the Westinghouse Electric & Manufacturing Company, and has accepted an appointment with the Allis-Chalmers Company. Mr. Dryer's connection with the Westinghouse Company extended over a period of 16 years. He is one of the most competent salesmen in the electrical and mechanical field, and his wide acquaintance throughout the western part of the United States will be of great service to the Allis-Chalmers Company in the extensive new developments which they have undertaken. He has already entered upon his new duties with the Allis-Chalmers Company, and his headquarters will be at their offices in the New York Life Building, Chicago. He will give his attention to their engine work as well as to the sale of Bullock electrical apparatus, which the Allis-Chalmers Company now control through their acquisition of the Bullock Electrical Manufacturing Company, of Cincinnati.

DR. W. J. MORTON, the celebrated electro therapist of this city, has just sustained a deep personal bereavement in the death of his mother, Mrs. Elizabeth Morton, widow of Dr. W. T. G. Morton, discoverer of anesthesia, who died last week in this city at the Hotel Martha Washington, of pneumonia, following an illness of more than a year. Mrs. Morton, born in 1826, was married in 1844 to Dr. Morton, of Boston, Mass. A year of quiet married life had scarcely elapsed when her husband began that series of experiments upon lower animals, upon himself, and, finally, upon patients, which culminated in the great public demonstration that painless surgery by the inhalation of ether vapor was safe and practicable. No recognition of any sort from the American Government ever came to his widow, although the reports of six Congressional committees during her husband's lifetime had recommended an appropriation of several hundred thousand dollars be made in compensation for the Government's use of ether anesthesia during the civil war. A monument to his memory was erected on Boston Common, and other public tributes have since been made.

LORD KELVIN.—We quote the following from the *Manchester Guardian:* Lord Kelvin's election to the lord chancellorship of Glasgow University has loosened the flood of anecdotes which have gathered round his great name. I may be allowed to add two stories to that respectable record which have not, I think, seen print. Most Kelvin stories which obtain in Glasgow are founded upon the occasional inability of the great man who lisped in logarithms to bring his mind to a childish sum. The famous one tells how on his blackboard he once made two and two five, and, hearing the chuckles of his delighted class, altered it hastily to three. He was, however, once heard to say, in his characteristic slow way, with his beautiful use of the soft Irish r, "Seven times nine, Mr. Mac-far-lane, are a hundred and what? [Pause.] But, no: seven times nine cannot be a hundred and anything, Mr. Mac-far-lane, for the square of a hundred is ten." It is also told of him that, walking one day with a friend in Largs, he noticed that it had begun to rain. He questioned his friend closely as to where his coat and his umbrella were, and having satisfied himself that his friend had not these articles with him, he said: "Well, in that case, doctor, we will walk back beneath this belt of trees, for the rain will not per-colate the leaves, doctor, for twen-ty minutes."

MR. G. C. LLOYD.—Mr. George C. Lloyd has been appointed to the secretaryship of the British Institution of Electrical Engineers. Born in Lincolnshire in 1862, his father being the Rev. C. A. Lloyd, Rector of Rand, near Lincoln, Mr. Lloyd was educated partly in Germany, and on returning to England at the age of 17, he entered the works of Robert Stephenson & Co., locomotive and marine engine builders, Newcastle-upon-Tyne, as an apprentice. In 1884 he joined the firm of Messrs. Lamport and Holt, of Liverpool, in the capacity of marine engineer, and subsequently entered the service of the Spanish Royal Mail Steamship Co. (Compañia Transatlantica de Barcelona). He holds an extra first-class Board of Trade certificate. In the course of his voyages he visited the Philippine Islands five times, making a stay of one month on each occasion, and has also been in India, Brazil, the Argentine Republic and the West Indies, spending some three months in Cuba before the outbreak of the rebellion. He returned to England in 1891, and for the next nine years was engaged in engineering work in Glasgow and London. Since 1900, Mr. Lloyd has acted as chief assistant to the secretary of the Iron and Steel Institute. Mr. Lloyd is an excellent linguist. He enters on his duties on May 12th. Mr. Percy F. Rowell, chief assistant to the late Mr. McMillan, has been appointed assistant secretary.

NEW INSTITUTE MEMBERS.—At the April meeting of the Council of the American Institute of Electrical Engineers the following were elected to associate membership: Allen, Claxton Edmonds, assistant engineer General Electric Co., Lynn, Mass.; Appleton, Joseph, manager of construction, Electric Storage Battery Co., Philadelphia, Pa.; Berg, Edwin Victor, draughtsman, Telluride Power Co., Provo, Utah; Bott, George Robert, chief draughtsman, American Elevator Co., Columbus, Ohio; Boyd, Alexander A., general manager Michigan City Electric Co., Michigan City, Ind.; Bryant, Arthur Horace, tester Lamp Testing Bureau, New York City; Coggin, William Lord, tester General Electric Co., Lynn, Mass.; Cope, Albert Nathan, electrical engineer, Columbus Public Service Co., Columbus, Ohio; Costa, Louis J., manager, Jandus Electric Co., 1419 Real Estate Building, Philadelphia, Pa.; Crankshaw, J. B., resident engineer, Cincinnati Engineering and Investment Co., 1406 Traction Building, Cincinnati, Ohio; Crane, Charles Eugene, president and manager, Mutual Light & Heat Co., Seattle, Wash.; Davenport, Alfred La Rue, tester, Edison Electric Co. of Los Angeles, Long Beach, Cal.; Davis, Richmond Pearson, instructor, School of Submarine Defense, Fort Totten, N. Y.; Fenn, Ernest James, Steuart & Fenn, Dunedin, N. Z.; Fletcher, Raymond Fennimore, electrical engineer, McMaster and Fletcher, Columbus, Ohio; Griffin, Frank Albee, engineer, General Electric Co., Schenectady, N. Y.; Gillet, Louis Allston, assistant to secretary, American Society of Mechanical Engineers, New York City; Gresham, William Andrew, chief dynamo man, Georgia Electric Co., Atlanta, Ga.; Griffin, Thomas Lloyd, agent, General Electric Co., Wilkesbarre, Pa.; Hale, William Buell, laboratory chief, Western Electric Co., 259 S. Clinton St., Chicago, Ill.; Hedin, Kaleb, electrical engineer, Vesteras, Sweden; Hilbert, Alfred, draughtsman, S. M. Bixby, 1173 Fulton Ave., Bronx, New York City; Holland, Newman Henry, telephone engineer, Holtzer Cabot Electric Co., Wollaston, Mass.; Hulme, Frederick Wendell, electrical engineer, Hydro-electric Co., West End Hotel, St. Louis, Mo.; Johnston, D. McG., electrical engineer, The United Electric Co., Ltd., Toronto, Can.; Kaiser, Louis Theo., chief engineer, Thos. Emery's Sons, Hotel Emery, Cincinnati, Ohio; Kenyon, A. D., patent counsel, Kenyon and Kenyon, 49 Wall St., New York City; Kenyon, William Houston, patent lawyer, 49 Wall St., New York City; Lohman, Frank Henry, electrician, Calumet and Arizona Mining Co., Douglas, Ariz.; McBurney, Bruce Gordon, salesman, Canadian General Electric Co., Toronto, Ont.; McCall, Joseph B., president, The Philadelphia Electric Co., Philadelphia, Pa.; McMasters, James Clayton, McMasters and Fletcher, Columbus, Ohio; McNamee, Thomas Wilson, superintendent, Wabash Electric Light Co., Wabash, Ind.; Merrill, Meldon Humphrey, sales engineer, Westinghouse Electric and Mfg. Co., 716 Board of Trade Building, Boston, Mass.; Mettler, Hans Willi, draughtsman, Chicago Edison Co., Chicago, Ill.; Milch, Maurice, engineer, General Electric Co., Schenectady, N. Y.; Mitchell, Arthur Jesse, Southern representative, Adams Bagnall Electric Co., 323 Empire Building, Atlanta, Ga.; Mustard, John, manager, Wagner Electric Mfg. Co., 1617 Real Estate Trust Co., Philadelphia, Pa.; Newman, Mortimer Lewis, electrician, Dept. of Yards and Docks, Navy Yard, New York City; Nishikawa, Kikei, chief electrical engineer, Bessi Copper Mine, Iyo, Japan; Ovington, Earle Lewis, president, Ovington Mfg. Co., 4 Newcastle Court, Boston, Mass.; Phillips, Irving Wadsworth, student, General Electric Co., West Lynn, Mass.; Plaisted, Arthur I., engineering inspector, Metropolitan Water and Sewer Board, E. Somerville, Mass.; Reed, Frederick Holly, vice-president, J. G. White & Co., 43 Exchange Place, New York City; Richardson, Joseph W. A., contractor, 715 Union St., New Orleans, La.; Riggs, Walter Merritt, professor, Electrical Engineering, Clemson Agricultural College, Clemson College, S. C.; Salomon, Arthur F., manager, World's Fair Office, Nernst Lamp Co., St. Louis, Mo.; Schafer, Oliver Milton, superintendent, Fire Alarm and Police Telegraph, Trenton, N. J.; Shaw, Fred Menzies, tester, General Electric Co., Lynn, Mass.; Strohman, William, designer, Westinghouse Electric and Mfg. Co., Pittsburg, Pa.; Snyder, Henry Nicholas, superintendent, Santa Paula Electric Co., Santa Paula, Cal.; ter Meulen, F. W. von Lilienstern, assistant engineering, Westinghouse, Church, Kerr & Co., New York City; Tobey Jesse Orion, superintendent, Northern California Power Co., Manton, Cal.; Tomlinson, Harvey Strout, tester, General Electric Co., Lynn; res. Salem, Mass.; Tsukamoto, Chuzaburo, calculator, General Electric Co., Schenectady, N. Y.; Van Etten, Herbert Briant, assistant engineer, New York Telephone Co.; Vickers, Frederick Elwood, expert, General Electric Co., Los Angeles, Cal.; Wheeler, Burr, student, Columbia University, New York City; Wilgus, William John, fifth vice-president, New York Central and Hudson River R. R., New York City; Wilmerding, Charles Henry, consulting engineer, Room 1100, 84 Van Buren St., Chicago, Ill.; Yundt, George Jacob, electrical engineer, Southern Bell Telephone and Telegraph Co., Atlanta, Ga.; Zimmerman, Clarence Irving, assistant chemist, Nernst Lamp Co., Pittsburg, Pa.

Trade Notes.

BUFFALO FORGE COMPANY, of Buffalo, N. Y., has brought out a new eight-page, small size pamphlet devoted to its Buffalo hand blowers. Copies can be obtained on application.

THE FORT WAYNE ELECTRIC WORKS have opened a Pacific Coast branch office in San Francisco, Cal. Mr. F. V. T. Lee is manager of this office, which is located at 69-75 New Montgomery Street.

THE MACKAY ENGINEERING COMPANY, 149 Broadway, New York, announces that it has withdrawn from the arrangement whereby it represented the dynamos and motors of the Akron Electrical Mfg. Company.

YOST SOCKETS.—The Electrical Equipment & Supply Company, of 215½ Fourth Avenue, Pittsburg, Pa., has just assumed the representation of the Yost Electric Mfg. Company, for its socket specialties, etc., in Pittsburg and vicinity.

EMERSON ELEC. MFG. CO., St. Louis, Mo., has just issued a new bulletin as to its bi-polar direct current motors, ⅛ to ⅓-hp. These are of the enclosed cylindrical types TD62 and TD52 and are stout power motors with a heavy reserve, overload capacity. Two sizes of frames are used.

THE BROWN HOISTING MACHINERY COMPANY, of Cleveland, Ohio, has closed a contract for electric coal trimming machinery for the docks of the Hocking Valley Railway Company, at Toledo, Ohio. It is stated that this will be the first trimming coal machinery installed on the Lakes. It will effect a great saving in the handling of fuel.

THE BURT MANUFACTURING COMPANY, Akron, Ohio, manufacturer of the Cross oil filter, has just received an order from the Russian government for six oil filters, this being the tenth order from that government. These filters have acquired a reputation throughout Europe and the company is constantly making continental shipments.

GOULD STORAGE BATTERY COMPANY.—Mr. W. W. Donaldson, sales manager of the Gould Storage Battery Company, of 25 West 33d St., New York, announces that the company will move about May 1, and that on and after that date it will occupy the entire eighth floor of the New Century Building, 1 West 34th Street.

THE NEWMAN-WILLSON COMPANY, Lambertville, N. J., is manufacturing an oil filter which is claimed to save 50 per cent on an oil bill; saves 90 per cent of the oil, and, being automatic, requires little attention. Its merits will prove of interest to all having use for such a device. This company is composed of Messrs. W. S. Newman and E. L. Willson.

THE INTERNATIONAL TELEPHONE MANUFACTURING CO., Chicago, reports a constantly increasing demand for its long distance bridging toll line and country party line telephones for four-party selective signalling systems. The "International" bridging instrument is said to be, mechanically as well as electrically, one of the very best instruments of its kind.

THE UNITED TELPHERAGE COMPANY, 20 Broad Street, New York City, which has already done a large amount of heavy and light telpherage work with motor traveling on an aerial line, has now brought out an ingenious modification of its system for advertising purposes. The "ad" is suspended below the telpher, which travels up and down its track parallel to any railroad trolley line, highway, etc., thus attracting attention.

NILES-BEMENT-POND COMPANY, 136 Liberty Street, New York City, is issuing a neat "Progressive Reporter," illustrative and descriptive of its latest machine tools. The issue just received shows a 48-inch double planer, 60 inch double rotary planer hydraulic bar shear, hydraulic punching machine, horizontal milling machine, 68-inch slotting machine, new model turret lathe, 400-ton hydraulic wheel press, Corliss cylinder boring machine and motor driven horizontal machines.

THE ELECTRICAL TESTING LABORATORIES.—The fact should be generally known that the title of the corporation heretofore known as the Lamp Testing Bureau has been legally changed to be Electrical Testing Laboratories, and that the new corporation is in every respect the legal successor of the other, without change of officers or functions. The offices and laboratories have now been removed from No. 14 Jay Street to Eightieth Street and East End Avenue, New York.

WARNING.—We are advised by the General Electric Co. that a person calling himself Geo. E. McCante, and describing himself on his card as chief electrician of the General Electric Co., Schenectady, N. Y., is traveling in Texas and making representations that he is connected with the company. We are requested to state that there is no one of this name on the payroll of the General Electric Co. It is needless to add that no such person was ever its chief electrician.

BISSELL SIGN FLASHER.—The F. Bissell Company, of Toledo, O., reports that it is having a large sale of its new sign flasher for advertising purposes, etc. The regular design has 24 circuits, all or part of which may be used, while more circuits can be added. The contracts are made and broken by quick-break knife switches. The regular switch throws in lights one at a time until the entire sign is illuminated; but this effect can be varied. A catalogue will be sent on application.

LAMBERT SCHMIDT TELEPHONE MFG. COMPANY, of 85-93 Maple Street, Hoboken, N. J., has just issued catalogue No. 11 devoted to its well-known interior telephones. It is a handsome pamphlet of 24 pages and illustrates and describes its apparatus fully, all being intended to work primarily on the company's patented central energy circuit which requires but one bank of batteries, located at any convenient point. Only three more wires than telephones are necessary. A long list of users is also given.

CROCKER-WHEELER BRANCH IN NEW ORLEANS.—Crocker-Wheeler Company, manufacturers of electric generators and motors, will on May 10, open a branch office in the Hibernia Bank Building in New Orleans. Mr. W. P. Field, of the St. Louis office of the company, will be the representative in charge. Although there are 15 Crocker-Wheeler branches from Boston to San Francisco, including St. Louis and Atlanta, the establishment of this new office has become necessary in order to accommodate the steadily increasing market for electric machinery in the South and Southwest.

LAMP CONTRACTS.—"The contract method every time," says the Electric Appliance Company, Chicago, to people who are going to purchase lamps. "Whether a consumer's requirements call for one thousand, ten thousand or a hundred thousand lamps, he should buy them on contract and so be assured of the best price and best service." The company has just closed contracts with two of the largest consumers in the west for the Packard high-grade lamps and recommends all its customers to secure lamps on the contract basis.

THE WIRT ELECTRIC COMPANY is making arrangements to move into its new plant at the corner of Germantown Avenue and Pennsylvania Railroad tracks at North Philadelphia. It expects to get into its new building by May 1. This building gives it much more space than it at present has, and is arranged so that it has light on every side on every floor. The building is brick, of the modern mill construction. It may take the Wirt Electric Company a few days to get settled in its new shop, but it expects by May 7 to be running in its new quarters to its fullest capacity.

THE PUBLICATION DEPARTMENT of the B. F. Sturtevant Company is to receive generous recognition in the allotment of space in the new office building at Hyde Park, Mass. A portion of the high basement, about 40 ft. square, will be devoted to a press room and storage space for paper stock and printed matter. A full equipment of type and of jobbing and catalogue presses will be installed. Immediately above this room and occupying one end of the first story of the same building, will be the offices with a full complement of artists, clerks, etc. The Sturtevant Company has for several years maintained a printing plant of its own, and is to-day carrying through all the work required in connection with its publications except the engraving. This department will be one of the most extensive and progressive connected with any manufacturing concern of its character in the country.

LOW-SERVICE COMPRESSORS FOR AIR AND CARBONIC-ACID GAS. A 12-page pamphlet, published by the Laidlaw-Dunn-Gordon Company, of 114 Liberty St., New York City, describes compressors intended for pressures of 30 lbs. and under. These compressors are built with open suction for supplying air at low pressure, or with closed suction for handling carbonic acid and other gasses. The inlet valves are of the semi-rotary type, while the outlet valves are of the poppet type. Rotary valves are considered superior for inlet service, not only because of their greater efficiency and durability, but furthermore because they open promptly and offer no resistance to the incoming air, which the poppet valve held down by a spring must necessarily do, thus cutting down the volume capacity of the compressor. The discharge valves, on the other hand, present a different problem, owing to the fact that the point of opening should vary with variations in pressure, and the poppet type has been adopted for this service.

"BIAS LINOTAPE."—The Mica Insulator Company, of New York and Chicago, is now placing on the market an entirely new product under the trade name "Bias Linotape." This material is, as its name suggests, a tape cut on the true bias and coated with a film of its Empire oxidized linseed oil. It is extremely flexible and can be wrapped around sharp corners and turns where straight tape cannot be used. It is designed especially for use in insulating armatures, field magnet coils, cables, switchboards and high tension work, as well as in other places where a high grade of electrical and mechanical insulating tape is required. The manufacturer is distributing small samples of this tape and announces its willingness to mail the same upon application. It filled some very large orders for the goods recently, and the trade seem to be very enthusiastic regarding them. This company reports increased sales in its standard lines of micanite, Empire and M. I. C. compound materials which it originated and brought out ten years ago.

BRISTOL EXHIBIT AT ST. LOUIS.—The Bristol Company, of Waterbury, Conn., is sending an exhibit to St. Louis which will be placed in Electricity Building, in space 36, near the main entrance. The company will show a complete line of its recording instruments for pressure, temperature and electricity. These instruments will be shown in various styles and sizes and in different finishes. The construction and operative parts will also be shown and a large number of the instruments will be in actual operation, enabling visitors to observe the manner of operation and the records the instruments make, also the extreme simplicity of the different instruments and the delicacy and accuracy which it is possible to obtain without sacrificing any of the necessary elements which are essential in a commercial form of a recording instrument. There will also be shown a complete line of specimens of Bristol patent steel belt lacing which comprises over 150 different sizes for all kinds of belting from the thinnest to the heaviest that is made, such as is used for conveying belts.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED APRIL 19, 1904.

[Conducted by Wm. A. Rosenbaum, Patent Attorney, 140 Nassau St., N. Y.]

757,557. ELECTROLYTIC DEPOSITION APPARATUS; William J. Joly O. App. filed June 18, 1903. Where the terminals of main wires are to be moved from time to time to follow the movements of a machine supplied through branch wires from the mains, the mains terminate in coils wound upon spools, which are supported upon a portable bracket; as the bracket is moved about the reels give off the main wires.

757,441. CLUSTER SOCKET; John H. Dale, New York, N. Y. App. filed Feb. 18, 1904. The finishing cap containing the openings for the lamp bases, supports inside, a block of insulating material to which all of the lamp terminals are attached, and by removing the cap from its support, the two binding posts for the line wires are exposed.

757,495. ELECTRIC SOLE SHOE; Adam Reed, St. Joseph, Mo. App. filed Feb. 4, 1904. Copper and zinc plates are arranged in a porous insole.

757,503. TELEGRAPH SYSTEM; Harry O. Rugh, Chicago, Ill. App. filed Aug. 31, 1903. This patent and those following in the same name provide a system and apparatus whereby wave-form current, as alternating current of suitably high frequency, may be employed in effecting telegraphic signals. The same circuit may be employed simultaneously for both direct and wave-form currents.

757,504. TELEGRAPHIC SYSTEM; Harry O. Rugh, Chicago, Ill. App. filed Aug. 21, 1903. See No. 757,503.

757,505. TELEGRAPHY Harry O. Rugh, Chicago, Ill. App. filed Aug. 31, 1903. See patent 757,503.

757,515. PHASE REGULATION; Egbert M. Tingley, Wilkinsburg, Pa. App. filed May 9, 1896. This patent and those following in the same name provide for securing a desired phase angle between the shunt and series fields when there is no current lag in the work circuit by displacing the current in one of the field coils with reference to that in the other or in both of said coils.

757,516. PHASE ANGLE ADJUSTING MEANS; Egbert M. Tingley, Pittsburg, Pa. App. filed April 24, 1900. See preceding patent.

757,517. METHOD OF PHASE ANGLE ADJUSTMENT; Egbert M. Tingley, Pittsburg, Pa. App. filed April 24, 1900. See patent 757,515.

757,518. METHOD OF PHASE ANGLE ADJUSTMENT; Egbert M. Tingley, Pittsburg, Pa. App. filed Feb. 4, 1901. See patent 757,515.

757,523. INDUCTION COIL; Richard Varley, Providence, R. I. App. filed Dec. 14, 1903. The sectional secondary winding is placed as usual axially over the primary winding and core and is inclosed in a porcelain cylinder having an inwardly projecting flange which enters between the sections of the secondary winding, the latter being so wound that the sections are connected together at the inner layers, so that the points of greatest difference of potential will be separated by the partition

757,524. INDUCTION COIL; Richard Varley, Providence, R. I. App. filed Dec. 30, 1903. A porcelain or glass cup passes over one end of the primary winding and core and is itself surrounded by one section of the secondary winding, the other section being placed around the uncovered portion of the primary and core, the whole being inclosed in a porcelain cylinder or cup.

757,525. INDUCTION COIL; Richard Varley, Providence, R. I. App. filed Jan. 12, 1904. A number of Ruhmkorff coils are placed in a single box and their armatures arranged to act upon a vibrator common to all of them.

757,527. VIBRATOR FOR INDUCTION COILS; Richard Varley, Providence, R. I. App. filed Jan. 20, 1904. The contact screw of the vibrator is arranged to be tipped so that its platinum point can be exposed for inspection and cleaning whenever necessary.

757,537. METHOD OF SIGNALING FOR ELECTRIC RAILWAYS; Samuel M. Young, New York, N. Y. App. filed Nov. 6, 1903. Consists in creating a difference of potential between the traffic rails of the system which separately form return paths for the power circuit and over which a current differing in character is flowing, actuating signal devices by the current due to such difference of potential and shunting said current around certain of the signalling devices by the aid of apparatus actuated by the power current.

757,541. PUSH BUTTON SWITCH; Walter A. Church, Binghamton, N. Y. App. filed June 17, 1903. Details.

757,557. ELECTROLYTIC DEPOSITION APPARATUS; William J. Joly and Joseph H. Joly, San Francisco, Cal. App. filed April 7, 1903. (See page 821.)

757,559. WIRELESS TELEGRAPH SYSTEM; Guglielmo Marconi, London, England. App. filed Nov. 19, 1901. At a station employed in wireless telegraphy, a conductor, a number of open circuits electrically connected with the conductor, a corresponding number of instruments, one electrically connected with each open circuit and means whereby the time periods of the open circuit are caused to differ from each other.

757,564. ELECTRIC HEADLIGHT; William H. Northall, Elwood, Ind. App. filed March 20, 1903. The lamp can be "turned down" by adjusting the length of the arc between the carbons.

757,609. ELECTRICAL TELEPHONE APPARATUS; Pliny H. Fisk, Clay, Ia. App. filed June 13, 1903. (See page 822.)

757,617. PROCESS OF PRODUCING CARBIDE; William Smith Horry, Niagara Falls, N. Y. App. filed March 29, 1902. (See page 821.)

757,618. PROCESS OF ELECTRIC HEATING; William Smith Horry, Niagara Falls, N. Y. App. filed April 5, 1902. (See page 821.)

757,619. PROCESS OF ELECTRIC HEATING; William Smith Horry, Niagara Falls, N. Y. App. filed April 28, 1902. (See page 821.)

757,620. METHOD OF ELECTRIC HEATING; William Smith Horry, Niagara Falls, N. Y. App. filed June 6, 1902. (See page 821.)

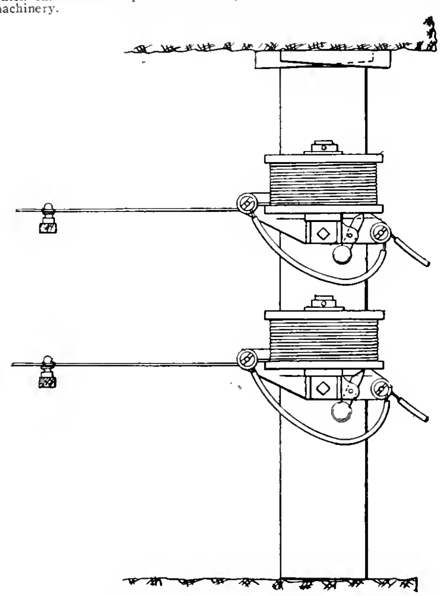
757,621. ELECTRIC FURNACE; William Smith Horry and Edgar F. Price, Niagara Falls, N. Y. App. filed Oct. 11, 1902. (See page 821.)

757,630. SAFETY DEVICE FOR TROLLEY POLES; Phelam McCullough, Thomas Planey and Robert Baron, Liverpool, Eng. App. filed Jan. 22, 1901. Details of a trolley retriever.

757,633. ELECTRIC HEATING; Edgar F. Price, Niagara Falls, N. Y. App. filed April 30, 1903. (See page 821.)

757,634. ELECTRIC RESISTANCE FURNACE; Edgar F. Price, Niagara Falls, N. Y. App. filed April 30, 1903. (See page 821.)

757,636. FLY WHEEL FOR QUICK-RUNNING INTERNAL COMBUSTION ENGINES; Firtz Reichenbach, Charlottenburg, Germany. App. filed June 19, 1903. The fly-wheel is combined with the field magnet of the inductor which furnishes the sparks in the engine cylinder, to reduce weight of the machinery.



756,850.—Electrical Wire Station.

757,637. GAS BATTERY; James H. Reid, Newark, N. J. App. filed Aug. 3, 1903. (See page 821.)

757,659. ELECTRIC ARC LAMP; Robert Hopfelt, Berlin, Germany. App. filed May 13, 1902. The negative carbon is placed above and the positive below, and the electrodes contain certain proportions of metal for lessening the formation of slag.

757,670. ELECTRICALLY HEATER SOLDERING IRON; Alfred C. McCloskey, Philadelphia, Pa. App. filed May 6, 1903. Details.

757,687. RHEOSTAT; Imle E. Storey, Amsterdam, N. Y. App. filed Sept. 2, 1903. A plurality of tubular resistance elements, metallic end-pieces connecting them together in series and insulated rods extending through the tube and in contact alternately with end pieces at opposite ends of the tube, whereby connections are made from one side only of the rheostat.

757,692. BLOCK SYSTEM EMERGENCY APPARATUS; Frederick V. Thomson, Philadelphia, Pa. App. filed Jan. 10, 1903. Details.

757,695. ELECTRIC LIGHTING AND POWER SYSTEM; William A. Turnbayne, Buffalo, N. Y. App. filed Sept. 29, 1903. An electric motor driving an exciter for a generator driven from a car axle, is so connected up as to ensure a constant e.m.f. at the terminals of the generator.

757,715. PROPULSION OF ELECTRIC AUTOMOBILES; Jonas W. Aylsworth, East Orange, N. J. App. filed June 24, 1903. Both the field and armature are rotative and can be geared to the driving wheels as desired to maintain a uniform relative speed of the parts, notwithstanding changes in the load.

757,782. ELECTRIC ARC RUPTURING DEVICE; Sidney H. Short, London, Eng. App. filed Feb. 11, 1902. The contact points between which the arc is likely to be formed are placed between the bare poles of an electromagnet, the pole-pieces being insulated from the magnet core, so that the arc in deflecting will not find a path through the magnet core.

757,785. SPRING JACK FOR TELEGRAPH SWITCHBOARDS; John F. Skirrow, East Orange, N. J. App. filed Dec. 16, 1903. The jack is adapted to receive an identification card.

757,786. TROLLEY; Cyrus E. Smith, Fall River, Mass. App. filed Sept. 25, 1903. Details.

757,789. ELEVATOR BRAKE MECHANISM; August Sundh, Yonkers, N. Y. App. filed Aug. 5, 1903. A compound brake mechanism whereby the rotary force of the motor becomes directly applied to the hoisting drums through the previous setting of primary brakes upon a friction disk carried by the rotary motor armature shaft.

757,792. CIRCUIT CONTROLLER FOR INDUCTION COILS; Richard Varley, Providence, R. I. App. filed Jan. 20, 1904. There are two sets of platinum contacts for the vibrator, one of which may be thrown into service when the other becomes defective.

757,799. TELEPHONE TRANSMITTER; Walter L. Wilhelm, Buffalo, N. Y. App. filed Jan. 23, 1902. (See page 822.)

757,802. WAVE RESPONSIVE DEVICE; Albert E. Woodward, Nashua, N. H. App. filed July 9, 1903. The device comprises an aluminum disk in contact on each side with two polished steel balls, all held together by pressure.

757,809. BINDING POST; Stephen C. Houghton, San Francisco, Cal. App. filed Dec. 30, 1903. A pointed screw clamps the wire against an inclined surface.

757,817. PROCESS OF ELECTROLYTICALLY EXTRACTING COPPER AND ZINC FROM ORES; Stanislaw Laszczynski, Kielce, Russia. App. filed Oct. 10, 1902. (See page 821.)

757,824. TROLLEY BASE; Frederick S. Martin, Pittsburg, Pa. App. filed Sept. 4, 1903. A ring-shaped trolley base having a ball bearing upon a ring-shaped platform.

757,826. TELEPHONY; Albert Meinema, Chicago, Ill. App. filed Jan. 16, 1904. (See page 822.)

757,830. MEANS FOR PROTECTING LIVE PARTS OF ELECTRIC SWITCHES OR THE LIKE; William McDevitt, Philadelphia, Pa. App. filed Sept. 26, 1903. The metallic parts are sunken in grooves and cavities in the base.

757,847. ELECTRIC ARC LAMP; Frederik Sindingchristensen, New York, N. Y. App. filed May 4, 1903. Two armatures actuated by a single magnet and respectively controlling the arc-forming and the feeding mechanism.

757,850. ANTISEPTIC ATTACHMENT FOR TELEPHONES; Hugh L. Thompson. App. filed March 1, 1904. (See page 822.)

757,853. ELECTRIC SWITCH; George H. Whittingham, New York, N. Y. App. filed Oct. 29, 1903. The switch comprises opening and closing devices for supply and armature circuits, that for the supply circuit including a blow-out device, a second blow-out device designed to be included in a brake resistance circuit and means for actuating the blow-out devices alternately.

757,880. ELECTRIC RHEOSTAT; Roy W. Brown, Amsterdam, N. Y. App. filed April 21, 1903. Details.

757,884. THERMAL CUT OUT; Henry P. Clausen, Chicago, Ill. App. filed July 18, 1903. A thin sheet of solder separates two sharp edged members which have a shearing action as soon as the solder becomes slightly softened.

757,898. ELECTRIC CONTROLLER; Arthur C. Eastwood, Cleveland, Ohio. App. filed Jan. 30, 1904. Details.

757,906. ELECTRIC RAILWAY; George H. Fretts, Springfield, Mass. App. filed July 14, 1903. A switch point in the trolley wire can be moved at will by the motorman operating certain electric switches.

757,925. ELECTRIC SWITCH; Charles F. Hopewell, Cambridge, Mass. App. filed Oct. 7, 1903. Details of a tappet switch for trolley wires.

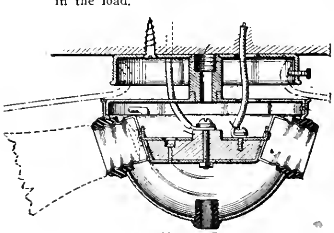
757,942. AUTOMATIC COMMUTATOR; Julien Henri Mercadier, Louvres, France. App. filed Oct. 16, 1903. Details.

757,943. STORAGE BATTERY; Abraham V. Meserole, New York, N. Y. App. filed July 13, 1903. (See page 821.)

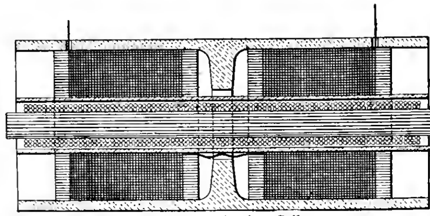
757,958. ELECTRIC ARC LAMP; Isaac W. Percival, St. Louis, Mo. App. filed Jan. 23, 1899. Two sets of carbons placed in one lamp and each designed to take 110 volts in series on a 220-volt circuit.

757,971. THERMAL CUT OUT; Michael Setter, Chicago, Ill. App. filed Aug. 5, 1903. Two telescoping members are held normally apart by a body of solder.

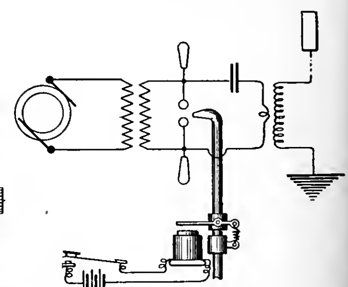
757,972. THERMAL CUT OUT; Michael Setter, Chicago, Ill. App. filed Aug. 5, 1903. Two members normally pulled apart by a spring are held together by solder.



757,441.—Cluster Socket.



757,523.—Induction Coil.



758,005.—Apparatus Employed in Wireless Telegraphy.

757,718. PROCESS OF MAKING STORAGE BATTERY PLATES; Joseph Bijur, New York, N. Y. App. filed Feb. 10, 1903. (See page 821.)

757,722. ELECTRIC SEMAPHORE; Dona Boisvert, Providence, R. I. App. filed Oct. 13, 1902. Details.

757,736. MULTIPLEX TELEGRAPHY; John J. Ghegan, Newark, N. J. App. filed July 3, 1902. A main line, two sets of transmitters and receivers at a number of stations, and means operated by the main line current for switching the corresponding sides of said sets alternately into and out of the main line.

757,765. INSULATOR; John W. Osborne, Winchester, Ill. App. filed Aug. 15, 1903. Details.

757,768. SIGNAL APPARATUS; Jonathan D. Price, Aurora, Ill. App. filed Jan. 21, 1902. Details of the mechanism and apparatus in a railway block signal system.

757,991. RECIPROCATING ELECTRIC MOTOR; Adolph F. Christmas, Pittsburg, Pa. App. filed March 16, 1903. Details of a circuit changer.

758,004. DEVICE FOR WIRELESS TELEGRAPHY; John Ambrose Fleming, London, Eng. App. filed April 8, 1901. The signal key is used to vary the current in the primary which is otherwise continuous, the signals being thus effected.

758,005. APPARATUS EMPLOYED IN WIRELESS TELEGRAPHY; John Ambrose Fleming, London, Eng. App. filed Nov. 9, 1901. A constant stream of sparks across the terminals are broken up into signals by intermittent blasts of air.

758,006. WIRELESS TELEGRAPHY; Francis J. Green, Detroit, Mich. App. filed Jan. 9, 1903. An application of wireless telegraphy to railway signaling.

758,031. TELEPHONE DESK SET; Henry P. Clausen, Chicago, Ill. App. filed May 26, 1902. (See page 821.)

Electrical World and Engineer

CONTENTS.

SIXTY YEARS OF THE TELEGRAPH.

The past week has witnessed the sixtieth anniversary of the electromagnetic telegraph, it being May 1, 1844, when Prof. Morse was able to demonstrate the use of his invention in reporting at Washington the proceedings of the Whig Convention at Baltimore. Since that time the history of the telegraph in this country and elsewhere has been one of steady advance and of universal benefit. It is certainly a moot question whether of late years the telegraph has advanced as rapidly as it might have done, and whether it has not become more or less crystallized and fossilized in its apparatus and methods. Yet even this statement must be made guardedly, for while the great telegraph systems the world over appear to look askance on automatic and machine methods, the wireless telegraph inventions have been generally taken up and pushed with great success; and if there is anything more wonderful and stimulating in the domain of electrical advance at the present time than the wireless we do not know what it is.

The amount of service rendered to the public by the telegraph sixty years after its practical inception may be gauged from the fact that in only four or five of the leading countries, 400,000,000 or 500,000,000 authentic messages are dispatched annually exclusive of those handled by leased private wires. In this country the record is now probably about 100,000,000 a year, while Great Britain does not fall very far behind that. Germany and France together are good for another 100,000,000, while Russia, Italy, Austria and Spain will probably account for another batch of equal magnitude. The telephone to-day has asserted for itself the function of knitting closely together the various communities in which it is used, but it is still the proud boast of the telegraph and the submarine cable that they have been the great instrumentality in annihilating distance, promoting intercourse and commerce and bringing the nations together.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION

We are very glad to be able to present on another page the programme of the National Electric Light Convention, to be held in Boston at the end of this month. President Edgar and the officials are to be congratulated upon the excellent list of papers they have secured. In fact, it is a matter for wonder how they expect to get through it in the brief time available, for so far as we can judge, it far exceeds anything the Association has attempted for years past. The programme of entertainment is also very alluring, and there is no question as to the warmth of the welcome which awaits the electric lighting fraternity at Boston this month.

It is rather remarkable that the Electric Light Convention has not been held in Boston since 1887. A great deal of water has run under the bridge since then, and it was certainly high time that the Association visited again a city of so many attractions—from whatever standpoint it be regarded. The early Brush arc lighting work done there by the late Mr. Gilbert will not soon be forgotten; the fact that Boston was so long the headquarters of the Thomson-Houston Company gave it special importance for many years, while of late the aggressive and intelligent work of Mr. Edgar has made the city the center of remarkably rapid development and improvement in the applications of electric light and power. Altogether a better choice of convention city could not have been made, and we venture to believe that the convention will be one of the largest and best that the Association has ever conducted.

Large Electrical Manufacture.

We publish elsewhere in this issue a synopsis of the annual report of the General Electric Company just issued. It is naturally a most interesting document, and in its fullness of detail may well be commended as an example of the kind of statement to which the public is entitled respecting the affairs of industrial corporations whose stocks are quoted on the exchange. The General Electric Company, in spite of the slackness and dullness of last year, enjoyed wonderful prosperity, with gross receipts reaching nearly $43,000,000, or more than $4,500,000 above those of last year. At the same time the net earnings were by no means so high, amounting after payment of interest on debentures to $7,789,300, against $10,232,800 in the preceding year. There were various reasons for this, but it may be noted also that the amount of orders billed was also nearly $900,000 less. The company in the last ten years has written off nearly $12,000,000 on its factories and carries them now at $6,500,000, which is extremely conservative. As a matter of fact, the company would appear to be doing about 25 per cent. of the entire electrical manufacturing of the country, and of course a very much larger percentage of that which falls within its own special fields. Moreover, the net profits of the year before writing off depreciation were equal to over 22 per cent. on the stock and 18 per cent. after charging off depreciation. Many of the details given in our synopsis, as well as in the full document, are of great interest and suggestiveness, particularly the items with regard to power transmission, the development of the multiple-unit system, the introduction of the steam turbine and the equipment of steam railroads with electricity. Some idea of the expansion of the company's business may be inferred from the fact that as recently as 1901 the gross receipts were below $30,000,000. Within the three years they are nearly half as much again.

Our Patent System.

We are glad to publish the important suggestions of ex-Commissioner of Patents Seymour on reform in our present system. In justice to ourselves, however, we must correct some apparent misconceptions. In the first place, we have, and have freely expressed, a very bad opinion of "working" as customarily practiced. It is a solemn farce in most cases and does not serve to protect the public. The plan which we have advocated is a very different process of elimination. It practically makes the original issue for a short term subject to extension for suitable cause. The patentee at the end of, say, six or seven years, would have to come forward and show either that the invention was being so manufactured as to meet public demand fully and squarely, or in default of such working that there was complete and adequate cause for the default. In the hypothetical case of a patented torpedo boat cited by Mr. Seymour, the inventor would have to show that he had diligently and in good faith prosecuted the invention, endeavoring to procure its adoption and manufacture. If it had been steadily turned down by all those who had investigated it, it would be safe to conclude that it did not possess such merit as would warrant an extension. There are many inventions which require large expenditure for reduction to practice, and in all such cases the inventor should have the benefit of the doubt, but such cases form a very small proportion of the total of unused patents. Most of these are either without merit in a commercial sense or are obstructive patents held by the owners, generally large corporations to prevent competition at the hands of rivals. All these ought in the public interest to be extinguished once for all.

We are well aware of the provisions of the law in the case of prior publication whether in an expired patent or elsewhere, but there is a vast difference between falling afoul of these and infringing a patent in being. The latter, whether of public use or not, holds all improvements tributary and hence discourages them, while the former only serve to obstruct broad claims. Every large corporation holds patents which it does not use nor intend to use, but which serve to prohibit improvements along similar lines. As a matter of justice to the public, the whole crew of useless or shelved patents ought to be put out of the way, and we know of no more effective way of doing it than by requiring the owners to show just cause for an extension of term. Mr. Seymour's comments on the compulsory licenses are to the point, but they do not go in our judgment quite far enough, since they compel the public to pay tribute for a right which the owner does not himself deign to use. The poor inventor does not need to be clubbed into giving a license. If compulsory license is needed anywhere, it is in behalf of improvements blocked by earlier patents, used or unused. We heartily agree with Mr. Seymour in the necessity for more care in the Patent Office searches with respect to novelty, and in his appreciation of the need for greater liberality in the case of broad inventions, hitherto only patentable in detached segments sometimes very hard to protect singly. In fact, we think the office overhauling of applications should be so thorough as to bar lack of invention as a defense in infringement cases, and to make anticipation very difficult to establish. But the public needs protection against the use of patents to obstruct improvements. There is a deal of Buncombe over justice to the struggling inventor, for that needy person has generally sold his birthright for a mess of pottage long before the invention has come into common use; and a show-down of ownership in patents of actual or potential importance would disclose most of them in the hands of sleek promoters or of corporations using them to minimize competition from improvements. This is commercially legitimate, but it is far from the primary purpose of a patent system.

Municipal Improvement Loans.

We note that several of the English financial authorities are calling attention to the grave position of municipal credit in the British Isles and expressing concern over the heavy strain that principal corporations are undergoing in their efforts to meet the enormous liabilities imposed upon them by the various trading operations upon which so many of them have launched. The London *Argus* enumerates some instances of the kind, and mentions the fact, as an example, that all the Birkenhead loans are at a discount. Glasgow, which runs everything for itself, including the cradle and the grave, is offering a half per cent. over the deposit rate of the Scotch banks on loans for a month. In no fewer than 18 large municipalities the 3 per cent. loans that eight years ago were at a premium are now at a discount, and appeals are being made right and left for loans even in small sums, predicated on mortgages of corporation revenues. In London, where all kinds of enterprises have been indulged in, some electrical, a halt has been called, and none too soon. It is bad enough to have a score or two of nations load themselves with debt in order to destroy each other's savings by bloody warfare. It is worse to have hundreds of municipalities plunging headlong into crazy financing and obligation, the sole object of which is to check and choke the enterprise and thrift of their own citizens. There is as little excuse for the one form of borrowing as for the other.

The indebtedness of local authorities in the United Kingdom has nearly doubled in ten years, and in 1902 was already $2,000,000,000.

Terrific as these figures appear, we can match them in the United States, although the sturdy individualism of our people has not yet yielded so fully as that of the European to the rule of others mightier than ourselves which makes for bankruptcy. We have lots of cities with a debt of over $10,000,000. Boston and Philadelphia have both over $50,000,000. Chicago has but $15,000,000, yet is always hard up. St. Louis has nearly $25,000,000. But these figures are child's play alongside the returns from Gotham. The budget for 1902 for Greater New York City provided over $23,000,000 for interest and redemption of city debt, and since then it has been piled up higher and higher. Some enthusiastic New York socialists would like to throw away several hundred millions more even now on lighting plants and trolley lines; but there is a limit, and there will soon be a sharp jolt and halt. The *World's Work* points out that the city budget is bigger than that of any five other cities in the country; that the city employs 46,000 persons, and that it pays wages and salaries amounting to $55,000,000 a year, at the highest rates known in the vicinity. Well may the magazine we quote say: "No company or private business could afford such a drain upon its resources." We are no alarmists. The strong, healthy optimism of American growth is ours, but we do not hesitate to say that such exhibitions of the unmitigated tendency to have the municipality do everything, and to put every citizen in buttons is both dangerous and disgraceful to our nation.

American Industries and the Metric System.

The National Association of Manufacturers has recently published in a supplement to *American Industries*, for April 15, 1904, a detailed analysis of replies elicited by a circular letter addressed at the end of last year to about 2,800 members of the Association, on the subject of the metric system bill. The tone of the circular letter shows that the circular letter was devised in a spirit of antagonism to the metric system, and that its purpose was to elicit as far as possible the hostile sentiments of the Association members towards the metric system bill, which, as drafted in 1903, contemplated compulsory adoption of the system by the United States at large. Consequently, while there is no reason to suppose that the Association management has in any way misrepresented the returns to the letter, it seems probable that the tone and purpose of the letter have elicited the greatest hostility that the bill can evoke from the membership, and that if a circular letter had been drawn up in the opposite spirit of eliciting as far as possible the favorable spirit of the membership towards the adoption of the metric system in some manner, as distinguished from compulsory adoption at the date of January 1, 1907, a much more favorable set of returns for the metric system might have been looked for. Nevertheless, the results published are very encouraging, and we owe our thanks to the National Association of Manufacturers for their pains in issuing the letter and in tabulating the published returns.

It seems that 774 replies were returned, or from about 36 per cent. of the members addressed. Eleven questions were asked in the letter. There is no fault to find with these questions, considered independently of the letter accompanying them. We need only consider the last question, which was: "Should the metric system be made the legal standard of the country?" There are 707 recorded answers tabulated for this question, and 141 were affirmative, 87 were noncommittal, and 479 negative. This means that 20 per cent. of the answers as tabulated were in favor of the metric system as a legal standard, and 67.7 per cent. were against the metric system. Broadly speaking, therefore, two-thirds of those who voted, voted against the metric system, while one-fifth voted for it. The percentage in favor of the metric system as a legal standard in the tabulated return is 25.5 per cent. in the metal group and 15 per cent. in the non-metal group of manufacturers. It reaches a maximum of 32 per cent. among manufacturers of electric machinery, and is lowest in boots (4.5 per cent.). The boot industry is clearly wedded to the English foot. So far as the favor of the metric system in industry is concerned, it seems that electricity is at the head of the procession.

Altogether, the result is very encouraging and satisfactory, from the standpoint of international unity of weights and measures. Ten years ago had such a ballot been taken, the returns in favor of the metric system would probably have been only about 5 per cent., and evidences are abundant that the metric system makes steady progress towards favor. Three engineering societies are down as favoring the bill; namely, the Boston Society of Civil Engineers, the Engineers' Society of Western Pennsylvania and the Western Society of Engineers. We know at least three more among the most prominent in the country that might have been included in the list if they had been consulted, their pro-metric votes having been officially published. Seven engineering societies are tabulated as against the measure. Among commercial associations, 9 are down as in favor of the bill, and 14 against it. Among manufacturers' associations, 2 for and 21 against. If the same incompleteness of returns exists in the two latter classes as we know to exist in the first class,, material changes in these numbers might also be looked for. But the result of any canvass of the metric system among manufacturers is necessarily a limited criterion of the value of the system to the country at large, and even of its ultimate value to the manufacturers themselves. In these days of keen competition, a profitable business implies a skillful adjustment with respect to numerous factors, and a favorable balance sheet is the question of the hour, not of the distant future. Opportunism is thus almost necessarily the guiding policy in manufacturing, and even though personally recognizing the intrinsic merits of the metric system, a manufacturer as such is apt to view its adoption only in the light of involving an expense without prospect of any immediate return, and as menacing a delicately balanced factory organization.

Electrical Methods of Determining Torque.

There are various well-known methods of measuring torque mechanically. For example, a pair of pulleys set independently side by side and connected by a spring or springs, enable the torque communicated from one to the other to be measured, during rotation, by the distortion of the springs. Every mechanical transmission dynamometer is, in fact, a torque measurer. The electric motor is generally considered as the most convenient and reliable transmission dynamometer, since the power transmitted is capable of being readily measured in watts, and this power, divided by the angular velocity of the motor shaft, in radians per second, gives the torque at once in dyne-centimeters, and thus, by conversion, in pounds-feet or other desired unit. The method is very convenient, and its accuracy is limited only by the accuracy of the wattmeter and of the speed measurer. Prof. McAllister's article on page 871 refers to a refinement in the method of torque measurement by the use of the shunt electric motor. The refinement consists in the elimination of the extra torque to the conditions of measurement, such as that due to the belt connection between the machine to be tested and the shunt machine, which gives the measurement. The shunt machine first drives both machines, taking from its mains the power required to overcome the frictions of both. Next the machine to be tested takes power from its mains and assumes a share of the load, the amount of its load being adjustable. The change in the current of the shunt machine measures the mechanical torque exerted by the tested machine. That is to say, the formula yields the torque which the tested machine gives to its shaft and bearings, after paying for internal electrical and mechanical frictions.

Programme of the National Electric Light Convention.

The following is the programme of papers and reports to be presented at the twenty-seventh convention of the National Electric Light Association, to be held in Boston May 24, 25, 26 and 27:

"The Sale of Electrical Energy," W. F. White; "Economy Test of a 5,500-hp, Three-Cylinder Compound Engine and Generator," J. D. Andrew and W. F. Wells; "A One-Hundred-Mile Transmission Line," Robert Howes; "The Mechanical Stoker and the Human Operator," Edwin Yawger; "The Organization and Equipment of an Arc Lamp Department," Samuel G. Rhodes; "Practical Notes on Steam Turbines," Francis Hodgkinson; "Electric Light and Power Plants in Connection with Ice Plants," C. L. Wakefield; "Single-Phase Power Motors for Electric Lighting Stations," W. A. Layman; "A Three-Wire, 500-Volt Lighting System," Walter I. Barnes; "Notes on the Internal Combustion Engine as Applied to Central Station Service," E. E. Arnold; "A Proposed System of Standard Instruments for Operating Companies," H. P. Davis; "Remote Control of Electrical Apparatus," William H. Cole.

In addition to these papers, which are already in print, are three or four others on timely subjects which have not yet gone to press, among them one by Dr. F. A. C. Perrine, on "Types of Large Water Power Installations." The reports are as follows: Report on Progress, T. Commerford Martin; report of Committee on District Heating, E. F. McCabe, chairman; report on Lost and Unaccounted-for Current, C. W. Humphrey; report on Purchased Electric Power in Factories, W. H. Atkins, chairman; report on Office Methods and Accounting, Frank W. Frueauff; report on Advertising, La Rue Vredenburgh; report on Sign and Decorative Lighting, Arthur Williams; report on Analysis of Flue Gases, Henry L. Doherty, chairman; report on Standard Rules for Electrical Construction and Operation, Capt. William Brophy, chairman; report of Committee Appointed to Investigate the Steam Turbine, William C. L. Eglin, chairman; Wrinkle Department, edited by Charles H. Williams; Question Box, edited by H. T. Hartman. There are 100 or more "wrinkles" submitted, and the Question Box contains nearly 450 questions, nearly every one of which has been answered. In addition to the papers above enumerated will be the paper on "Underground Construction," for which Past President Doherty will present a gold medal.

The following-named gentlemen comprise the local entertainment committee: James I. Ayer, chairman; Prof. C. A. Adams, Albert Anderson, William H. Atkins, F. E. Barker, F. P. Barnes, R. N. C. Barnes, George H. Berg, H. Bottomley, Capt. William Brophy, F. E. Cabot, C. W. Cartwright, A. E. Childs, A. T. Clark, Prof. Henry E. Clifford, D. P. Robinson, Charles B. Davis, George C. Ewing, H. H. Fairbanks, H. C. Farnsworth, George H. Finn, Almon Foster, W. C. Fish, Charles J. Hatch, Percy Hodges, W. E. Holmes, G. W. Holtzer, Sydney Hosmer, P. J. Kennedy, A. H. Kimball, George B. Lauder, F. W. Lord, Emil C. Lundin, Norman Marshall, E. H. Mather, Everett Morse, H. W. Moses, W. L. Mulligan, J. H. Parker, H. S. Potter, C. B. Price, C. F. Pritchard, Andrew Raeburn, F. H. Raymond, F. S. Richardson, S. B. Condit, Jr., Frank Ridlon, F. P. Royce, G. L. Sadler, F. S. V. Sias, F. E. Smith, Prof. H. B. Smith, J. A. Smith, J. Brodie Smith, George R. Stetson, F. J. Stone, G. M. Stuart, La Rue Vredenburgh, Thomas C. Wales, R. L. Warner, N. T. Wilcox, S. B. Wetherbee, F. S. Wilson, W. C. Woodward.

The following programme will be carried out for the entertainment of the visitors: On Tuesday afternoon the ladies in attendance will take carriages and drive through the Fenway and possibly to some points of interest about Boston. Committee, Charles J. Hatch, W. E. Holmes, D. P. Robinson. On Tuesday evening there will be given at Hotel Vendome a lecture on "Historical and Electrical Boston," under the charge of La Rue Vredenburgh. On Wednesday morning the ladies will visit the shopping district. Committee, H. S. Potter, F. S. Wilson, F. S. V. Sias. On Wednesday afternoon there will be a trip down the harbor, and on return a visit to the L street station of the Boston Edison Company. Committee, Sydney Hosmer, Percy Hodges, W. C. Woodward, Prof. H. E. Clifford. Wednesday evening will be spent at Symphony Hall, attending a popular concert. All the space within the rail has been reserved for the use of the guests and their friends. Committee, R. L. Warner, Thomas C. Wales, R. N. C. Barnes, George C. Ewing, F. W. Lord. On Thursday there will be provided for the ladies a trip in automobiles to Wayside Inn, Lexington and Concord. Committee, C. B. Davis, George H. Berg, F. S. Wilson. On Friday the entire day will be devoted to personally-conducted trips in and about Boston. The business sessions of the association will close on Thursday evening, leaving Friday to be devoted purely to entertainment in the manner above outlined.

A general information bureau will be established at Hotel Vendome, in charge of Messrs. Vose and Peasley, and in addition to the usual duties that such a bureau is called upon to perform, it is intended to have during the week lists made of those desiring to take any particular trips or see any particular points on Friday, so that adequate arrangement may be made for properly personally conducting the visitors to such places as they desire to go.

Mr. W. H. Atkins will have general charge of the entertainment on Friday, and the following committees have been selected to arrange details for the excursions as listed below: Institute of Technology, Prof. H. E. Clifford; Harvard University, Prof. C. A. Adams; Bunker Hill Monument and Navy Yard, P. J. Kennedy; Fore River Ship and Engine Company, Charles H. Parker; Simplex Electric Company, Everett Morss; Holtzer-Cabot Electric Company, C. W. Holtzer; power stations, Boston, I. E. Moultrop; trolley trips, Paul Winsor; N. E. Gas & Coke Company, George H. Finn.

The above briefly outlines the general plan, more definite details of which will be incorporated in the programme, which will be printed a short time in advance of the meeting.

Underwriters to Investigate Fire Causes.

The announcement is made that the National Board of Fire Underwriters—a body comprising about 120 of the most important fire insurance companies, doing business in the United States (which companies have paid out in losses in this country during the last ten years over $750,000,000, not including the recent conflagrations in Baltimore, Rochester and Toronto)—being thoroughly aroused by the continued great and apparently unnecessary fire waste of this country and especially the frequency of sweeping conflagrations in recent years, has undertaken to carefully investigate conditions existing throughout the country, in order to determine if possible more accurately than heretofore, where conditions exist which are conducive to the origin or spread of fire and to co-operate with the government—Federal, State and Municipal—by suggestions for the elimination of such conditions in order to check the present destruction of property so impoverishing to the nation and its citizens.

To carry out this object, a committee has been appointed, known as the Committee of Twenty of the National Board of Fire Underwriters, with instructions to define the congested districts of cities and determine their conflagration hazard, and for that purpose this committee is now organizing a staff of fire protection engineers, who will, after careful inspection, make reports on the construction, fire protection, electric hazard and other local conditions of cities, so that recommendations may be made for the adoption of better building laws, the improvement of water supplies and fire departments and the general safeguarding of hazards including electricity, handling of explosives, etc., etc.

For this work the committee will employ a number of men having had a technical education or training in the different branches of engineering which may fit them for work in such a cause. It is believed that the importance of this work will rapidly increase and that this engineering bureau will be a permanent adjunct of the national board. Men of ability, graduates of technical schools, will, therefore, probably find in such work an agreeable field for their ambitions, especially as few men at the present time have entered the profession of fire protection engineering, in which there seems to be such a promising future. Application blanks for employment on this corps of engineers have been prepared by the committee and can be procured by addressing Mr. Herbert Wilmerding, secretary of the committee, 46 Cedar Street, New York.

Submarine Boat for Japan.

It is reported from Bridgeport, Conn., that the Japanese Government has practically purchased the Lake submarine torpedo boat *Protector*. It is stated that both Russia and Japan made offers for the vessel, but Japan outbid her rival. The *Protector* is now at Newport, R. I.

The Snoqualmie Falls and White River Power Developments.

THE newly organized Snoqualmie Falls and White River Power Company, capitalized at $3,000,000, has acquired by purchase the properties of the noted Snoqualmie Falls Power Company, the Seattle Cataract Company and the Tacoma Cataract Company.

The Snoqualmie Falls Power Company was the pioneer long-distance transmission company in the Pacific Northwest, having a developed capacity of 11,000 hp, which has been in operation three years.

The power generated at Snoqualmie Falls has been distributed through the agency of the Seattle Cataract Company and Tacoma Cataract Company. These two companies owned the franchises and the right to sell Snoqualmie power in the two cities, respectively. They owned the large and handsome sub-stations at these points and the distribution systems throughout the cities, and they marketed the product of the generating plants.

FIG. 1.—GENERAL VIEW AT THE FALLS.

There has been an unprecedented demand for the power generated by the Snoqualmie Falls Power Company. Indeed, this company, both from the viewpoint of the electrical engineer and of the financier, has been an unqualified success. The company's gross earnings have been at the rate of $244,000 a year, and although its prices have been most moderate, its net earnings have been $120,000 per annum, which will be more than doubled after additional capacity is installed. Snoqualmie power is turning the wheels of the many factories and workshops of Seattle and Tacoma, and is running the trolley cars of Seattle, which carry 40,000,000 passengers annually. It supplies power to the Puget Sound Railway Company, commonly known as the "Interurban," which conveys more than a million people between Seattle and Tacoma yearly, and to the Seattle & Renton Railway Company, which carries 1,140,000 passengers annually.

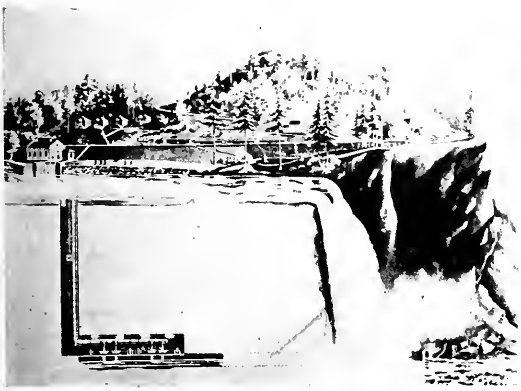

FIG. 2.—SECTIONAL DRAWING OF HEAD WORKS.

To mention divers uses, this power grinds 9,000 bushels of wheat a day at the Centennial Mill and 2,200 bushels at the Hammond Mill, both of which plants are located in Seattle, treats 650 tons of ore a day at the Tacoma Smelter, and runs dentist's burrs in Seattle and Tacoma. It furnishes power for the Washington Iron Works Company, the largest industry of this sort in the Pacific Northwest, and for the Metropolitan Press, of Seattle, which prints most of the papers and periodicals published in this part of the country. It grinds spices and roasts coffee for the Crescent Manufacturing Company, and is the motive force of the Washington Shoe Company, which sends its products all through the Northwest and Alaska. Among other large users of power are the Seattle Electric Laundry, the flour and feed mill, operated by Lehman Bros. in Seattle, and the Tacoma Mill and Fransiola Mill in Tacoma, the hay presses and large feed mill of the Galbraith-Bacon Company and the smelting works and machinery of the large jewelry factory of Joseph Mayer & Bros., of Seattle.

Snoqualmie current furnishes light to the American Steel & Wire Company, for all of the Seattle tracks of the Northern Pacific Railway Company, and runs the motors of its machine shops; to many of the public buildings, stores, saloons and offices in Seattle and Tacoma; and it operates the motors of the numerous small industries of both cities.

Current is supplied to Renton, Kent, Puyallup, Sumner, Swansea, Issaquah and Auburn; and the two last-mentioned cities also obtain their street lighting from this source. Besides supplying Tacoma with most of the power and light for its factories, stores and residences, the Snoqualmie Company also has a contract for the entire city lighting, concerning which the Mayor of Tacoma recently wrote to Mr. Charles H. Baker, president of the Snoqualmie Falls Power Company. "If, throughout your five-year contract with the city, you continue to supply this character of current, you will greatly benefit the city and retain the advanced position you now hold."

FIG. 3.—UNDERGROUND POWER STATION.

Snoqualmie power is also being used by the Great Northern Railway Company in the construction of the important tunnel which it is carrying under the heart of Seattle in order to get its trains off of the main waterfront street of the city, and will light the tunnel both during the creative period and after it is in operation.

Mr. Charles H. Baker, who, in connection with his father, the late William T. Baker, promoted and built the Snoqualmie plant, has taken upon himself an entirely new promotion and development, in harnessing the water power of White River. For this purpose he has organized the White River Power Company, of which he is the chief engineer, and the active manager of its constructional operations. Mr. Baker's Snoqualmie plant is already overloaded owing to the rapid development of the Puget Sound country, and he, therefore, expects to find little difficulty in marketing the product of his White River Company, which already has applications for a considerable portion of its initial capacity. The White River power plant will supply current to the same sub-stations that the Snoqualmie plant does in addition to such new points of distribution as may be determined upon, the radius of profitable distribution being 250 miles in this territory already abundantly supplied with cheap coal and wood fuels. The White River Power Company was formerly owned by the Westinghouse Electric & Manufacturing Company, of Pittsburg.

It is now generally conceded that Snoqualmie River and White River afford the best commercial water powers tributary to the Puget Sound communities. While there are numerous streams in this section of the country—and any stream which has positive direction of flow may theoretically be a water power—yet practically it is unsafe to consider any stream as a commercial possibility unless its volume at minimum flow is ample and unless Nature has, figuratively speaking, done most of the work in the proposed power development, as in the case at both the Snoqualmie and the White River plants. It must not be lost sight of that Puget Sound already affords the cheapest fuels in the world for power in the shape of nearby coal and wood, and the first serious point to be considered by the hydraulic engineer, therefore, in order to protect investors is whether the proposed water power can successfully compete in cost. It is the careful consideration of this condition which bars nearly all the rivers and the streams in the Northwest from having significance as power possibilities. Streams which must be discarded for consideration in Puget Sound, would, if they could be shifted to other fields like California, Nevada and the Central States, where fuels are high, become important industrial factors and wealth producing agencies.

In the foothills of the Cascade Mountains, under the shadow of the snow-capped peak of Mt. Rainier, the White River Power Company is constructing a power plant which is destined to play a very important part in the development of that country, wonderfully rich in natural resources, lying between Portland, Ore., on the south, Vancouver, B. C., on the north, the Cascade Mountains on the east and the shores of Puget Sound on the west. Utilizing the water power of White River, a glacial stream having its source in Mt. Rainier, the company is constructing near Sumner, Wash., a power plant having a capacity of 50,000 electrical hp, of which 10,000 hp will be ready for distribution within one year's time. It will be unequaled in America in size, simplicity and first cost. The varied and multiple uses to which the Snoqualmie power is now being put give, however, only a hint of the demand that exists for electric current in the rapidly-growing section which will be fed by the White River Power Company.

The territory covered by the construction crews of the White River power development extends from Buckley (elevation 660 ft.) in the foothills of the Cascades to Sumner (elevation 65 ft.) lying in the level and fertile lower valley at the White River, a distance of ten miles. The headworks are located about three-quarters of a mile above the Northern Pacific Railway Company's trestle over the White River at Buckley. A concrete dam is being built across the river 9 ft. high and 500 ft. long. This dam will be provided with a sluice gate and automatic flash boards, which will eliminate injury to the dam from floating logs during the periods of high water. An intake 120 ft. wide, located on the south bank of the river, will lead the water into the first section of an open canal. This canal, which is 50 ft. wide and is 5 miles long from the intake to the storage basin at Lake Dorothy, follows an old channel of the White River; and owing to this provision by Nature of a ready-made canal site, it will not be necessary to build flumes at any point of the entire length of the construction work. By the use of four of the largest steam shovels obtainable and 1,500 men this part of the work will be pushed to a speedy conclusion.

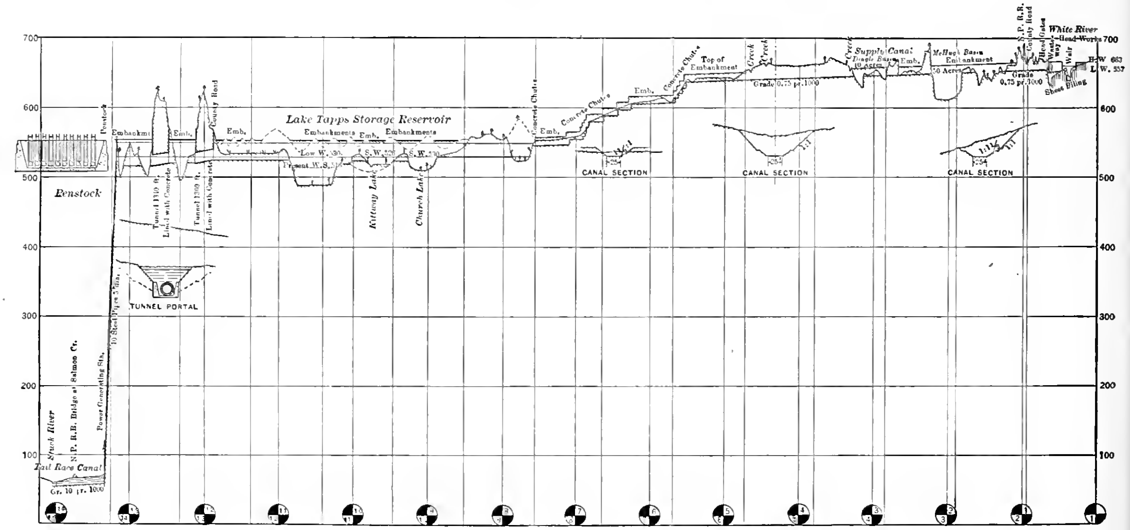

Fig. 4.—General Profile of Snoqualmie Hydraulic Development.

The company is most fortunate in being enabled by the natural conditions to develop an engineering plan entirely eliminating all fluming. All wooden flume features are a disastrous attribute of any power plant, particularly where there is not an extensive storage system as a guarantee of continuous service. The Bakersfield plant in California, which depended upon a two-mile flume, found the service so unreliable on account of the land slides and rock slides taking out the flume, that it penetrated a mountain with a two-mile tunnel through solid granite in order to abandon the flume construction. The longer the flume, the greater the liability to disorders.

The White River plant and the Snoqualmie plant have practically the same elevation of intake, viz.: 660 ft. above sea level. This is a most fortunate situation, for if they were any lower it would be at the expense of head, and any increase in elevation would proportionately reduce the area of watershed and particularly of the rain-fed portion of the watershed. It must be remembered that the Puget Sound rivers derive their winter flow from rains and springs, and their summer flow from snow and glaciers. The higher the intake elevation, therefore, the less the rain area controlled, and consequently the less the power capacity of the river for winter service. Under the load conditions in Seattle and Tacoma, the power requirements are thirty-five per cent. greater in winter than in summer, and the flow at the Snoqualmie and White River intakes responds to these conditions. Another favorable feature of the White River watershed is that the snow and glacier portion of it faces the north, and being thus sheltered from the hot summer sun, the melting is more gradual and later in the year, thus promoting a higher low water stage in the late summer. The Puyallup and Cowlitz glaciers lying upon the southern slope of the mountain disappear much earlier, so that these rivers suffer a more marked and protracted summer low water proportionately.

The first 1,300 ft. of the canal is being excavated along a side hill and will be lined with rubble stones. At the bottom this part of the canal is 25 ft. wide with slopes of ½ to 1, and the water will have a depth of 10 ft. From this point the canal, lined with concrete, crosses the county road, which will be bridged, and tunnels the embankment of the Northern Pacific Railway. Then the canal passes on to a series of alternately narrow and broad benches, which at some remote period formed the bed of the White River itself. These benches are open on the north, the river side, and sloping towards the south they are surrounded on three sides by a higher bench forming the flat part of the main land or plateau. The geological formation of the country, through which the canal passes, is cement and boulder gravel. On this foundation will be deposited by the natural action of the water the white sediment, from which the river gets its name. This sediment is a glacial silt, formed by the scraping of the glaciers of Mt. Rainier on the rock, and its characteristics are such that after it becomes caked it is practically as impervious to water as rubber. By the use of this substance the seepage of the canal will be reduced to a minimum at the outset, and it is expected that within two or three years it will be entirely eliminated.

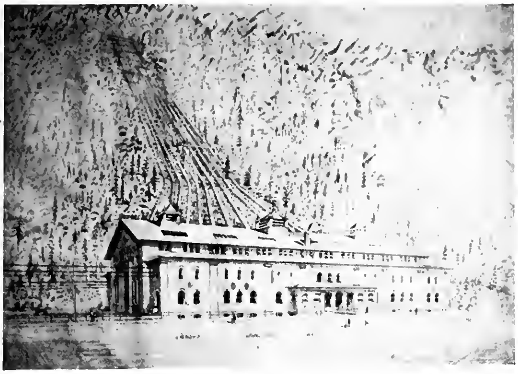

FIG. 5.—WHITE RIVER POWER HOUSE.

The elevation of the intake was so established that it made it possible to lead the canal into four lakes—respectively, Hart Lake, of 8 acres; the McHenry Lake, of 68 acres; the McHugh, of 11 acres, and the Campbell Lake, of 35 acres. In order to supplement the work of Nature it will only be necessary to build several low embankments, the material for which will be furnished by the earth taken from short cuts between the respective lakes. Like the canal these lakes will be rendered water-tight by the deposits of glacial silt. In them the white sediment will be made to settle in order that none of the silt shall be carried into the storage basin at Lake Dorothy.

After leaving the settling basins the water is carried from the intermediate bench through a cut to the high bench, and from this point traverses the main flat country in a westerly direction for 3½ miles until it reaches the Lake Dorothy storage basin. This section of the canal is 100 ft. wide on the surface and 50 ft. wide at the bottom, with slopes of 2 to 1; the depth of water will be 11 ft. To utilize the settling basins, previously mentioned, the location of the intake was so determined that the canal emerges at an elevation of 100 ft. higher than the storage basin. This difference in level will be overcome by guiding the water down over successive chutes to the storage basin. Had the intake been placed so as to avoid the use of these chutes, the canal would necessarily have had to be built along the steep side hills of the White River canyon, thereby entailing the construction of several miles of flumes, a structure that would have been enormously expensive in first cost and maintenance and neither permanent nor reliable.

The White River, while glacial in its origin, is also largely fed by rain and melting snow. During the winter the flow of water is the largest, for it is rarely cold in this part of the country for any length of time, and the warm Chinook winds cause the snow falling on Mt. Rainier and the Cascades to melt rapidly. The floods vary with the precipitation of snow and rain, but the highest flood recorded is 60,000 c.f.s. Only in one month of the year is the flow less than 2,000 c.f.s., the quantity required for the operations of the company on a basis of 120,000 theoretical hp. In October the flow drops as low as 600 c.f.s., and all of this will be taken with the exception of 30 c.f.s., which the federal law requires shall be left in the river to keep the fish alive and for domestic use. During the other months of the year the control gates of the intake will admit only the 2,000 c.f.s. needed to run the company's water wheels.

Through the magnitude of the Lake Dorothy storage basins, however, the company will always have in reserve a vast volume of water for the use of its generating station, which will be constructed in the White River valley, near Sumner below the storage basins. This basin is the most important feature of the whole plan of the White River Power Company, as it is the largest storage basin controlled by any power company in the United States, being only exceeded in capacity by the Great Lakes, which feed Niagara Falls. Another great advantage that this basin has is that it is situated directly over the station in which the water will be used for generating power.

FIG. 6.—VIEW OF TRANSMISSION LINE.

Its location, unlike that of some storage basin remote from the power plant, removes the supply of water from all uncertainties. By the time that the water has reached the storage basin, all dangers from logs and log jams, from breaks in the dam or in the canal or from other causes, are entirely obviated. The Lake Dorothy basin is, therefore, the principal factor in the undertaking of the company.

Until the White River Power Company secured the ownership of the territory surrounding the largest lake, which will be used for a storage basin, it was known as Lake Tapps, the present area of which is 620 acres. In its close proximity are three other lakes, respectively Kirtley Lake, of 80 acres; Church Lake, of 40 acres, and Crawford

Lake, of 20 acres. Like that of the canal right of way and the settling basins, the natural contour of the country around the storage basin is such that it might appear as if Nature intended these lakes for the purpose that the company now proposes to utilize them. The present elevation of Lake Tapps is 515 ft. above the sea level; Church Lake, 530 ft., and that of Kirtley Lake is 526 ft.; but work is now progressing on a series of embankments, making it possible to raise the level of Lake Tapps 35 ft., thus securing a water area of 4,000 acres, which is about seven times larger than the present area. The storage capacity of the Lake Dorothy basin, roughly computed, will be 5,227,200,000 cu. ft., as the average draw-down of water in the basin will be 30 ft. and this means 50,000 hp for two months.

The land controlled by the company, extending from Buckley to Sumner, comprises an area of 6,500 acres. Of this total area 4,000 acres are used for the storage basin, 120 acres are required for the canal and the three settling basins; the headworks cover an area of 10 acres; and the generating station and other buildings in connection with the power plant require 10 acres. A total of 4,140 acres will, therefore, be used in the actual operations of the power company. The balance, 2,360 acres, is controlled by the Lake Dorothy Improvement Company, a corporation organized under the laws of the State of Washington, and will be developed as a pleasure resort by that company.

The power company has a valuable asset in the vast quantity of timber standing on the lands that it has acquired. It has been estimated that the company owns 200,000,000 ft. of timber, 50,000,000 ft. of which is classed among the best cedar standing in the State, and there are over 100,000,000 ft. of fir in prime condition. The canal right of way and basins have been so commonly submerged by the high waters of the White River that forest fires have done very little damage to the timber. Therefore, taken as a whole it is in a better state of preservation than that in most of the sections of the State. To utilize this "by-product," the power company will erect a saw-mill in the White River valley, near the Northern Pacific Railway, which will have a daily capacity of 100,000 ft. It is expected that this saw-mill will be ready for use about the time that the power plant is in actual operation, which will be in one year's time. The output of the saw-mill will be disposed of in the open market, and will largely enhance the company's revenues.

As a result of the submersion of the ranches contiguous to the storage basin, which will be done as soon as the embankments surrounding the lakes are completed, the whole contour of the country will be very much changed. What are now little hills will then be islands, and the valleys between them will be covered with water. These islands and the shores of the lake, an area of 2,360 acres, are controlled by the Lake Dorothy Improvement Company for improvement purposes, which has before it an unparalleled opportunity of building up one of the famous summer resorts of the country. Nature has surrounded the field of its operations with scenery of marvelous beauty. The country, lying as it does in the foot hills of the mountains, is varied in character, commanding a wide view of the Cascade Range and of the fertile White River valley as well. The waters of Lake Dorothy will be studded with twenty-two islands of various sizes, but all of them large enough to be susceptible of improvement for summer residences and pleasure resorts. Lake Tapps now has, for a small lake, a widely diversified aspect, owing to the fact that it has many coves and several long arms, which afford abundant opportunity for exploration by the adventurous, whether in a launch or in a canoe. This feature of the lake will, of course, be greatly intensified when the waters of the storage basins are raised 35 ft., bringing about a seven-fold in-

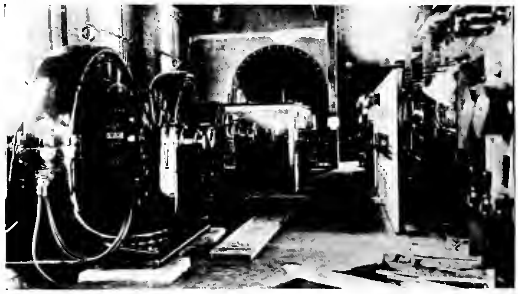

FIG. 8.—INTERIOR OF TACOMA SUB-STATION.

crease in its area. Owing to the fact that Lake Dorothy is only ten miles from Tacoma and twenty-four miles from Seattle, the principal cities of Puget Sound, it will easily be possible to make it a great summer resort. It is estimated that 50,000 people have visited the falls since the company secured the property which it controls. At Lake Dorothy it will be particularly easy to handle large crowds, as the main line of the Puget Sound Electric Railway now runs within two miles of the company's camp, making it necessary to construct only a short spur to reach the lake.

Besides erecting cottages, pavilions and the like, the company will construct a bungalow 68 by 52 ft. on one of the islands, which will be ready for occupancy next summer.

The generating station near Sumner, in the White River valley, will be housed in a two-story building, of which the main dimensions are 219 by 116 ft. This structure will be built of brick, stone and iron, so that it will be practically indestructible. In this building will be located, on the first floor, the office, a carpenter shop, a machine shop and a blacksmith shop. Railroad tracks run through the center of the station to facilitate the handling of the machinery. These will have a spur connection with the main line of the Northern Pacific Railway Company. A traveling crane of 50-tons capacity will be installed which can be operated with ease in any part of the building.

Leading from the Lake Dorothy storage basin provision will be made for ten 48-in. pipes, which will carry water to ten water wheels operating ten generators of 5,000-hp capacity each. All of the electrical equipment of the plant will be of the Westinghouse type. The

FIG. 7.—TACOMA SUB-STATION.

FIG. 9.—SEATTLE SUB-STATION AND OFFICE BUILDING.

water flowing through the penstock will have a net fall of 485 ft. Each bank of three transformers will be housed in a fire-proof compartment. On the second floor of the station will be located the high-tension and operating galleries and the switchboard.

The generators and transformers are connected for operating each set of transformers on their own generators, and also for operating a set of transformers on any generator for emergency cases. Under ordinary operating conditions the generators will be in parallel. Double-break oil switches having a vertical lift of the plunger will be used and will be operated by electric pneumatic control. Integrating wattmeters will be placed on each machine to record

FIG. 10.—BRINK OF THE FALLS.

the total output. Lightning arresters will be connected to the line through switches controlled by electropneumatic cylinders from the switchboard, ammeters being placed in the lightning arrester leads to show when current is flowing through them. In the event of current passing through the lightning arresters, they will be opened by the oil switch and immediately closed, which will usually have the effect of discontinuing any possible arcing and will avoid frequent shut-downs, which occur by the short-circuiting of light-

FIG. 11.—ICE FORMATION AT MOUTH OF TAIL RACE.

ning arresters. A very sensitive center zero reading voltmeter with adjustable resistance in its circuit will be used for watching and holding constant the voltage of the plant.

The face of the switchboard will carry upon it between the instruments a diagram of the connections, the voltmeter being used to represent the generator. Breaks are made in the red line diagram which is thus painted upon the instrument board, and these are backed by red incandescent lamps, the lighting of which will make the appearance of a continuous line through the otherwise open break in the line or bus-bars.

For the use of the officers and employees of the company a two-story building, known as the men's barracks, will be erected near the power house, the main dimensions of which will be 68 ft. by 45 ft. The first floor of the building will provide for a library, a kitchen, a dark room and a chemical room. On the second floor there will be rooms for the president, the superintendent and the housekeeper and seven bed chambers, besides the usual conveniences in way of baths and toilets. There will also be a large attic, which can be utilized for sleeping purposes in cases of emergency.

The White River generating plant will deliver its power into the same transmission system, which is supplied by the Snoqualmie Falls generating plant. This is a most elaborate and substantially constructed system, there being two independent pole lines and two circuits from each generating station, to the two terminals. The transmission is seven-strand aluminum cables, supported on "Imperial" porcelain insulators and the spacing of the wires in each circuit is 9 ft. in the triangle between centers. The aluminum conductors have given most marked satisfaction and the reliability of the service has proved itself unexcelled by any other plant in the country. The transmission is soon to be extended south in the direction of Portland, and north in the direction of Bellingham.

Mr. Baker and his associates have something like two million and a half dollars invested in the various enterprises which he has exploited, and the completion of the plans as they will progress from time to time with the development of the country upon the general scope laid down by Mr. Baker will aggregate an investment exceeding $8,000,000.

New German-American Cable.

The new cable steamship *Stephan* arrived at New York this week from Bremen, bringing 2,300 miles of Siemens cable (4,100 tons) to complete the New York-Fayal section of the German-American duplicate cable. After taking on coal and supplies here the *Stephan* will proceed to the buoy marking the end of the 100-mile stretch of the cable laid last autumn by another of the company's vessels. When the end of the cable is picked up it will be spliced and the *Stephan* will complete the connection with the Azores. The *Stephan* is commanded by Capt. Cornelius and carries a crew of 138 men. She was especially constructed for her present work and is provided with all the modern conveniences and improvements for laying cables. Her displacement is nearly three times that of the cable steamer *Von Podbielski*, her predecessor in the work, while her carrying capacity is nearly five times that of the older vessel. The *Stephan's* capacity is 5,000 tons.

The present German cable by way of the Azores was laid in 1900. It runs from Emden, Germany, to Fayal, and thence to the company's station on Coney Island, just east of the Oriental Hotel. It was determined last year to lay a duplicate cable over the same route. The section from Emden to Fayal has been completed. Only 100 of the 2,400 miles from Coney Island to Fayal has been covered at this end. The system is closely allied with that of the Commercial Cable Company controlled by the Mackays, and Mr. G. G. Ward has given special personal attention to the development of it.

Poolroom Wires.

A sharp and vigorous attack was made last week by the City Club of New York upon the Western Union Telegraph Company for its practice of supplying poolrooms—or race betting resorts forbidden by law—with telegraph service. The club asserts that if the company did not lease its wires to the pool rooms they would have to close their doors. The company asserts that its business requires it to give service to all and sundry without discrimination; at least this appears to be the attitude of the officials and the administration. Some of the newspapers have put in "caps" the names of the directors and have inquired what they mean by it and what they are going to do about it. The rate is said to be $30 per day, and $10 for the operator, and the company, or one of its officers, guarantees "a man who has a large experience, who knows the ropes and knows enough to climb out of the window when trouble comes."

Electricity at the St. Louis Exposition, 1904.

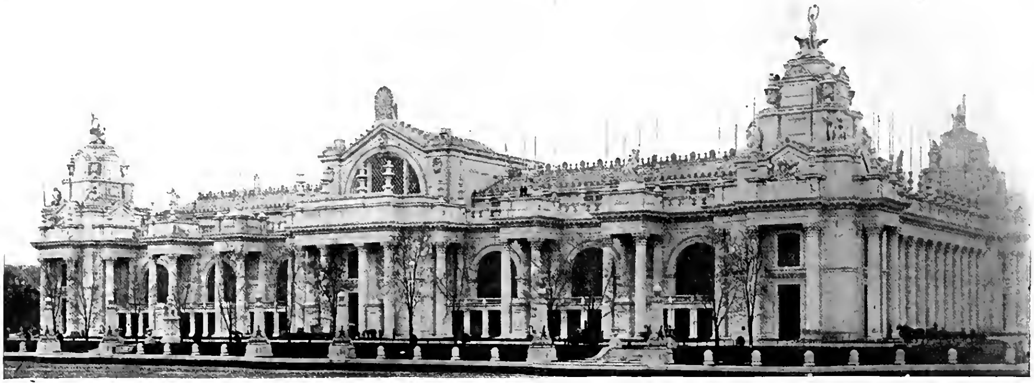

Fig. 1.—Electricity Building.

THE St. Louis Exposition celebrating the purchase of the Louisiana Territory from the Emperor Napoleon by the United States was opened with great ceremony and rejoicing on April 30. Over a hundred thousand people were present on the grounds and elaborate ceremonies marked the occasion, while President Roosevelt, in Washington, in the presence of a large gathering, closed the electrical circuit which released and set the machinery in motion. Our columns have already contained a large number of illustrated and descriptive articles as to this latest and largest World's Fair and we now supplement them by a series of four special articles of a most interesting character with regard to the status of the Exposition at the moment of opening. As will be seen, these articles deal in a general way with the Exposition, outlining its features and comparing it with its predecessors, not only with respect to the application of electricity but also in respect to other details. As usual, the Exposition is not quite ready. One or two of the views which we present are sufficient to demonstrate this fact. No exposition ever was ready when its doors were thrown open to the public and probably none ever will be. There is every indication, however, that when it is at last in full running order the St. Louis Exposition will compare favorably with those which have gone before, particularly in regard to its technical and engineering features. We present herewith also a list of the exhibitors in Electricity Building, although the lists for the various foreign countries are not yet complete. It will be understood that a great many of the electrical exhibitors are also to be found in Machinery Building.

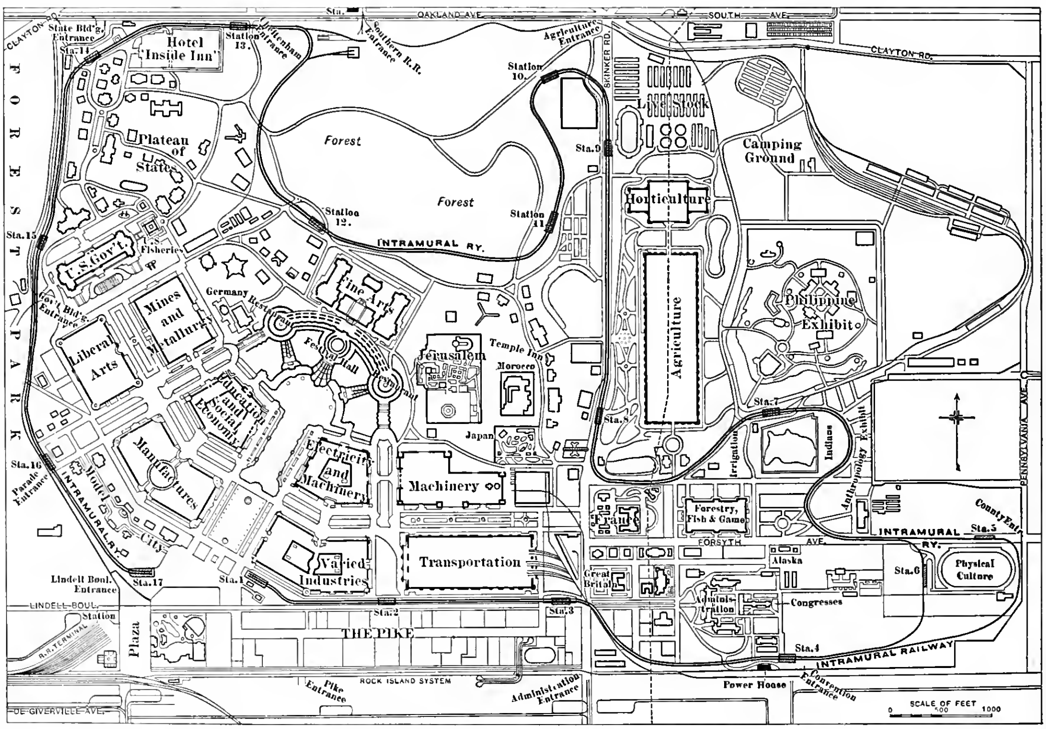

Fig. 2.—Plan of Exposition Grounds, Showing Intramural Electric Railway Line.

Electricity at the Paris and St. Louis Expositions.

By Franz Welz.

THE great international expositions give a splendid opportunity to follow the development of every special branch of human activity. The last one was that held at Paris in 1900. In the time which has elapsed between that and the International Exposition in St. Louis in 1904 much progress has been made along some lines, especially electricity. It must be remembered that, even the Paris Exposition, which was in many respects the most complete representation of the civilization of the whole world, could not give an entire picture of the development in every line of human activity. As to electricity, only Germany, France, Belgium and Switzerland really showed fully what they were able to do in this line; whereas, the electrical industry of the United States and Great Britain was not sufficiently represented to give a proper conception of their standing in this special branch. England was handicapped by the South African war; in the case of the United States, the great distance between the two countries, in addition to the loss of the *Pauillac,* was the principal reason of inadequate display. At the St. Louis Exposition, as to the European countries, the long distance and the high cost of transportation has excluded all the heavy pieces of machinery and apparatus. The Russian-Japanese war and the depression in the commerce of Europe explain fully why the European exhibits in the Electricity Building at the World's Fair at St. Louis, do not give a full idea of the standing and the possibilities of the electrical industry in the countries on the other side of the ocean. On the other hand, it is noticeable that progressive Japan and the South American countries are participating to a larger degree in the electrical display at the St. Louis Exposition than they did in Paris. Whereas, Japan exhibited in Paris only some drawings, etc., concerning the governmental telegraph system, this country occupies at St. Louis a space of twelve hundred square feet in which several Japanese firms exhibit dynamos, motors, chandeliers, electroliers, telegraphic instruments, measuring instruments, instruments for electromedical use, etc., which are all designed by Japanese engineers and manufactured in that country. How far Japan has advanced in the electrical industry is shown by the fact that it is also exhibiting a high-tension transformer for 150,000 volts for testing purposes.

The St. Louis Exposition impresses the visitor especially by its magnitude. While the Paris Exposition occupied altogether an area of only five hundred and twenty-five acres, the World's Fair at St. Louis is extended over 1,240 acres; that is, two and one-half times the area of the Exposition at Paris. The total cost of the Paris Exposition has been calculated at $21,500,000. As to the St. Louis Exposition, no definite figures are yet available, but it is estimated that the total expense will amount to nearly $50,000,000.

A special feature of the St. Louis Exposition is the magnitude of the power station, generating current for the decorative illumination of the buildings and also the electric light and power for commercial use of the exhibitors. A summation of the output of the machines installed in the Machinery Hall, with the added energy furnished by the Union Electric Light & Power Company, of St. Louis, results in a total of 46,000 hp for this purpose. At Paris the total amount available for light and power purposes was 20,000 hp, of which 7,000 hp was generally used in day time and the full amount of 20,000 hp only on special days for illumination purposes.

The incandescent lamp is used to a very large extent at St. Louis for decorative lighting of the buildings, the Cascades, the main feature of the Fair, the bridges and lagoons surrounding these buildings. The architectural lines of each building are brought out into bold relief by thousands of 8-cp incandescent lamps, and 250,000 of these lamps are altogether used for this purpose, not including the energy used for the illumination of the Cascades, which amounts to 2,100 kw. Compared with these figures, the electric lighting display at the Paris Exposition does not make a very great show. With the exception of the "Chateau d'Eau," where about 1,200 hp was utilized for lighting effects, the statue of "L'Electricité" and the statue of "La Parisienne," very few incandescent lamps were used for decorative illumination at Paris; and outside the energy for commercial use, most of the current was employed for arc lighting in the streets of the Exposition. The total number of incandescent lamps used for decorative illumination at Paris was 76,720.

FIG. 3.—STATUE OF FRANKLIN IN FRONT OF ELECTRICITY BUILDING.

FIG. 4.—STATUE OF JOSEPH HENRY.

As to the means of transportation on the Exposition Grounds, St. Louis shows some new features compared with Paris. Besides the Intramural Railway, common to most of the Expositions, there will be an extensive use of electric automobiles and the electric push chair.

In regard to the electrical exhibits themselves, St. Louis also brings forth several new ideas. In most of the former expositions, the exhibits consisted of finished machinery and apparatus which were merely brought before the public as "dead" exhibits (not in operation), but at St. Louis it is the endeavor to show to the public the methods of the manufacture and this way of exhibiting is always far more instructive and attractive. There will be in St. Louis quite a number of these working exhibits. One of the most striking of these is an incandescent lamp factory in full operation.

In comparing the Exposition of 1889 at Paris with the 1900 Paris Exposition, the most striking fact was the increase in size of direct-current and alternating-current machines. It was the aim of the large European electrical concerns to have the largest electrical machines possible at the 1900 Exposition. But since 1900 the size of the alternators shown at Paris has been increased nearly three times, and the engineering world has become so much accustomed to large units, this phase of the development does not constitute any longer a feature for an exposition. The alternators generating the power at the Exposition in St. Louis are not of exceptionally large capacity, and the only new features in this respect are the large steam turbines and gas engines, both of which have increased considerably in size since the Paris Exposition. These two prime-movers are entering more and more into the field of machines for generating power. Different systems of both these types will be seen at St. Louis and there will be ample opportunity to study their advantages and mechanism. In the construction of alternating-current dynamos the tendency prevailed to produce as near as possible sine waves, and many

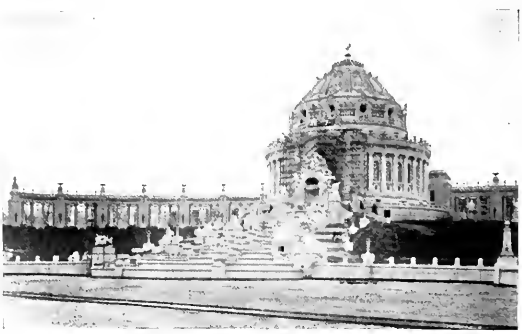

FIG. 5.—CASCADES—THE ELECTRIC FOUNTAIN.

new devices have been proposed and accomplished in this direction since the Paris Exposition. Another remarkable change in the construction of electrical machinery since the Paris Exposition is in the decrease of weight and price of electrical dynamos and motors sustaining at the same time the same quality and durability. This fact is illustrated in a very striking manner by the two sets of curves shown taken from the data of one of the most successful German electrical firms. These curves are laid out in such a way that two of them give the number of kilograms used per kilowatt, whereas the others give the cost in marks (4.2 marks equal $1.00) per kilowatt. In order to make the comparison correct, the kilowatts are reduced to thousand revolutions. These curves show that, compared

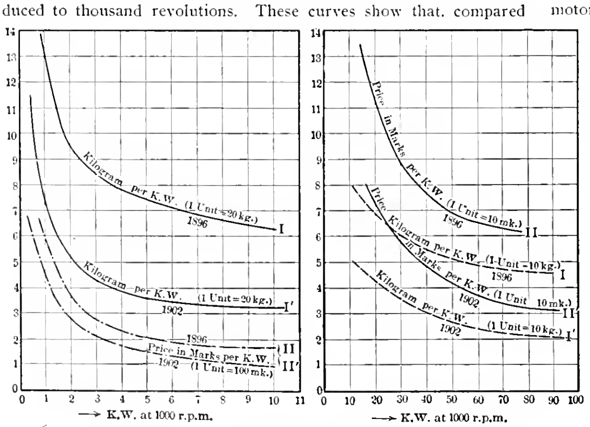

FIG. 6.—CURVES SHOWING CHANGES IN CONSTRUCTION OF ELECTRICAL MACHINERY.

with the year 1896, the same output of kilowatts is now obtained with only half the material used at that time.

As to direct-current dynamos, we see some improvements since 1900, inasmuch as the armature reaction and the distortion of the magnetic field have been remedied by the compensation winding of Déri and others, and a very important use has been made of this new feature in employing electric machinery for hoisting in mines, where it is necessary to regulate, under the full current, the voltage in the shunt from full voltage down to zero, and then reverse. This gives new possibilities for the employment of electricity in mines, etc. The greatest progress which has been made since the Paris Exposition, and to which the Exposition at St. Louis will bear eloquent testimony, lies in the single-phase field. The cause for this advance was the increasing demand for a practicable electric system for long-distance electric railways. The variable-speed, single-phase motor was the long-looked-for solution of this vital problem. It is gratifying to state that several types of this motor have been devised recently both on this side of the ocean and in Europe. At St. Louis

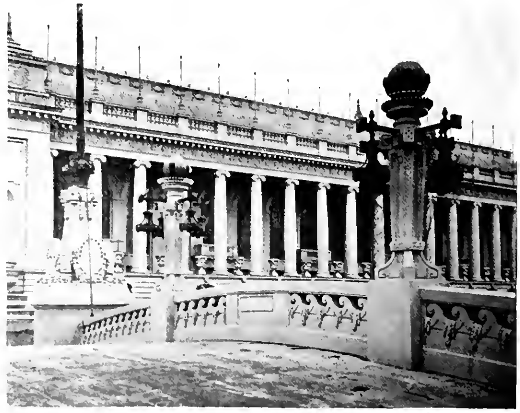

FIG. 7.—BRIDGE, SHOWING ILLUMINATION LAMPS USED ON GROUNDS.

there will be ample opportunity to see these new motors in operation and engineers will have a chance to convince themselves as to their fitness for the railway service. The experience gained by the trials at the Berlin-Zossen high-speed electric railway seems to indicate that the system best adapted for this purpose is that which allows the direct application of high voltage to the motors. This system decreases the weight of the car, as no transformers have to be carried; it has the added advantage of making the erection of transformer sub-stations unnecessary at different points of the line, the whole line being under high tension. These considerations led at the Berlin-Zossen trials to the construction of 10,000-volt, three-phase motors, which were tested on this line in the beginning of 1902, and gave entirely satisfactory results. Another new step in the alternating-current field which will be demonstrated at St. Louis, and which will probably prove to be of far-reaching importance, is the compensating of alternators worked out by Mr. Heyland, and his still more promising latest invention: the compounding of synchronous machines. The results obtained with these machines were so favorable that several European firms and also one of the American electrical manufacturers have taken up the construction of these new types, which are now being built up to a capacity of 1,500 kw.

Quite a new departure in central station development promises to become the commercial application of the Cooper Hewitt converter. The reports which so far have been obtainable show such remarkable advantages as to efficiency and size, that, if these reports hold practicable, it would mean a revolution in a large part of the electrical industry. It is understood that the company exploiting these patents will give at the St. Louis Exposition full proof of the promised qualities of this new apparatus.

Other forms of converter which aroused new interest lately are the Noden and Grisson-Walter electrolytic types, which seem to have an efficiency of 75 per cent. The rotary converter, which was exhibited at the Paris Exposition, only to a very small extent, will be a large feature at the coming fair, and European engineers less familiar with this type of machine will have opportunities of getting convinced of the excellent qualities of these machines and their feasibility for sub-station work. As is well known, the European practice tends more to the motor-generator, and the general opinion there is that it is in many respects superior to the rotary converter.

FIG. 8.—MONUMENTAL FOUNTAIN, PARIS EXPOSITION, 1889.

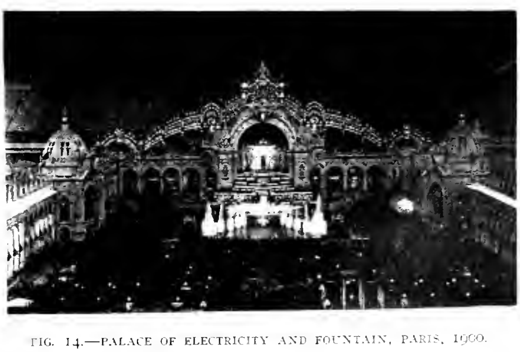

FIG. 14.—PALACE OF ELECTRICITY AND FOUNTAIN, PARIS, 1900.

EXAMPLES OF BUILDINGS, LIGHTING EFFECTS, ETC., AT FORMER EXPOSITIONS.

A very interesting and novel exhibit in the line of electric machinery will be a model testing floor in the Bullock space, which will be equipped with the most modern instruments, and will give a fair idea of the excellent equipment of American electrical factories.

Some additional new features will be seen at the St. Louis Exposition concerning the development of the electric railway since the Paris Exposition. These are largely along the line of high-speed and will be represented at St. Louis by models and drawings, such as the mono-railway "Behr" system, for 110 miles per hour, the suspended electric railway system of Langen employed in Elberfeld, the high-speed electric railway system employed at Berlin-Zossen, and several other suspended electric railway methods. The question at present is as to whether or not such high speeds as 125 miles per hour are practical; and, as soon as this question is fully decided, the superiority of either one of these systems must be proved. According to recent reports, the Langen system affords the possibility of speeds up to 200 miles per hour with perfect safety, disregarding other advantages.

At the Paris Exposition there was manifested a marked tendency for creating uniform types of electrical machinery and apparatus, all over the world. Since that time this tendency has taken more practical form, and the proposition has been made to treat this question elaborately at the Electrical Congress during the St. Louis Exposition. This proposition tends to establish standard rules for measuring and testing electrical machinery, and it is to be hoped that this end can be reached, as it would simplify to a very great extent the commercial and scientific negotiations between different nations, and greatly help the advancement of the science and industry.

In the field of electrochemistry the Edison iron-nickel storage battery will make its appearance at the Exposition. The methods of storing electricity are not as yet of very high efficiency, and it would mean a very great advance if an accumulator could be built which, with small weight and great durability would permit the storing and quick discharge of a considerable amount of electricity. Whether or not the Edison accumulator possesses these qualities to the extent that has been reported will be proven by the results obtained from the exhibit at St. Louis, and definite facts will doubtless replace the hypothetical opinions concerning this battery. In comparing the electrochemical display in St. Louis with Paris, it may be remembered that at the Paris Exposition electrochemistry formed for the first time a special group, and many of the electrochemical processes were only shown in their very first beginnings. At St. Louis will be exhibited many of these processes, such as electrical water purifying, electroengraving, electrical gold extraction, etc., that have been developed to a great state of perfection, and the names of Goldschmidt, Nernst, Ostwald, Drude, Siemens & Halske, Bradley, Hall, Cowles, Acheson, etc., will stand at St. Louis for the great advance made in this line.

In the field of electric illumination, the perfection of incandescent lighting and similar systems has not yet been reached to the full extent. Progress has not been as rapid as was hoped, but still it must be said that the Nernst lamp has been improved greatly since Paris. This lamp appeared publicly for the first time at Paris, being there lighted primarily with a match, and showing very many imperfections, so that it could be only employed to a small extent even as an exhibit. As the Nernst lamp stands to-day, it is already holding a very important place between the incandescent lamp and the arc lamp as a pure, brilliant illuminant. The state of practical perfection at which this lamp has arrived is best illustrated by the fact that it does not by any means figure at St. Louis merely as an exhibit, but is employed commercially for numerous electrical installations; while there will be used altogether more than 12,000 Nernst lamp glowers in buildings and exhibit pavilions on the World's Fair grounds. It is much to be regretted that the invention of Auer, the "osmium lamp" has not yet proved to be a full success, and hence the St. Louis Exposition will be deprived of the opportunity to show this lamp. Instead of this, however, the Cooper Hewitt mercury lamp will be brought for the first time before the eyes of the public, in a large way in its various applications for lighting and other purposes. There is no doubt that this strange, brilliant illuminant will attract the attention, not only of the great public, but also of the artisan and engineer.

FIG. 15.—NIGHT VIEW OF ELECTRICITY BUILDING, ST. LOUIS.

A very attractive novelty in decorative lighting with incandescent lamps will be demonstrated in the so-called "pearl system," an invention of Mr. G. Weismann, of Paris. This adapts itself very nicely to all kinds of electroliers and specialties for garlands. The circuit is formed by bare wires, each one surrounded by small pearls creating a very effective insulation. In connecting the lamps it is only necessary to introduce between two pearls a wire attached to the main wire by a hook, the two wires leading to the incandescent lamp also being insulated by small pearls. The lamp does not possess any socket, and the wires enter the bulb directly.

As to arc lamps, some progress has been made in bringing out small types of high reliability. The greatest difficulty is that this system does not possess the same simplicity in operation and construction as the incandescent lamp. Considerable improvement has been made in these respects and the inventions of the Italian engineer, Rignon, and others, will prove the fact at St. Louis. The Bremer arc lamp was shown for the first time at the Paris Exposition, as at that time one of the latest inventions in the art of electric lighting. Since then many improvements have been made in it and the lamp has found large application all over Europe. The Westinghouse Company has acquired the patents and will show this new type of lamp at the St. Louis Exposition in its latest state of perfection. It may be remembered that, in these lamps, carbons of special preparation are used for the purpose of increasing very considerably the amount of light per watt. This special treatment of the carbons has the added effect of softening the light and making it more agreeable to the eye. Other types of lamps of foreign construction will be exhibited by Siemens & Halske, etc., and M. Blondel, of Paris, who will show his new type of flame arc lamps.

An interesting feature at the St. Louis Exposition for the European electrical engineers will be the largely represented series alternating arc systems, as worked out by the General Electric Company, the Western Electric Company, the Fort Wayne Electric Works, and others. This system is very seldom employed in Europe, where for arc lighting installations on a large scale the shunt system is mostly used.

Nothing of especial importance has been invented in the way of distribution; but it might be mentioned that, since the Paris Exposition, the 220-volt incandescent lamp has come into more extensive use and has attained a very high efficiency. The improvement of this type of lamp has developed the more extensive erection of central stations of 220-volt voltage, and the use of a three-wire system of 440 volts between the outside wires and 220 between the outside and neutral. To the list of lightning arresters, a valuable addition has been made in the Siemens & Halske so-called "Hoernerblitzableiter." Another new invention in this direction is that of the Italian engineer, Fala, who will show at the St. Louis Exposition his new lightning arresters in series, with which very good results have been obtained in the large Italian high-tension central stations.

Telephony and telegraphy will make a very creditable showing at the 1904 Exposition. The great advance in these branches is largely due to the liberal patronage accorded them in the United States. The American Telephone & Telegraph Company, of Boston, will demonstrate in a special building with a very artistic exterior the development of the inventions of Prof. Bell and others from the very beginning up to the present time; and several other "independent" American companies are exhibiting their latest and best types of apparatus, including automatic telephone systems, in which class the Faller takes a very prominent place. At the time of the Paris Exposition, these automatic systems had not reached a very high grade of perfection, but at the present time the solution of this problem becomes more and more imperative, and such systems are being worked out in great numbers, and of notable ingenuity.

One of the prominent places in the Electricity Building and the Exposition at St. Louis as a whole, will be occupied by the wireless

FIG. 16.—VARIED INDUSTRIES BUILDING AT NIGHT.

telegraph stations of the American De Forest Wireless Telegraph Company, of New York. At the time of the Paris Exposition the principles of wireless telegraph were known, and quite a number of apparatii were shown there. The De Forest wireless station at St. Louis is of considerable magnitude. In the Electricity Building three towers of seventy-five feet each in height have been erected, whence messages will be sent to the wireless telegraph station in the "Model City" of the World's Fair grounds. Another mast of 200 ft. high with 50-ft. outriggers, is put up near the site of "Jerusalem," and a steel tower of 325 ft. near the Press Building. From these stations it is expected to send messages to the neighboring cities. In addition to the De Forest Company, the wireless transmission of electrical waves has been exploited by many inventors and firms, since 1900, and wireless apparatus for different purposes are shown at St. Louis by the French engineer, M. E. Ducretet, by T. E. Clark, of Detroit, and the Italian, Professor A. Artom. Besides wireless telegraphy, a new feature will be the demonstration of wireless telephony by A. F. Collins and M. R. Hutchison. It may be remembered that at the time of the Paris Exposition none of these systems were in use, thus giving St. Louis the distinction of showing them as part of the practical art for the first time. It is to be regretted that in addition to these systems the German inventor, Ernst Ruhmer, has

FIG. 17.—LOOKING TOWARD ELECTRICITY BUILDING.

not been able to bring to this country his apparatus for wireless telephony, based upon the action of light rays upon the selenium cells. This inventor has succeeded in talking over a distance of about six miles and has also succeeded in effecting long-distance telephonic communication between ships.

In the section of various applications of electricity there are also some new departures comparing St. Louis with Paris. The great number and variety of electrotherapeutic apparatus is striking and gives the best proof of the high value of electricity for special medical examinations and treatment of certain cancerous diseases. For the first time it will be shown publicly at the St. Louis Exposition how the ultra-violet rays of the arc lamps, the chemical rays, can be used successfully for the cure of the most obstinate cases of "lupus vulgaris" and similar diseases. The Danish physician, Prof. Niels R. Finsen, must be credited with having introduced this new method for the first time, and its application is quickly spreading all over the world. France, in which country the radium was discovered and thoroughly studied, has the honor of exhibiting for the first time in St. Louis the different apparatus for the investigation of this wonderful element, of which apparatus the "Spinthariscope," showing the scintillations of the radium, is the most interesting. Another new application of electricity in the medical field is the "Acousticon" and the "Massacon" inventions of Mr. M. R. Hutchison, which aroused so much admiration all over the world. These apparatii make it possible to teach the deaf mutes to hear and to speak.

In the line of electrical instruction the St. Louis Exposition can also show a typical American novelty, nearly unknown to the European practice; that is, "the American School of Correspondence." The exhibit of this institution will give full testimony of the success which has been attained by this unique method of teaching, speaking for its excellency and the ability of the promoters. It must be admitted that for a certain class of students and under the peculiar conditions of such a large country as the United States, this method of teaching certainly has its right of existence.

When the most prominent electrical engineers of the world assemble in St. Louis during September, for the International Electrical Congress, they will look with pride upon the brilliant electrical display; and in viewing the exhibits in the Electricity Palace, they will be impressed with their highly technical value, and the imposing and systematic arrangement. The whole will be a full and worthy demonstration of the progress made in electrical science and industry since the Paris Exposition of 1900.

The Installation of Exhibits in the Electricity Building, St. Louis.

By Cloyd Marshall.

The construction of booths and the installation of exhibits are proceeding rapidly in the Palace of Electricity and on the opening day, April 30, this building was ready for the reception of visitors. To get all the exhibitors to ship machinery and begin construction in time for completion, before the gates open, is one of the difficult problems of every exposition. At St. Louis the department buildings have been constructed for some time and the Palace of Electricity has been under cover for ten months. Every effort has been made to impress upon the exhibitors the advantage of coming early to avoid the rush of the last one or two weeks before the opening. The Electrical Department has met with ready response and co-operation from the electrical manufacturers.

By reference to the installation plan of the Electricity Building the outline of exhibits may be followed. In the gallery over Sections 1 and 2 are the offices of the department, jury and committee rooms. With this exception there is no second floor to any part of the building, all exhibits being on the ground floor with ample head room. The cone of the roof is about 75 ft. above the floor, with skylights and monitors which give abundant light and ventilation. In Section 1 facing Aisle B are the offices of the Electrical World and Engineer. Telegraph exhibits and the main Exposition offices of the Postal and Western Union Telegraph offices occupy the same locality. High-speed telegraph systems are to be shown in operation by Patrick B. Delany and Walter P. Phillips, while Charles E. Yetman will exhibit a transmitting typewriter applied to telegraphic work. The Gray telautograph, or writing telegraph, reproducing at a distance writing and drawings, will be in operation.

Near the center of Section 4 is located the sub-station which contains transformers, switchboards and rotary converters through which the high-potential alternating current is received from the service power plant and transformed to a lower voltage or converted to a direct current for distribution throughout the building, to be used for lighting and the operation of exhibits. This machinery was furnished chiefly by the General Electric and Westinghouse Electric & Manufacturing Companies. Adjoining the station the latter company is installing one of the largest exhibits in the building, embracing the varied branches of electrical machinery and apparatus. Across Aisle B will be the electric railway trucks and locomotives of Burnham, Williams & Co. Along the north side of Section 3 the Standard Underground Cable Company and the McRoy Conduit Company are installing a model conduit system, as used in the best city construction, and will show the method of placing cables in the conduits. A very conspicuous object is to be a Burdette-Rowntree electric dumb waiter running from the floor to the roof above Section 3. Its operation is automatic, starting or stopping in response to a push button.

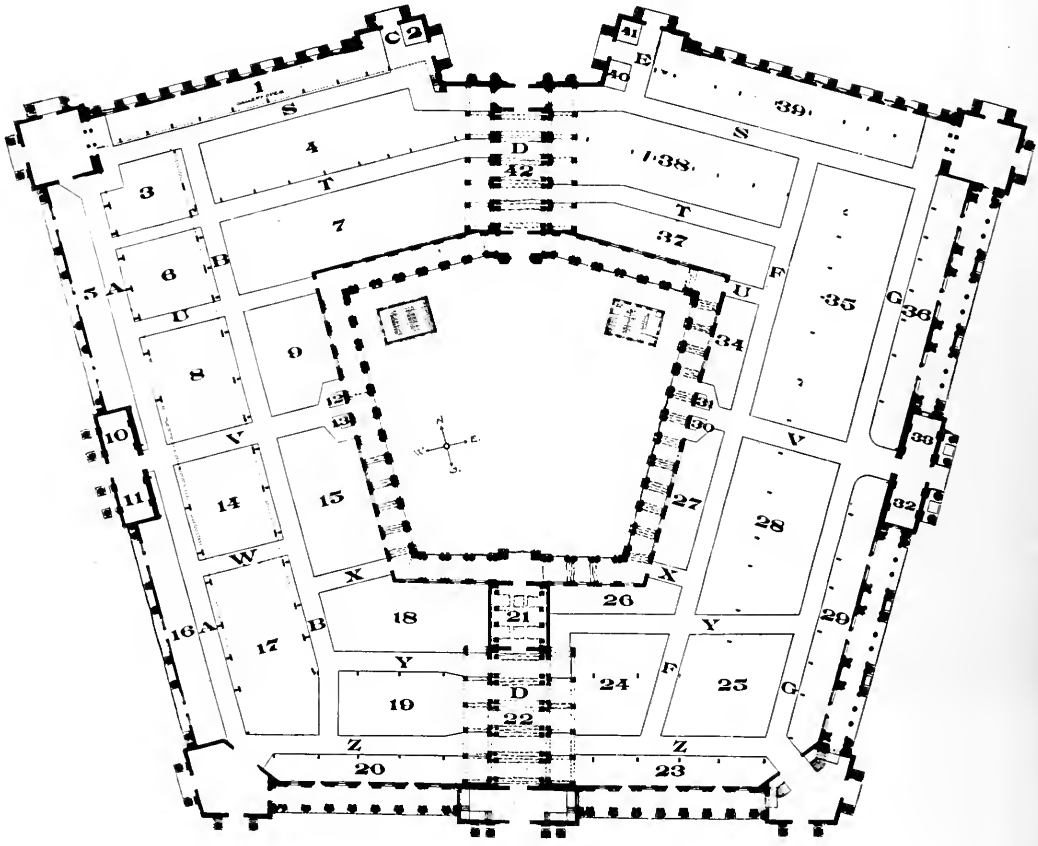

Fig. 18.—Plan of Electricity Building.

Over Sections 3 to 17, along the west side of the building, is the craneway with a span of 57 ft. 5½ in. Upon this is a four-motor, 30-ton electric traveling crane furnished by Pawling & Harnischfeger. A 20-hp, 220-volt motor gives a horizontal speed of 250 ft. per minute, and an 8-hp motor gives a trolley transverse speed of 150 ft. The main hoist is equipped with a 30-hp motor with a speed of 25 ft., and the auxiliary hoist with a 15-hp motor, and has a travel from 30 to 90 ft. per minute. The crane has proved very serviceable in the installation of exhibits and will be used in handling heavy machinery when exhibits are dismantled. With one exception the heavy exhibits are to be installed under or adjoining the craneway.

In the northwest corner are several displays of electric railway equipment. The electric and air brake apparatus of the National

Electric Company is shown as well as a line of alternating and direct-current generators and motors. Block 9 is equally divided between the Fort Wayne Electric Works and the Wagner Electric Manufacturing Company, both putting in working exhibits. The Fort Wayne display consists of a line of direct-current machinery, transformers, fan motors, wattmeters and a series arc light system. The Wagner space contains a variety of single-phase alternating-current power motors running under different conditions, motor-generator sets charging a storage battery, static transformers and indicating switchboard instruments.

The remaining space adjoining the court is occupied by the Bullock Electric Company and it is one of the notable machinery exhibits. A 6,600-volt alternating current is received and transformed to 340 volts for a rotary converter to supply 500-volt direct current for operating street railway apparatus. Other motor-generators and balancing sets furnish current for multivoltage systems as applied to speed control for machine tools. The individual feature of this exhibit is a model testing floor, indicating the best methods of testing electrical machinery before it goes to the customer. Under the traveling crane the Northern Electrical Manufacturing Company will have the most complete demonstration of the adaptation of electric motors to every form of tool. In this exhibit the manufacturing of motors is to be carried out in a way to show the convenience and increased efficiency of motor-driven tools. All of Block 17 under the crane-way is taken by the Western Electric Company. Near the center is a large 100-kw motor-generator set which, with a compensator, furnishes 110 and 220-volt direct current throughout the exhibit. Next Aisle B is a small machine shop in operation, showing the direct application of motors to tools. There are to be several direct-connected marine sets, transformers and regulating apparatus. On the opposite side is to be a series alternating arc light equipment with ornamental lamps and stands.

There are two collective exhibits, embracing nearly all electrical classifications, one by the Wesco Supply Company, of St. Louis, in Block 8, and another by Ewing-Merkle covering a portion of Block 14. In the former a large Warren synchronous motor drives a Triumph generator supplying power for the motors and apparatus in operation. In the second exhibit the Commercial Electric Company will have a number of direct-current motors from 1¼ to 35 hp, a 30-kw, three-bearing generator direct-connected to a gas engine, furnish power for the other exhibit items. A special feature is a line of variable-speed motors designed for operating on any standard two-wire system, with single voltage, and which will give speed variations of from 4 to 1, with horse-power and efficiency practically constant at all speeds, and little if any variation of speed at all loads with the controller set at a given point.

The western entrance embraces two large spaces, which are occupied by unique exhibits. The Carman Projector & Specialty Company will show stereopticons, lanterns, projectors and automatic electric curtain hoists in operation. Opposite is the electroplating exhibit of the Hall Gold & Silver Plating Works. The different processes of plating and finishing of plated wares are to be shown in a most attractive manner. The Gould Storage Battery Company and the Gould Coupler Company are installing a fine combination exhibit in Section 16, which includes motor-generator sets and rotary transformers to charge storage batteries, to be arranged so that many ingenious applications of batteries to different lines of work will be illustrated. An interesting item is a motor-driven unipolar dynamo, charging two immense cells at from 3,000 to 5,000 amp. at about 5 volts. In the northern half of Block 16 is being placed the artistic exhibit of Japan. This electrical apparatus was designed and made by Japanese, most of whom received their education and training in this country. The Italian space, occupying Block 18, is especially worthy of notice on account of the scientific and electrical measuring instruments therein. A model central station storage battery plant in a fire and acid-proof enclosure is now being placed by the Electric Storage Battery Company. A conspicuous feature is an immense map of the United States showing the location of between 1,600 and 1,700 plants installed by this company, the railway, lighting, telephone and isolated installations being indicated by different colored

FIG. 19.—ENTRANCE TO ELECTRICITY BUILDING.

lamps. The Porter Battery Company will have a battery on exhibition which has been in constant service over eight years, and another which made a record automobile run of 187 miles on one charge.

The three 75-ft. towers of the De Forest Wireless Telegraph Company are erected and will support the antenna from which wireless messages can be sent and received from other stations in the building and the large station in the model city. The T. E. Clark Wireless Telegraph-Telephone Company shows a line of wireless apparatus in operation, and the adaptation of such apparatus to fire alarms and safety signalling on railroads. Two wireless telephone stations at opposite ends of the building will be used by A. F. Collins to demonstrate the newest application of electricity to the transmission of intelligence. Two telephone operating exchanges are in the south side of the building, both enclosed by handsome booths. Section 17, not covered by the crane, is occupied by the exchange of the American Telephone & Telegraph Company. This connects with the local and long-distance lines of the Bell Company, so that there is direct communication from the building to all parts of the grounds, city and all points reached by telephone lines. In Section 24 the exchange of the Kellogg Switchboard & Supply Company gives a floor space. A great variety of electrical apparatus manufactured by this company is now being installed and will be shown in operation. The Edison exhibits are in Sections 26 and 27, and include the iron-nickel storage battery and a historical collection of great merit.

The purification of water by electricity is shown by the Standard Water Purifying Company, in Block 33, and water absolutely free from all forms of organic life will be served to visitors. Electro-therapeutic apparatus represents one of the most beneficial adaptations of electricity, and the latest developments in this line are shown in Section 4, by the representative manufacturers of such apparatus. In the northeast part of the building are the German and French collections of electrical exhibits; the former is especially strong in electrochemistry. France has the most comprehensive display of any foreign country, covering as it does every classification. In the eastern half of Block 7 England is making an excellent showing of its electrical products.

This outline of the exhibits being placed in the Electrical Building is of necessity incomplete at this time. Many companies now preparing displays have not proceeded far enough with their installations in the building that an account can be given of their displays.

Fig. 20.—A View of Electricity Building by Night.

similar service through its connection with the Kinloch system, of St. Louis. Recent developments of automatic and semi-automatic telephone systems are to be shown in a thorough manner by the Automatic Electric and the Fuller Automatic Telephone Exchange Companies. An instructive historical collection of telephone apparatus is to be arranged by B. F. Wasson in Block 25.

In a fine booth erected by the Hutchison Acoustic Company will be exhibited the "Acousticon" and "Massacon," giving daily exhibitions of deaf mutes being made to hear and taught to speak through their instrumentality. M. R. Hutchison will also demonstrate a wonderful adaptation of the wireless telephone. Around the court of the Electricity Building is a circuit of wires connected to the booth in Block 23. Before a telephone transmitter in the booth, music will be played. In the court no sound of this is heard until a pocket telephone receiver, without any wire connection is placed to the ear and then the music becomes audible. At any point in the court music can be heard by the aid of the receiver.

Two beautiful booths in Section 25 are those of the Holophane Glass Company and the Weston Electric Instrument Company, the latter showing a full line of standardizing electrical instruments. The brilliant illumination of the Holophane exhibit will be most conspicuous, as 1,000 incandescent lamps cover the exterior and interior of their handsome structure. The laboratories of the National Bureau of Standards, covering a space of 23 by 200 ft., will contain over $50,000 worth of instruments for testing every kind of electrical machine and apparatus. About twenty government experts are connected with the laboratories to conduct tests and investigations. No preceding Exposition ever had such facilities for making complete records or assisting the juries in their awards.

The largest individual exhibit is that of the General Electric Company, embracing Section 28, and covering a quarter of an acre of However, it will be apparent by the foregoing that American manufacturers will far surpass any previous effort, and that the electrical exhibits at St. Louis will be a source of pride to all those interested in the industry. By the time this article appears most if not all of the exhibits will be in good shape, ready for inspection.

The "Pike" at St. Louis.

One of the most famous features at the World's Fair in Chicago, in 1893 was the Midway. It is safe to say that everybody went there, whatever else they did not see. In like manner the St. Louis Exposition has its happily named "Pike," and a more extraordinary or fascinating collection of side shows was never got together under the sun. It is estimated that $5,000,000 has been spent on the attractions, while the number of performers is put at 6,000. Forty or fifty dollars can easily be spent doing all the attractions properly. It is true that many of these shows have been seen at other Expositions, but they will probably be new to a majority of the visitors, and some of them are well worth a visit more than once. It is interesting to note that in nearly all of them, electric lights and motors are freely used; in fact some of the most novel and brilliant effects depend upon applications of electricity. An example of this will be found in the spectacle of the Galveston Flood; while in the thrilling pictures of "Fire Fighting," no actual fire is used, but the effects are obtained with electricity, steam, stained glass and electromechanical appliances. Such names as "Creation," "Hereafter," "Haunted Castle," "Submarine Diving" "Wireless Telegraphy," also suggest a variety of means by which electricity is to be brought into play to please or fascinate the multitude.

Electrical and Mechanical Engineering in the Exposition Plant.

By J. R. CRAVATH.

AT the Louisiana Purchase Exposition there will be of interest to engineers all the great electrical and mechanical exhibits coming under the Division of Exhibits and the application of mechanical and electrical engineering in the operation of the Exposition coming under the Division of Works. These two divisions overlap in so far as exhibit apparatus is used in the service of the Exposition. It is the purpose of the present article to summarize the work of the electrical and mechanical department of the Division of Works. The Division of Works builds and operates the Exposition, including the construction and operation of the necessary steam, electric and hydraulic machinery to properly serve the needs of the Exposition. This latter apparatus comes under the mechanical and electrical department of the Division of Works. All of the work in the Division of Works is in charge of Director Isaac S. Taylor. Mr. Henry Rustin was chief of the mechanical and electrical department until ill health compelled him to drop this work. His place was taken by Mr. E. B. Ellicott, city electrician of Chicago, who associated with him R. H. Moore, electrical engineer, and H. F. Smith, mechanical engineer.

SOURCES OF ENERGY.

Those having in charge the electric light and power service of the Exposition have had placed at their disposal three sources of energy: The Union Light & Power Company, of St. Louis, has agreed to deliver at the Exposition grounds, before the opening of the Exposition, 7,500 kw, in three-phase, 25-cycle, 6,600-volt current. In the Machinery Building the Exposition has a service plant of 8,000 kw, for which it contracted with the Westinghouse Electric & Manufacturing Company. This service plant was described in ELECTRICAL WORLD AND ENGINEER of January 23, 1903, and February 27, 1903. This plant also gives 25-cycle, 6,600-volt, three-phase current. In addition to this there will be in the Machinery Building exhibitors' apparatus, capable of supplying 8,000 kw in similar current for the service of the Exposition. The total amount of 6,600-volt, three-phase, 25-cycle current will, therefore, be about 23,500 kw. Besides this, exhibitors' apparatus is expected to furnish 2,400 kw in 550-volt direct current and 600 kw in 250-volt direct current. In the various buildings where necessary, rotary converters operated from the standard three-phase circuits of the Exposition are placed and will be used to supply 110-volt direct current for the use of exhibitors.

Both service and exhibit plants are to be supplied with steam from boilers in the Steam and Fuels Building. The distance that steam will have to be piped for some of the large units will be over 700 ft., and more than this for some of the smaller units. In the Steam and Fuels Building are sixteen 400-hp Babcock & Wilcox boilers equipped with Roney stokers.

The exhibit boiler plant will probably have 300 hp in Derr boilers, 550 hp in Clonbrock, 800 hp in Niclausse, 900 hp in Belleville, 3,200 hp in Heine, 7,200 hp in Cahall, and possibly 800 hp more. The rated boiler capacity for the entire building will, therefore, be about 19,350 hp. The Heine boilers will be equipped with Greene link grates, and the Cahall boilers with Aultman & Taylor chain grates.

The stacks for the boiler plant are all 90 ft. high and induced draft will be used throughout. The erection of buildings falls to the work of this division of the Exposition. Much of the work is being done by the Exposition company's own men, but steam piping contracts to the amount of $160,000 have been let in connection with the Exposition steam plant. The three concerns with which contracts have been made for steam piping are the Hanley Casey Company, Kroeschell Bros. and W. A. Pope. A detailed description of the Westinghouse service plant has already been given, as above mentioned.

CONDENSING PLANT.

Most of the large engines will be run condensing. The Westinghouse service plant is equipped with its own cooling towers. The exhibitors' service plant will take condensing water from the lagoons. An interesting engineering feature of the Exposition will be the fact that the Cascades, which is the name applied to the great artificial waterfall, which is to form the central feature of the Exposition panorama, will act, as at Paris, as a cooling tower for the condensing water used by the exhibitors' power plant. The condensers in the Machinery Building will discharge hot water into a tunnel, which runs 1,100 ft. from the Machinery Building to the suction of the Cascade pumps. Much of this tunnel is under the lagoon. From the Machinery Building to the lagoon a short distance away the water is taken through two 24-in. vitrified tile pipes. Under the lagoon the tunnel is 6 ft. by 6 ft., with board walls.

FIG. 21.—A NIGHT EFFECT NEAR ELECTRICITY BUILDING.

The intake for the condensers, which runs from the lagoon to the Machinery Building, is of 36-in. vitrified pipe. This pipe is 400 ft. long over all. Water runs through it by gravity to four cold wells in the Machinery Building, from which wells it is drawn by the condensers. Two of these cold wells are 8 ft. by 8 ft., and two are 14 ft. 8 in. by 14 ft. 8 in.

The Cascade pumping plant is to consist of three 2,000-hp Westinghouse induction motors running at 365 r.p.m., direct-connected to Worthington centrifugal pumps, each with 36-in. discharge and 40-in. suction. The water will probably be pumped over the Cascades at the rate of about 15,000 gallons per minute. The total fall is about 154 ft.

DISTRIBUTION FOR LIGHT AND POWER.

This is to be an exposition of "magnificent distances." The distribution of electric light and power will, therefore, be carried on along much the same lines as the distribution for electric light and

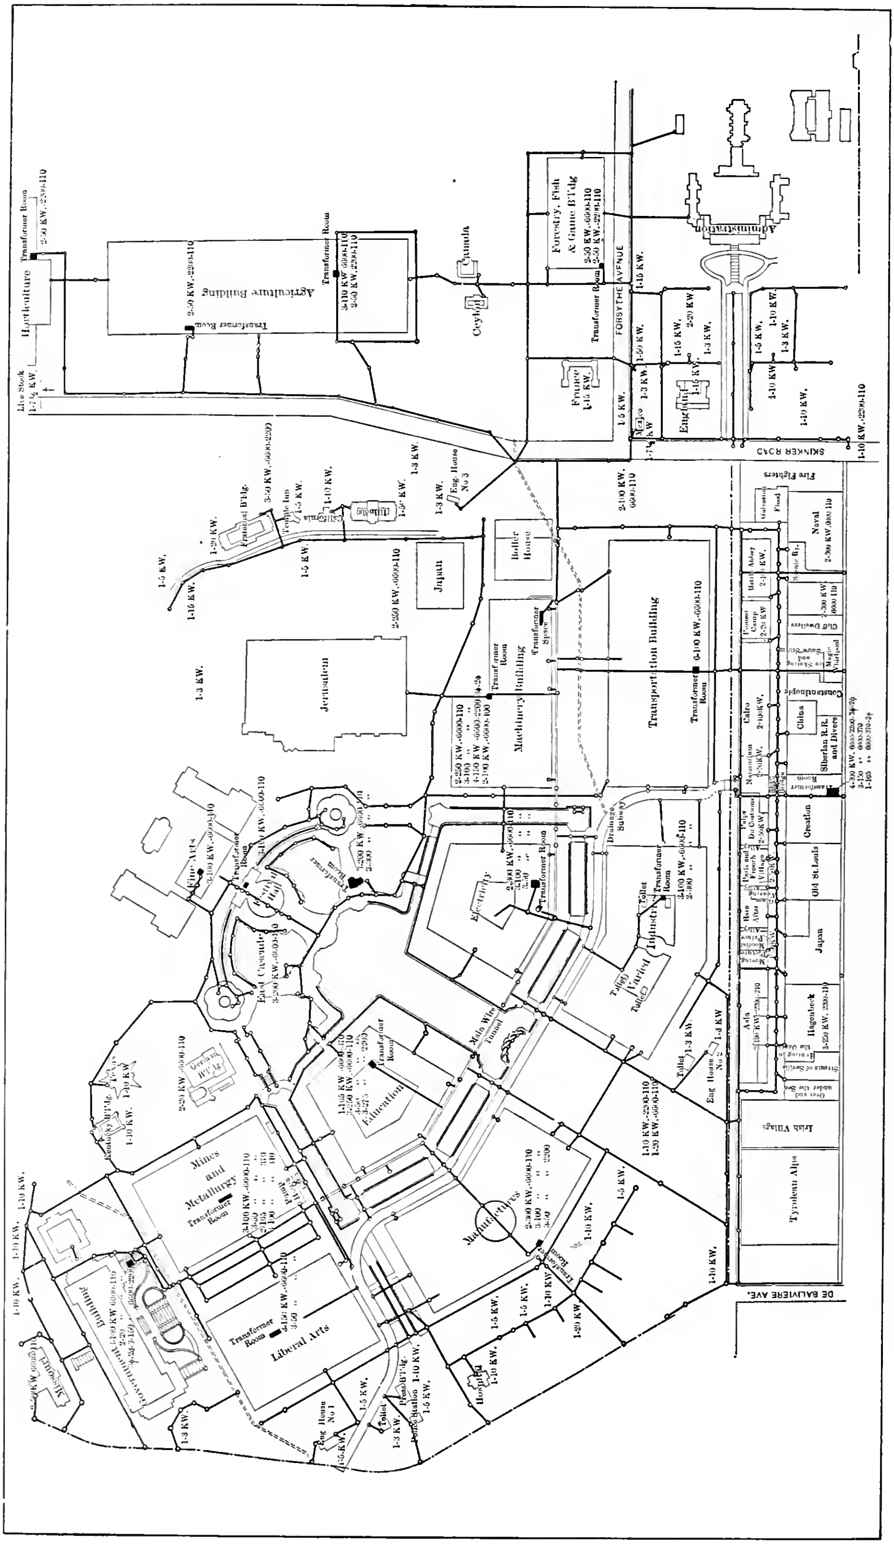

Fig. 22.—Ground Plan of the Louisiana Purchase Exposition.

Showing Distribution System with Location of Power Plants, Sub-Stations, Transformer Rooms and Output Capacity.

power in a large city. As said before, most of the current available is in the shape of 6,600-volt, 25-cycle, three-phase current. From a large switchboard in the west end of Machinery Building, through which switchboard all current used in the service of the exposition must pass, the distribution is by lead-covered cables in pump log ducts.

In each building will be a sub-station consisting of a transformer room and switchboard. If direct current is required, a rotary con verter will also be placed in the sub-station.

About 5,000 kw is to be used on the decorative lighting of the exterior of the buildings. Each of the large buildings will have a separate feeder supplying the transformers for the decorative lighting of that building. The decorative lighting will be run on a 400-volt, four-wire system of distribution. From the four-wire distri buting centers two-wire circuits, carrying about 1,300 watts each in 8-cp lamps, are run. Most of the wiring for decorative lighting is on knob and in tube. Open work has been wired with slow-burning weather-proof insulation on the wires, and concealed work has bee wired with rubber-covered wire.

The interior lighting of buildings by the Exposition is designed simply to be sufficient for patrol purposes. Additional lighting will be contracted and paid for by individual exhibitors, according to their needs. The lighting of building interiors is to be done by 50-cycle, alternating-current enclosed arcs. These arcs are to be 6.5 amp., run on circuits of about 3,500 volts maximum. The constant-current transformers for arc lighting are to be located in Machinery Building. About 1,200 kw is to be used in such arc lighting. This lighting will be run from alternating-current generators in the exhibitors' power plant. A limited amount of 110, 220 and 500-volt direct current will be available in each principal building. The three-phase alternating-current circuits for general commercial uses in each building, such as exhibitors' lights and motors, will be supplied by a feeder to each building run independently of the decorative lighting for that building.

It is the intention to use the current supplied by the Union Light & Power Company on the decorative lighting. The Union Light & Power Company's current is thus taken first to the main switchboard in Machinery Building over three feeders. Where these feeders enter the Fair grounds there is a terminal house, in which are located water rheostats, which will be employed for putting the decorative lighting load on gradually. This same plan was tried at the Pan-American Exposition at Buffalo with great success, both from the standpoint of the public and that of the operating engineers. The gradual bringing up of all the decorative Exposition lighting from darkness to a full brilliancy was one of the most popular and beautiful features of the Pan-American Exposition. This method of bringing on the load was also highly desirable from the power company's standpoint, as it gave the governors time to act and obviated strain on the apparatus.

The great switchboard extending entirely across the central bay in the west end of Machinery Building is designed for the control of all the 6,600-volt, three-phase current used on the Exposition grounds. It is a brick masonry structure supported upon timber work and occupying a height of two galleries. It consists mainly of feeder panels, as most of the generator panels will be located near the machines which they control. The four generators in the service plant have control panels in this switchboard. There are in all 17 feeder panels, four generator panels, three total load panels, three exciter panels, two incoming feeder panels from the Union Light & Power Circuits, and one rheostat panel for controlling the water rheostats employed in connection with the decorative lighting. This board has been built in a very thorough manner, as the handling of such high-pressure current would be inadvisable around anything in the way of a make-shift. It was designed by the staff of the Exhibition in association with the Westinghouse Electric & Manufacturing Company, and the actual construction of the board was under the direction of Mr. K. Nurian. The features of safety and quick handling have been carefully attended to and the board is in itself a worthy exhibit of some of the latest developments in this branch of electrical work.

During the last week or two a large proportion of the service above described has gone into successful operation, and as many of the pictures furnished show, the illumination of the buildings is attended by some very rich and beautiful effects. All the work in Machinery Hall has also been pushed vigorously and the large plant there has already taken shape. It will not be long before the equipment is all in full running order.

The World's Fair Machinery Display.

BY LIEUT. G. L. CARDEN, U. S. REVENUE SERVICE.

THE late President McKinley declared that expositions are the landmarks of progress, and these memorable words uttered so shortly before his death are strikingly emphasized by the opening on the 30th day of April, 1904, of the greatest Exposition the world has ever seen. This Exposition has for its historical motive the commemoration of the centenary of the purchase from France of the Louisiana territory, and because of its geographical fitness with relation to the acquired territory St. Louis was early selected as the logical site for the holding of the Exposition.

The World's Fair, of 1904, covers 1,240 acres. The World's Co-

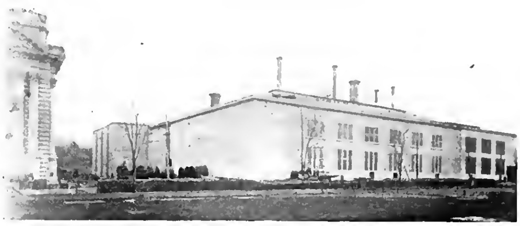

FIG. 23.—BOILER HOUSE.

lumbian Exposition at Chicago covered 636 acres. The exhibit buildings at Chicago embraced 82 acres of housed flooring. The main exhibit palaces at St. Louis have under roof 128 acres, and in addition more than 100 acres have been set apart for outside exhibits. With the foregoing facts in mind let us consider the machinery display of the Exposition.

The Machinery Department at St. Louis embraces exhibits collected from the masters in trade. This is the policy which was inaugurated from the first by Mr. Thomas M. Moore, chief of the Department of Machinery, and it has been successfully carried forward

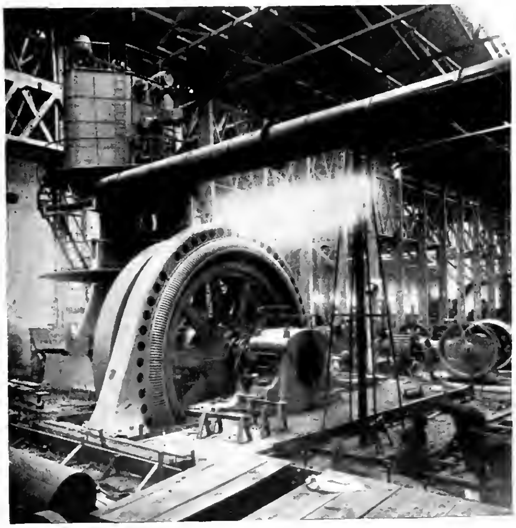

FIG. 24.—ALLIS-CHALMERS ENGINE, MACHINERY HALL.

to a final issue. The floor area in the Machinery Department embraces something like nine acres, and nearly a year ago this total floor area was applied for many times over. With Mr. Moore the idea has been uppermost that a duty existed with reference to both the trade and the public, and that a broader policy should be pursued than the mere filling of the floor space with a confused mass of odds and ends of machinery. The idea has been to secure only the latest and the most up-to-date items, and with this object in view only the leaders have been encouraged to make displays. The Machinery Hall is a superb structure measuring 1,000 ft in length, and for at least half of this distance its width is 500 ft. In the eastern half of the building is installed the great power plant of the World's Fair, involving something like 45,000 hp. In the western half of the building is installed machinery for making machinery. In close proximity to the eastern end of Machinery Hall is the Steam, Gas and Fuels Building. This is a steel, fire-proof structure measuring 320 ft. in length by 300 ft. in width, and comprising within its enclosure all the steam and gas generating forces for the great power plant. For the first time in Exposition history, an exhibit feature has been made of this adjunct of the power assemblage, and at St. Louis the visitor will find boilers of the latest types from different countries of the world all working in unison. All stoking will be mechanically operated, and it is aimed to have the building as free from dust and dirt as modern mechanical appliances can make it.

In the summer of 1902 the writer, acting under the instructions of the chief of the Machinery Department, began a systematic inspection among the most distinguished of the great iron and steel and machinery houses of Europe for the purpose of collecting items of a special interest for service in connection with the power plant of the Exposition. More than 350 plants were visited in Germany, and the total number of plants visited or directly communicated with throughout Europe totaled more than 1,000. As fast as offerings were secured of desirable topics the facts were reported to St. Louis, and the acceptance or rejection of the same rested with the chief of the machinery display. So keen were the European builders of machinery and accessories to make exhibits at St. Louis that it is the firm belief of the writer that had it been necessary practically all the horsepower that might have been required could have been secured from the Old World. As the situation now exists, the great power plant at St. Louis will embrace some superb engines, boilers and accessories, which have originated from abroad, and it will be especially interesting to observe that in the items which come from the Old World their distinguishing features will be in economical attachments and economical devices. The German exhibits will show the superlative in what has been attained in economics, and the writer cannot refrain from remarking that the man is very blind indeed who can travel to-day among 350 German iron, steel and machinery works without seeing much to learn. It must not be forgotten that Germany's position in machinery development has practically been taken within the past decade, and so great has been this advance that to-day the transatlantic ocean record is held by a Stettin-built ship, the *Deutschland*. When this great vessel made her record run to the eastward, a record which stands to-day, the story is told that on entering the first English port she hoisted to her mast heads a great band of canvas stretching between her foremast head and mainmast head, and on this big banner of canvas in huge black letters, which could be read with the naked eye more than a mile distant, was this inscription: "Made in Germany." The German exhibits at St. Louis in the Machinery Department will call for the most careful study on the part of the visitor, and so keen have been the German manufacturers to make displays that it is not at all uncertain that the Machinery Hall could, if desired, have been filled with German exhibits alone.

But for the superlative in the high-speed steam engine line, the visitor will naturally turn to machines bearing British stamps, for it is a fact that in the high-speed steam engine line the British lead in the world to-day. This statement, it must be understood, applies to engines of large power; and despite the magnificent showing of engines at the Dusseldorf Exposition there was no high-speed steam engine there comparable to the engines of large power such as are turned out by, for example, Behlis, of Birmingham; W. H. Allen & Co., of Bedford, England, or Willans & Robinson, of Rugby, England. In the machinery display at St. Louis there will be found a beautiful engine of the last-named make furnished through the medium of the American builders of this machine, the C. H. Bradley, Jr., Co., Pittsburg, Pa.

FIG. 25.—GENERAL VIEW OF MACHINERY HALL.

In his inspection of the various shops abroad, the writer found the most marked difference between home and foreign shop practices. At the great Krupp works at Essen car wheels were observed being loaded onto trucks by hand. In fact, there appeared to be as a general rule a lack of labor-saving devices at least to the extent with which one is familiar with such equipment in American shops. Take, for example, the Curtis system of overhead trams. Although one does find tram systems in some German shops, still the writer found no such superb installation schemes as one observes, for example, a the Illinois Steel Works shops near Chicago. In the Machinery Hall display there will be found an exhibit of this overhead system of tramway runs. In one of the first boiler shops in all Germany the writer observed that the work was carried on for the most part by hand. It seemed almost incredible, especially when one considers the possibilities afforded to-day by pneumatic tools. In the machinery tool end of Machinery Hall there will be a very fine display of pneumatic tools.

Ten years ago one might have traveled up and down the Rhenish provinces and in all the principal German shops one would have found for the most part English machine tools. To-day all this is changed, and in lieu of English tools one finds for the most part German stock tools, but one also finds almost invariably, in all the leading German plants, a small group of American machine tools for the high-grade work. It is a silent tribute to the excellence of our output.

Among the various makes of American machine tools which the writer observed abroad those of the Niles firm were very much in evidence, and this house will make a diplay at St. Louis which will excel anything of the kind ever heretofore attempted. Some of these Niles tools for the Machinery Hall exhibit will weigh not less than 300 tons. There will be, for example, a huge universal radial drilling machine, capable of drilling to the center of a 20-ft. circle. Then, there will be a great horizontal boring, drilling and milling machine, with adjustments admitting of test readings in thousandths of an inch. All these Niles tools will be motor-driven, and in this connection the writer is reminded of a remark recently made to him by a leading German manufacturer, which was in effect that the presence of a belt on a machine tool to-day was an occasion for an apology. The Niles firm will also show a massive steam hammer, its ram and attached parts weighing 24,000 pounds. Then there will be a 120-in. engine lathe and an enormous plate-bending machine, capable of bending a plate 20 ft. long by one inch thick, or its equivalent, and as a further contribution there will be found an extra heavy planer designed for planing armor plate and other work requiring the greatest power. The shipping weight of this last machine, alone, with a 35-ft. table, is 300 tons.

Space will not permit in this article to enumerate all the topics in Machinery Hall, but with reference to the boiler display it can be said roughly that the exhibit will include generators from practically all the distinguished makers of both the Old and New World. Among the names are Derr, Belleville, Conti, Niclausse, Aultman-Taylor, Babcock & Wilcox, Cahall, Clonbrock, Hohenstein, Geary and others. As an idea of what work is demanded of the boilers, it may be interesting to know that when the generators are working at full load they will evaporate 700,000 pounds of water per hour. This means that 350 tons of water will be hourly changed into steam, pass through the engines, return to the form of water by passing through condensers, and then be re-delivered to the boilers to be again transformed into live steam. The steam from the boilers before reaching the main engine must be conveyed through pipe lines having lengths some instances of 400 ft. A tunnel 7 ft. broad and 8 ft. deep will receive the pipes, one of which is 18 in. in diameter, another 16 in., and none less than 10 in.

In taking note of the handling of material in foreign shops, the writer found electric cranes in general use, but he found no crane service quite as rapid as, or more efficient, than that afforded by the best American cranes. In Machinery Hall there will be a number of electric traveling cranes, and one of the most interesting of the lot will be a superb Shaw crane. As is well understood, such cranes have played a most important part in the development of modern heavy manufacturing, and the makers of the Shaw crane were practically the first to utilize the three-motor service. This type has been in use in the United States ever since 1889. It is an interesting fact that the greatest difficulty is not met in designing a crane that will hoist a load, but in providing means for lowering it rapidly and at the same time keeping it under perfect control. This is accomplished by means of an automatic load brake. Different types are used, but the essential feature of all is that the weight of the load applies the brake, and running the motor in the lowering direction releases it, either entirely or sufficiently, so that it slips and allows the load to descend. A magnetic brake is also provided.

All the principal electric manufacturing houses in America have been called upon to do service in connection with the power plant. The total amount of electric energy required is about 45,000 hp. Of this amount about 32,000 hp will be delivered in alternating current at 25 cycles. This energy is supplied in varying amounts by plants all installed in the western division of Machinery Hall. One of the largest pieces of electric apparatus in this installation is a 3,500-kw 6,600 volts, 25 cycles, three-phase, engine type generator running at 75 r.p.m., built by the Bullock Electric Manufacturing Company, of Cincinnati, Ohio. This is direct-connected to a 5,500-hp single-crank compound Allis-Chalmers engine, the total height of which, including its base, is 54 ft. The total weight of engine complete and the generator is over 500 tons, the generator alone without the shaft weighing 150 tons. The overall dimensions of the floor space taken up by this generating set are approximately 35 by 45 ft. Both in the electrical and mechanical design of this machine many novel and interesting features have been embodied. The yoke is cast in four sections, securely held together by body-bound bolts; the outside diameter of the yoke is 27 ft., while its overall dimension is 33 ft., the total weight of the casting being 58,000 pounds. This machine will attract much attention.

The engine cylinders measure 44 in. for the high-pressure cylinder

FIG. 26.—GENERAL VIEW IN MACHINERY BUILDING.

and 94 in. for the low-pressure cylinder. The stroke of both is 60 in. The wheel is 25 ft. in diameter and weighs 300,000 pounds. The speed of the engine is 75 r.p.m.

Nearly all the electric generators in connection with the engines for the Intramural Railway are furnished by the Crocker-Wheeler Company, as already shown in these pages. This Intramural Railway is a double-track trolley standard gauge road some seven miles in length and equipped throughout with cars and other accessories on an exhibit basis. There is one unit of 900-kw capacity running at 110 r.p.m.; a 600-kw generator running at 85 r.p.m.; and three units of 500-kw capacity, one with a speed of 100 r.p.m., and two at a speed of 135 r.p.m. There is a seventh unit of 400-kw capacity, which will be operated at 150 r.p.m.

The Westinghouse Company is taking care of one installation of 12,000 hp, while from the General Electric Company comes, in addition to other items, a Curtis turbine of 5,000-kw capacity. This latter unit will probably be one of the most instructive in all the assemblage of great engines.

At the Paris Exposition of 1900 the pumping requirements demanded 4,500 gallons of water per minute. At St. Louis three enormous centrifugal pumps will force up, and send rolling down the face of Art Hill 90,000 gallons of water per minute. The Cascade pumps for the Exposition are supplied by the Worthington Company and the stipulations in connection with the same set forth that each of the three pumps must be capable for forcing 30,000 gallons of water per minute against a head of 158 ft. As a matter of fact, these pumps are designed for an overload of 25 per cent., which brings their maximum capacity up to 115,000 gallons of water per minute. Large volumes of water have been handled to a lesser elevation, but no such amount of water has ever been artificially moved to such a height as is required in the case of the Cascades of this Exposition.

Electrical Exhibitors at St. Louis.

We give below a list of electrical exhibitors at the St. Louis Exposition, furnished by Prof. W. E. Goldsborough, in charge of that department of the work. It will be noted that the lists for foreign countries have not been extended in full.

Adams-Bagnall Electric Company, Cleveland; A. S. Aloe, St. Louis; American Carbon & Battery Company, St. Louis; American Circular Loom Company, Chelsea, Mass.; American Electric Fuse Company, Chicago; American Electrical Heater Company, Detroit; American Electrical Novelty & Manufacturing Company, New York; American School of Correspondence, Chicago; American Telephone & Telegraph Company, Boston; the American Watchman's Time Detector Company, New York; American Watchman's Time Detector Company, Cleveland; Bion J. Arnold, Chicago; Association of Edison Illuminating Companies, Chicago; Martin Armstrong, St. Louis; Atlanta Utility Works, East Point, Ga.; the Automatic Electric Company, Chicago; Automatic Fire Alarm Company, New York City; Argentine Republic.

Baird Manufacturing Company, Chicago; Carl Bajohr, St. Louis; Bario Vacuum Company, New York; M. V. Barlow, Chicago; W. M. Bashlin, Warren, Pa.; Mrs. Alexander Baumgart, New York City; Benjamin Electric Manufacturing Company, Chicago; The Bristol Company, Waterbury, Conn.; The Browning Company, Milwaukee; The Bryant Electric Company, Bridgeport, Conn.; Bullock Electric Manufacturing Company, Cincinnati; Burdett-Rowntree Manufacturing Company, Chicago; Burnham-Williams & Co., Philadelphia.

H. B. Camp Company, Chicago; Carbondale Machine Company, Carbondale; Cassidy & Son Manufacturing Company, New York; Carman Projector & Specialty Company, Chicago; Central Telephone & Electric Company, St. Louis; Chicago Fuse Wire & Manufacturing Company, Chicago; Colonial Sign Company, Akron, Ohio; Chicago X-Ray Company, Chicago; James Clark, Jr., & Co., Louisville; A. Frederick Collins, New York; Commercial Electric Company, Indianapolis; Controller Company of America, St. Louis; Cooper Hewitt Electric Company, New York; Crocker-Wheeler Company, Ampere, N. J.

The Dayton Autoelectric Company, New York City; De Forest Wireless Telegraph Company, New York; Patrick B. Delany, South Orange, N. J.; The Dayton Electrical Manufacturing Company, Dayton, Ohio; Dialt Motor Company, Philadelphia; Dicke Tool Company, Downers' Grove, Ill.; Dodd & Struthers, Des Moines, Iowa; S. R. Dresser, Bradford, Pa.

Economical Electric Lamp Company, New York; Thomas A. Edison, Orange, N. J.; Electra Water Purifier Company, St. Louis; Electric Circulator Company, Chicago; Electric Contract Company, New York; Electric Controller & Supply Company, Cleveland, Ohio; Electric Railway Equipment Company, Cincinnati; Electric Storage Battery Company, Philadelphia; Eureka Tempered Copper Works, North East, Pa.; Electrical World and Engineer.

Faller Automatic Telephone Exchange Company, New York; Federal Electric Company, Chicago; C. J. Field, New York; Fort Wayne Electric Works, Fort Wayne, Ind.; France.

Germany; The Gardner Electric Drill & Machinery Company, Cleveland; General Electric Company, Schenectady, New York; Gervais Manufacturing Company, Edgewater, N. J.; G. M. Gest, Cincinnati; W. E. Goldsborough, La Fayette, Ind.; Gould Coupler Company, New York; Gould Storage Battery Company, Depew, N. Y.; Gray National Telautograph Company, New York; Gray Telephone Pay Station Company, Hartford, Conn.; A. Grothwell, San Francisco, Cal.

C. F. Hall, Chicago; Robert E. Haward, Kansas City, Mo.; The Heinze Electric Company, Lowell, Mass.; Hellesens, Enke & V. Ludvigsen, Copenhagen, Denmark; Hinton & Tarkington, Hot Springs, Ark.; Holmes, Booth & Haydens Company, New York; Holophane Glass Company, New York; C. W. Hunt, West New Brighton, New York; Miller Reese Hutchison, New York City; Hutchison Acoustic Company, New York.

Italy; Indiana Novelty Company, Muncie, Ind.; International Acheson Graphite Company, Niagara Falls, New York; J. Van Inwagen, Momence, Ill.

The Jackson Electric Drill & Supply Company, Denver, Colo.; The Jandus Electric Company, Cleveland.

Charles Kaestner & Co., Chicago; Kellogg Switchboard & Supply Company, Chicago; Kester Electrical Manufacturing Company, Chicago; Keystone Electrical Instrument Company, Philadelphia; The Kny-Scheerer Company, New York; H. E. King, Chicago; D. A. Kusel Telephone & Electric Manufacturing Company, St. Louis.

The Leclanche Battery Company, New York; Lincoln Electric Company, Cleveland; Lionel Manufacturing Company, New York; Locke Insulator Manufacturing Company, Victor, N. Y.

Mexico; McGraw Publishing Company, New York; McRoy Clay Works, Chicago; Marshall-Sanders Company, Boston; W. E. Matthews & Brother, St. Louis; The Miller Anchor Company, Norwalk, Ohio; Mystic Electric Gas Lighter Company, New York; Moloney Electric Company, St. Louis.

National Carbon Company, Cleveland; National Battery Company, New York; National Cash Register Company, Dayton, Ohio; National Electric Company, Milwaukee, Wis.; Nernst Lamp Company, Pittsburg; National Clock Works, St. Louis; Northern Electrical Manufacturing Company, Madison, Wis.; Norton Emery Wheel Company, Worcester, Mass.; Nungesser Electric Battery Company, Cleveland.

The Organ Power Company, Hartford, Conn.

Pawling & Harnischfeger, Milwaukee, Wis.; The Peerless Electric Company, Warren, Ohio; Perkins Electric Switch Manufacturing Company, Bridgeport, Conn.; The Phelps Company, Detroit, Mich.; Walter P. Phillips, Bridgeport, Conn.; Pittsburg Blue Print Company, Pittsburg; Pneumatic Signal Company, Rochester, N. Y.; Postal Telegraph Cable Company, St. Louis; Printing Telegraph News Company, St. Louis; Prometheus Electric Company, New York City; Purdue Research Laboratory, La Fayette, Ind.; Portugal.

Queen & Co., Philadelphia; F. Herrero y Ruix, Albacete, Spain.

Reynolds Electric Flasher Manufacturing Company, Chicago; The Robbins & Myers Company, Springfield, Ohio; Chicago Röntgen X-Ray Laboratory, Chicago; Roth Brothers & Co., Inc., Chicago.

St. Louis Brass Manufacturing Company, St. Louis.

The Safety Insulated Wire & Cable Company, New York; Sawyer-Man Electric Company, New York; W. Scheidel & Co., Chicago; M. Shearer, Akron, Ohio; Shedd Electric & Manufacturing Company, New York; Standard Underground Cable Company, Pittsburg; Standard Water Purifying Company, Cleveland; Sterling Electric Company, New York; Sterling Electric Motor Company, Dayton, Ohio; S. W. Stratton, Washington, D. C.; William F. Stilz & Co., Philadelphia; Sumter Telephone Manufacturing Company, Sumter, S. C.

Telephone Hygienic Company, Los Angeles, Cal.; C. H. Thordarson, Chicago; C. J. Toerring Company, Philadelphia; Triumph Electric Company, Cincinnati, Ohio.

Underwriters' Laboratories, Chicago; U. S. Incandescent Lamp Company, St. Louis; United States Electric Signal Company, West Newton, Mass.

E. C. Van Nort Electric Company, St. Louis.

Wagner Electric Manufacturing Company, St. Louis; R. V. Wagner & Co., Chicago; Waite & Bartlett, New York; Warren Ball-Bearing Fixture Company, New York; Warren Electric & Specialty Company, Warren, Ohio; Warren Electric Manufacturing Company, Sandusky, Ohio; B. F. Wasson, Clinton, Ill.; Western Electric Company, Chicago; Wesco Supply Company, St. Louis; *Western Electrician*, Chicago; Western Union Telegraph Company, St. Louis; Weston Electrical Instrument Company, Newark, N. J.; Westinghouse Electric & Manufacturing Company, Pittsburg; Wheel Truing Brake Shoe Company, Detroit, Mich.; Windsor & Kenfield Publishing Company, Chicago; Wireless Railway Company, Philadelphia; Westinghouse Traction Brake Co., New York; The Wyckoff Pipe & Creosoting Company, Stamford, Conn.

Charles E. Yetman, New York.

A Trolley Line Up Mount Vesuvius.

The famous volcano at Mount Vesuvius has hitherto been quite difficult of access from Naples, although when once the foot of the mountain was attained, the cable road has been there, beginning at the base of the lava cone 2,450 ft. above the sea and running up to a height of 3,700 ft. in the vicinity of the old crater and about 360 ft. below the new one. One can have a "hot time" there, and until recently one had a "hot time" getting there. But the great tourist firm of Messrs. Cook, who own the cable road, have now installed a very interesting trolley line from Resina on the outskirts of Naples right to the foot of the cableway, and the distance of $4\frac{1}{2}$ miles is covered in 48 minutes, with all stops included.

The grades between Resina and San Vito do not exceed 8 per cent. About the same grades are found between the Government Observatory and the cable railway. It was determined, therefore, to

FIG. 1.—GENERAL VIEW OF MT. VESUVIUS; ELECTRIC RAILWAY IN THE FOREGROUND.

operate both of these divisions by an electric railway. For the section between the power station and the observatory a rack road was chosen, as that division includes grades as high as 25 per cent. On this division the motor car of the electric railway is hauled by an electically-driven rack locomotive. The Vesuvius Railway, as now completed, has a gauge of 1 meter and is divided into three sections, having a total length of 4.5 miles. The first section is an electric railway starting at Pugliano (the upper part of Resina), and extending 1.0 miles to the power house and car house. The minimum curve radius is 164 ft. The second section, as stated, is a rack road, and runs from the power house to the observatory. Its length is about 1 mile and its highest point nearly 1,950 ft. above the sea. The third section is an ordinary electric railway, similar to the first, and is 1.62 miles long. The roadbed in general is built in accordance with the practice adopted on the later Swiss mountain railways.

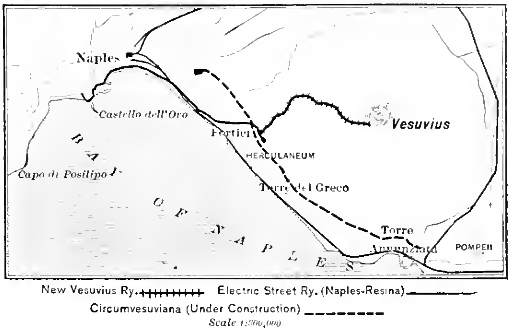

FIG. 2.—MAP OF MT. VESUVIUS ELECTRIC RAILWAY LINE.

From Pugliano the line traverses a very fertile agricultural district, and just before reaching the rack road passes through a number of petrified lava streams. The first station, San Vito, is in the middle of the garden district, about .87 mile from the beginning of the line. From this point the railway runs for 1.02 miles in an almost straight line to the rack road. The lower portion of the latter road passes through inhabited territory, but soon enters a large forest, from which it does not emerge until it reaches the observatory. The observatory railway station lies very near the large hotel which has been built at this point by Messrs. Cook. There is also close to the station a little chapel and park. From this station the line is again of the ordinary electric railway construction, and traverses a distance of approximately 1.62 miles before reaching the lower station of the old cable railway.

The track construction of the electric line consists of rails 3.94 in.

FIG. 3.—BUILDING THE RACK RAIL DIVISION.

high, weighing about 40 pounds per yard. The rack rails are laid on 11-ft. 3-in. sections, while the outside rails are 33 ft. 9 in. long. The rails on the rack road and the curves on the other divisions are anchored by means of iron tie plates. On straight track of the electric railway divisions the joints are furnished with the usual base plates as well as angle plates. Oak ties are used throughout rather than metal ones, as they can be replaced more quickly in case of lava overflows, and because the Strub rack system operates equally well with metal or wooden ties. These ties are 6 ft. long, 6.3 in. to 7 in. wide and 4.73 in. to 5.52 in. high. Plastic bonds are used for bonding in the rail return except at special work, where wire bonds are used.

To make possible a 35-minute headway turnouts have been built at each end of the rack division. The present equipment consists of three motor cars and two rack locomotives. The cars have single trucks of 6.2 ft. wheel base, and weigh 4,200 pounds (8,400 kg.) each, without motors. The motors are of the direct-current series type, and are built somewhat larger than would otherwise be required, on account of the heavy grades and warm climate. All cars are built in three sections, each of which has a separate side door. The seating capacity is eight passengers per section, with additional room for six passengers on the platform. The sides of the car are cut off half-way to the roof, but in stormy weather the openings may be closed by water-proof curtains. The cars are equipped with bow trolleys. Owing to the severe grades each car is furnished with two independent sets of braking apparatus. The first consists of a powerful spindle brake, furnished with eight brake shoes, which can be operated from either platform. The second consists of an electric short-circuiting brake combined with an electromagnetic track brake. To overcome slippery rails two sanders are supplied at each end of the car. When the motor cars are used on the rack division they are pushed by the electric locomotive, so that no brakes are required; the rack locomotive is equipped with four independent brakes, each of which is capable of controlling both locomotive and car.

The rack locomotive weighs about 5,200 pounds and is capable of running at about 5 miles per hour when propelling a load of 5,500 pounds on a 25 per cent. grade. It is equipped with two 80-hp shunt-wound motors, which run at 650 r.p.m. to 700 r.p.m., and operate the rack-driving wheels through gearing. The rack wheels are made of crucible steel and weigh about 40 pounds each. As the motors are shunt-wound, current is returned to the line when the locomotive is running down grade.

The power plant is furnished with two 67.5-kw, 550-volt, direct-current generators, running at 700 r p.m., and operated by belting from the fly-wheel of two 100-hp, 160-r.p.m. gas engines, using producer gas. The generators may be connected in parallel to a Tudor storage battery having 300 elements and a capacity of 256 amp.-hours. These generators are wired according to the C. E. L. Brown system, which enables them to deliver current to the storage battery without the use of a booster. The full-load efficiency of each generator is 92 per cent. and the half-load efficiency 89 per cent. There are two gas producers, and as each is of 200-hp capacity only one is used at a time. There are also two boilers for these producers, one of which may also be held in reserve. The gas engines are started by compressed air, but can also be started by supplying the generators with battery current and momentarily operating the latter as motors. The power transmission line is divided into two sections by a section insulator, these divisions being respectively that from the power station to Pugliano, and from the power station to the cable railway. The third circuit leaving the switchboard was intended originally to be a feeder for the power house cable railway division or to furnish current for the electric motor which is to operate the cable railway. It has been found, however, that this feeder is unnecessary at present.

A circuit-breaker has been placed at the upper end of the rack railway near the observatory, dividing the power house cable railway section into two parts. In case of an eruption it will be possible, therefore, to cut off all current from the electric railway division between the observatory and the cable railway. The power circuits are protected by Wurts lightning arresters, which are mounted on poles along the line at intervals of about .6 mile. The lightning arresters are grounded through the rails. In addition to the power wires there are two telephone wires and one telegraph wire, used for dispatching and other purposes. All of the electrical apparatus throughout the system was furnished by Brown, Boveri & Co., of Baden. The general plan was that of Mr. E. Strub, of Zurich, Switzerland.

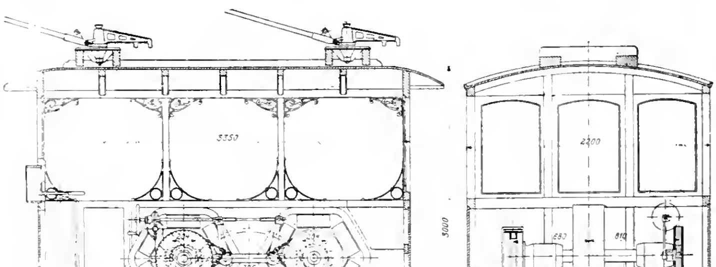

FIG. 4.—SECTION VIEWS OF ELECTRICALLY-DRIVEN RACK LOCOMOTIVE.

A Convenient and Economical Electrical Method for Determining Mechanical Torque.

By A. S. McAllister.

A LITTLE experience with the well-known mechanical and electrical methods for determining torque convinces one that the latter method is far preferable to the former with reference to ease of adjustment, flexibility of operation and reliability of results. For ascertaining the output from either mechanical or electrical motors, perhaps, the most familiar method is one which involves the use of a direct-current generator, of which the sum of the input and transmission losses is taken as the value of the output desired. The input to the direct-current generator is found as the sum of its output and its internal losses. In order to determine the internal losses of the generator, it is necessary to find the value of the individual iron, friction and copper losses. When the resistances of the separate circuits of the generator and the currents flowing therethrough are known, the copper losses may readily be calculated. The armature iron loss varies both with the speed and the density of magnetism. That the effect of any change in the latter may be

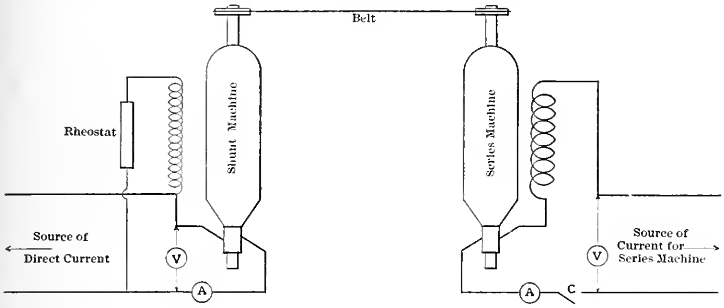

FIG. 1.—DIAGRAM OF TESTING CIRCUITS.

eliminated, it is usual to operate the generator as a shunt-wound machine with constant field excitation and with the armature brushes at the mechanical neutral point, under which conditions the iron loss will vary at a rate but slightly greater than the first power of the speed, and, where the nature of the test so dictates, the value may accurately be determined throughout any desired range of speed.

In cases where the load generator and the driving motor are constructed for the same e.m.f. and capacity, the output from the generator may be fed back into the supply line, the test thereby using only that amount of energy necessary to overcome the losses of the two machines. In these latter cases the individual losses of each machine are calculated as formerly and each is subject to the same errors as before, but the sum of the losses, being directly measured, is accurately determined and may be used as a check on the separate losses.

The method given below combines the convenience and economy of the "loading back" method, is subject to a less number of sources of errors and is applicable to all types of motors, either direct or alternating current, which may possess either the series or shunt motor characteristics, and in many cases it may with equally desirable results be applied to the testing of either mechanical or electrical motors.

The circuit diagram of Fig. 1 will serve to make clear the method of connecting the apparatus for the test and may be used to explain the theory upon which the test depends. In Fig. 1 the load generator is shown as a constant-potential, shunt-wound, direct-current machine, while the driving motor, as shown, is a series-wound machine, and may be of either the direct or alternating-current type. It is desired to find the torque of the series machine at various speeds. If the shunt machine be operated as a motor—being belted to the series machine which is run, with circuit switch C open, at a speed somewhat below that at which the value of the torque is desired to be obtained—it will require a certain armature current, I_0, at a certain impressed e.m.f., E. If now the switch, C, in the circuit to the series machine, be closed, the shunt machine will be driven at an increased speed and will require an armature current smaller than before—perhaps of negative value—due to the accelerating torque transmitted to the belt, and, if the e.m.f., E, and the field current of the shunt machine, remain constant, the value of the torque excited by the series machine, expressed in equivalent watts per revolution per minute, will be:

$$T = \frac{(I_o - I_L)\,E}{S},$$

where I_o is amp. taken by armature of shunt machine with switch, C, open;

I_L is amp. taken by armature of shunt machine with switch, C, closed;

and S is the "synchronous" speed of the set, as determined by the relation of the e.m.f. and field strength of the shunt machine.

The equation above expresses the value of the torque by which the series machine assists the shunt-wound machine, and gives the true value of the torque which the series machine delivers to its own shaft.

The convenience of this method in comparison with one which uses the shunt machine as a generator will be appreciated when it is considered that no account need be taken of the internal losses or of the output of the machine and that the field current of the shunt machine and therewith the speed of the set may be adjusted to any desired value for each determination of torque without affecting the results. The economy of the method is due to the fact that the set dissipates only that amount of energy represented by the losses of the two machines, all excess of power being returned through the constant potential supply circuit by means of the current, produced by the generator action of the shunt machine.

The accuracy of the method depends upon the following facts: A direct-current motor runs at a speed such as to generate an e.m.f. less than the impressed by an amount sufficient to force through the resistance of its armature a current of a value such that its product with the field magnetism gives the torque demanded at its shaft. With constant field magnetism the electrical torque of a direct-current machine, operated as either a motor or a generator, is given by the expression:

$$T = \frac{I\,E}{S},$$

where I is the armature current,

E is the impressed e.m.f.,

and S is that speed at which the counter e.m.f. of rotation of the armature windings in the field magnetism equals the impressed e.m.f.; that is, the "synchronous" speed as used above.

If Wo = watts output (electrical),

R = resistance of armature,

$r.p.m.$ = actual speed of armature,

then $T = \dfrac{Wo}{r.p.m.} = \dfrac{I\,E - I^2R}{r.p.m.} = \dfrac{I\,(E - I\,R)}{r.p.m.} = \dfrac{I\,Ec}{r.p.m.}$, where Ec is the counter e.m.f. of rotation. But $\dfrac{Ec}{r.p.m.} = \dfrac{E}{S}$ for constant field strength; hence, $T = \dfrac{I\,E}{S}$, as given above.

Since for a certain impressed e.m.f. S has a definite fixed value for each adjustment of field strength, with constant field magnetism, the internal electrical torque of the shunt machine varies directly with the armature current, and any change in the value of this current serves at once as a measure of the change in torque exerted by the shunt machine, quite independent of all other conditions.

It remains now to show why the change in torque of the shunt machine may be used to determine the torque exerted by the driving motor. The torque delivered to the shaft of the series motor is less than the internal electrical torque of the shunt machine by that necessary to overcome the iron and friction losses of the shunt machine and the transmission losses in the belt. Since the belt and friction losses vary directly with the speed, it will be evident that the counter torque due thereto will be constant. For constant field magnetism, the armature hysteresis loss varies as the first power, and the eddy current loss as the square, of the speed. Since in comparison with the other loss. that due to the eddy currents is relatively small, the sum of the iron, friction and transmission losses varies at a rate inappreciably greater than the first power of the speed and the torque necessary to overcome these losses may, for practical purposes, be taken as being independent of the slight change in speed. The change in the internal electrical torque of the shunt machine, when switch C, of Fig. 1, is closed, gives at once the value of the torque delivered to its shaft by the series motor.

The method outlined above may be used to determine the torque exerted by a machine when such torque is much less than that necessary to drive a generator of any capacity whatsoever and is, therefore, especially advantageous for tests where it is desired to find the torque, at high speeds of machines possessing series motor characteristics.

In Fig. 1 is shown a series-wound driving motor, but it will be evident that the change in torque, as given by the variation of the current taken by the shunt machine, may be produced by any type of motor. A little consideration will show that since, at any given speed, the torque exerted by the shunt machine of Fig. 1 may be adjusted throughout any desired range by use of the field rheostat, the method may conveniently be applied to motors possessing practically constant load speed characteristics, such as those of the direct-current, shunt-wound type or of the alternating-current induction type, and that alternating-current synchronous motors may be similarly tested, if after adjustment of the load on the synchronous motor by means of the rheostat in the field circuit of the shunt machine the supply of electric power be cut off from the synchronous machine in order to obtain the change in torque excited by the shunt machine.

Annual Report of the General Electric Company.

The reports of the General Electric Company for the year ending January 31, 1904, have just been issued. The financial condition is summarized in the report of President Coffin, which shows, after writing off $553,733 from patent account and $2,027,841 from factory plants and machinery a profit, less $76,007 interest on debentures of $7,789,369. From this is deducted a debit to profit and loss of $1,470,098 in writing off patents, etc., of Stanley Electric Manufacturing Company, the balance due on turbine patents, etc., making a net of $6,319,270. There was paid in dividends during the year a sum of $4,482,701, which deducted from the $10,801,972, representing last year's net profits, and the 1902 surplus of $4,482,972 left a surplus on January 31 of $7,293,688. Mr. Coffin in noting the fact that the percentage of profit was smaller in 1902 gives as reasons the disturbed financial conditions, the increased cost of copper, higher priced and less effective labor, lower selling prices and the expense of developing the steam turbine.

First Vice-President Griffin gives an interesting statement as to the business done. The total amount billed to customers reached the impressive sum of $41,699,617, as compared with $36,685,598 in 1902-3, although the orders received, due to lower prices, were $39,060,038, as compared with $30,944,454, showing that the company by increased capacity had been able to catch up with its orders. The gigantic output included about 900,000 hp of generators, rotaries and turbines; more than 7,000 railway motors aggregating over 300,000-hp capacity; transformers of over 650,000-hp capacity; more than 15,000 alternating and direct-current motors, aggregating over 200,000 hp; more than 75,000 arc lamps and 110,000 meters. General Griffin points with deserved pride to the brilliant success of the Manhattan Elevated equipment carrying over 1,000,000 passengers daily and takes occasion to point out that the "deadly third rail" did not kill or hurt a single passenger. Attention is also directed to the large order from the New York Central system for apparatus to operate as far out as Croton, 34 miles from New York City. It is shown that the percentage of operation has thus been cut down by the adoption of electricity: South Side Elevated, Chicago, 1895 steam, 69.1 per cent. of operating expenses to gross receipts; 1899, electricity, 44.1 per cent. Lake Street Elevated, 1895 steam, 56.1 per cent.; 1899 electricity, 47.5 per cent. Manhattan Elevated, 1901 steam, 55.8; 1903 electricity, 44.7. The detailed figures of the Manhattan, already familiar, are recited. General Griffin also calls attention to the great success of the Sprague-General Electric multiple-unit control now in use on 53 roads and 2,595 cars and adopted for London and Paris. The striking statement is made that since 1892 the company has sold 92,557 railway motors of a total capacity of 3,420,537 hp. As to power transmission, including steam and water plants, the company has installed or under contract 1,230,270 hp in polyphase generators, of which 514,910 hp is driven hydraulically. The number of orders received during the year was 176,834, or about 570 per cent. It appears elsewhere in the report that there were 15,500 regular customers on the books—more than 1,000 increase over 1902-3. General Griffin does not give the output of incandescent lamps.

Vice-President Rice presents an interesting report from the production end. The floor space has increased 700,000 ft. in 1903 and is now 3,700,000 ft., as compared with 1,800,000 ft. in 1899. The employees are 17,000, as compared with 8,000 in 1899; but are 1,000 fewer than in 1902-3, a fact that may quite largely be attributed to increased use of automatic machinery. To the incandescent lamp factory at Harrison, N. J., 4,200,089 ft., were added. The new turbine shop at Schenectady is 237,000 sq. ft., and one for the same work at Lynn has 137,000 sq. ft.

Mr. Rice notes the average increase of transformers in transmission plants from 100 kw to 1,000 kw, and the maximum size from 300 kw to 2,500 kw. The company had five large plants under construction with line pressures of 60,000 volts. One interesting item is the order from the government of Mysore, India, for 5,000 hp of generators, thus nearly doubling the original Cauvery-Kolar plant. At Niagara power plant the General Electric Company now has eleven generators of a total of 55,000-hp capacity; it has shipped the first 10,000-hp machine for the Canadian side of Niagara and has two more coming along for delivery.

Attention is called by Mr. Rice to the increase in the Baltimore & Ohio plant of two large multiple-unit locomotives; the order for 30 locomotives, each of 2,500 hp, for the New York Central, "the forerunner of many others to be placed by steam railroads," the introduction of single-phase railway motors, and the large exploitation of the Curtis turbine. "We made an arrangement with the inventor (Mr. C. G. Curtis) of this turbine a number of years ago, and as a result of his work and of that of our engineers, a type of prime-mover has been developed especially adapted for driving electrical generators. A large line of turbo-generators varying in size from 1½ hp to 7,500 hp has been developed. We have sold about 350,000 hp, of which 35,000 hp have been installed and are in successful operation. It is believed that the low cost, simplicity, small space and many other advantages of the Curtis turbine will result in a greatly increased sale of electrical apparatus." Mr. Rice mentions the fact that $2,500,000, exclusive of tools and patterns, was spent on the new shops in the year.

The financial report of the company states that outside of the Stanley "deal" the sum of $553,733 was spent on patents and patent litigation. It appears that the factory plants are carried on the books at $6,500,000. The total book value is $18,254,046, but in 11 years not less than $11,754,046 has been written off against them. Stocks and bonds of the company of a value of $24,340,000 are carried at a book value of $14,665,346, including 104 lots carried at $1 each. During the year securities carried at $1,156,812 were sold at a profit of $138,644. Collections during the year in cash exceeded $39,000,000. The unmatured and unsettled balances for the year are $14,548,450 and the total book value of all notes and accounts receivable was $15,207,480. The company had a balance of $2,046,488 engaged in work in progress on 816 incomplete installations. The office furniture, etc., of an appraised value of $166,059 is carried at $1. Finished apparatus worth $139,798 for novel uses had been delivered to various concerns subject to purchase if its operation is successful, such apparatus consigned and loaned being carried at $69,899. The company has no notes out and has virtually had no such obligations since 1895. Practically all purchases have been paid for in cash, although the company would appear to allow on an average slightly better than three months' credit to its customers, gauged by the accounts receivable. The total stock outstanding is $43,866,700, including $1,972,100 for the Stanley purchase. The total debentures is $2,131,400, including $2,049,400 for the Sprague purchase. A foot note to the financial statement by Messrs. H. W. Darling, treasurer, and E. Clark, general auditor, says: "The Stanley Electric Manufacturing Company, the stock of which was acquired by the General Electric Company early in 1903, carries a floating indebtedness of about $2,500,000, which it is proposed to liquidate in the near future." The balance sheet gives the cash on hand as $3,298,445 and the stocks and bonds owned as $14,665,346.

Chicago Meeting of the A. I. E. E.—Transmission Lines.

The Chicago branch of the American Institute of Electrical Engineers met April 26 to discuss the general subject of "High-Tension Transmission Circuits." At this meeting it was announced that the regular June meeting of the Institute will be held in Chicago on or about June 21, the programme to be confined to the transmission subjects. The date given was selected so that members could take advantage of the railroad rates to the Republican National Convention, as the meeting is expected to bring together transmission men from both East and West. Mr. James Lyman, chief engineer of the Chicago office of the General Electric Company, is chairman of the local committee on arrangements.

Mr. G. H. Lukes, general superintendent of the North Shore Electric Company, abstracted his paper on "Overhead High-Tension Distributing Systems in Suburban Districts," which was read at the New York meeting December 18 last. He also abstracted the paper of W. C. L. Eglin on "Automatic Apparatus for Regulating Generator and Feeder Potentials," which was read at the same New York meeting.

In discussing these papers, Mr. Lukes mentioned trees as an uncompromising source of trouble on overhead lines, and said that there was no tree insulator which was worth anything on high-tension circuits. The only way out of the difficulty was to keep the lines entirely away from the trees. As to the recent suggestion of the fire underwriters that crossing of overhead lines be made with poles so high and of such a short span that a wire breaking at one pole should not hang down far enough to reach the line crossing below, he did not think this advisable, because poles high enough to accomplish this would make the weakest point in the line. He thought it better to take some other risk than to introduce such weak points in the line. The grounded network of guard wires under the high-tension wires, if made sufficiently strong, would cause a serious additional strain on the pole supporting it, which he considered an element of danger.

Mr. H. B. Gear gave some of the practice of the Commonwealth Electric Company as regards constant-potential, alternating-current distribution lines. He said that in former days when circuits were operated at 1,000 volts and when there would be not over 20 or 25 kw load on a branch circuit, link fuses on a porcelain base for branch circuits were tolerably satisfactory; and when these fuses blew they caused no more inconvenience than the cutting off of service on that branch until a lineman could replace the fuses. On the present 2,000-volt circuits, however, the load on a branch was likely to be from 50 to 70 kw. The blowing of fuses on a 2,000-volt circuit of this capacity nearly always resulted in the destruction of the fuse box. Enclosed fuses were good, but when exposed on a pole line for some months the filling of the cartridge would become packed and the results when the fuse blew were nearly as bad as with an open fuse. The question, therefore, resolved itself into using as few fuses as possible. This company had adopted the practice of connecting various circuits solidly into junction box distributing centers without fuses. Small branch circuits were sometimes fused, the first pole away from the junction box, but the station fuses on a feeder were mainly depended upon to open short-circuits, and in case of a short-circuit on the lines, all of the customers on a feeder would be cut off for two or three minutes, while a fuse was being replaced at the station, as against the old arrangement of cutting off possibly one-third of the consumers on a feeder for two or three hours, while the lineman could reach the fuse box and repair the damage, perhaps being obliged to put a jumper around the destroyed fuse box.

Lightning arresters give satisfaction, but must be cleaned and repainted often. When old the collection of rust and dust is likely to cause trouble. They must be cleaned and painted at regular intervals. It is the custom of some companies to disconnect lightning arresters in the fall, connecting them up again before the spring thunderstorms. In a large system regular inspection of arresters by inspectors is absolutely necessary to good service. The greatest trouble which is found with wires is caused by boys, as they threw light wire across the lines with highly fascinating results. With the use of a suitable hook, an inspector could remove strings thrown across the line which were likely to cause trouble. He criticised the location of the various circuits on a pole which was suggested by Mr. Eglin. That arrangement was to place the alternating-current distributing circuit on the top cross arm, leaving arc circuits on the lower and outside arm, with the idea that these circuits would be dead during the day and that the lineman could work upon them. Mr. Gear said his company found it more satisfactory to place the alternating-current distributing circuit on the lower cross arm, where taps to transformers could be easily taken off and brought direct to the transformer. If the distributing circuit was placed on the top cross arm it was very difficult to make transformer connections to it. Furthermore, this distributing circuit was the one upon which most of the work had to be done, so that it was desirable to have it in the handiest place.

This company made an inspection of the oil in transformers about a year ago, and found that a large per cent. of them needed filling, the oil being from three to ten inches low. Many cases of transformer burn-outs were due to the absence of oil in transformers.

As regards the use of head guys from one pole to another, he considered them worthless as protection against wind storms, and cited examples of pole lines in Chicago protected by head guys, which had entirely gone down where pole lines alongside protected by side guys had remained intact.

Mr. E. P. Warner, chief engineer of the Western Electric Company, in discussing question of guys and their insulation, thought that no strain insulator was made which would protect a guy wire from circuits of 1,000 volts and over. Guy wires should all be grounded. He also thought that confidence should not be placed on an absolute cut-out on a series arc lamp, but that the lamp should be treated as if it were connected to the line.

Mr. Lukes agreed with Mr. Warren that guys should be grounded and that no dependence should be placed on absolute cut-outs in a large circuit. His instructions to men were to use an insulating stool whenever handling arc lamps on a live circuit. If it was a rainy night it was best to leave the lamp out all night than to risk handling it even then. For a strain insulator in a guy wire he thought a long stick of wood soaked in some water-proofing compound the best thing yet proposed.

Mr. J. D. Nies, instructor in Lewis Institute, gave an abstract of a paper by Harris J. Ryan, on "The Conductivity of the Atmosphere at High Voltages," read at New York, February 26, 1904. This paper was discussed by Prof. C. E. Freeman, of Armour Institute.

The paper on "European Practice in the Construction and Operation of High-Pressure Transmission Lines and Insulators," by Guido Semenza, read in New York, February 26, was given in abstract by W. A. Blanck.

Mr. Blanck said that the designing engineer in this country has been brought to seriously consider a more substantial pole line construction, which consideration culminates in the question of wooden versus iron poles. Most of the troubles on the present high-tension lines in this country with wooden poles and cross arms can be traced to the following causes: 1. Breaking of insulators. 2. Burning of pins and cross arms. 3. Damage to wooden poles by lightning, prairie or incendiary fires, and also loss by theft where fuel and building materials are scarce. A transmission line with iron poles set about 600 ft. apart reduces the number of line supports to about 20 per cent., as compared with that of wooden poles. It is, therefore, obvious that the points where break-downs may occur are reduced at the same rate, and considerably less maintenance is required. Difficulties as noted under two and three are avoided with iron poles and cross arms. The insulating capacity of a wood cross arm, in case of a broken glass insulator, for line potentials from 40,000 to 60,000 volts seems often to be overestimated. A proper form of porcelain insulator, made up of very tough material, firmly cemented to an iron pin, which, in case of a shot or blow, is not completely shattered but only chipped, will surely prove just as satisfactory as the above-mentioned insulating properties of the wooden cross arm. If the iron poles are set 600 ft. apart, the sag for the hard-drawn copper wire or cable should not be less than 2 per cent. of the span, or 12 ft. at 10° F., allowing the factor of safety to be about four. At 100° F. the deflection of the wires will be 20 ft., thus requiring 45-ft. towers. Assuming that the strongest wind sway takes place at the highest temperature just before a thunder storm and spacing the wires in an equilateral triangle with 7-ft. base, a contact of the two lower wires swinging in opposite directions could occur with only 10° deflection over the vertical plane. This deflection is very small and involves a great risk, and a considerably larger spacing would require very heavy cross arms. A suitable staggered position of the wires determined by the striking distance of the line pressure appears more advantageous for spans of 600 ft.

The tendency in this country is to build steel poles for power transmission lines, with a much larger base than the cuts indicate in Mr. Semenza's paper, thus doing away with the extra concrete foundations and considerable labor in erection of the poles. In order to keep the poles free from rust, all steel parts should be heavily galvanized after all punching, shearing or other machine work is done. Such a manipulation involves a higher first cost, but reduces immensely the maintenance or renewing of preserving paint.

Looking over Mr. Semenza's comparative figures for wooden vs. iron poles, the peculiar item for right of land occupation is to be noted. This differs materially from conditions in the United States. It is not considered good practice here to secure less than a full right-of-way for the complete transmission line, because nothing short of this enables the patrol gang an easy access to all parts of the line. In general, the territory for power transmission lines in the United States is more scantily settled and heavily wooded than abroad, so that highways are the most favored routes, allowing the best access to all parts of the line with the least expenditure for the right of way. These conditions for full private right of way require, therefore, the same investment for wooden and iron poles, and the table corrected for American prices and iron poles as specified would be as follows:

53 wooden poles, 35 ft. with cross arms and pins	$6.00	$318.00	9 steel towers with cross arms and pins 45 ft.	$60.00	$540.00
Erection	1.20	63.60	Assembling & erection	7.00	63.00
3x53 insulators	1.50	238.50	3x9 insulators	1.50	40.50
		$620.10			$643.50

"These figures certainly bespeak for the iron poles most careful consideration in long-distance transmission work. Through the courtesy of Mr. Dyer, of the Aermotor Company, Chicago, I am pleased to be able to show you this evening some lantern slides of steel towers built by this company for the Guanajuato Power & Electric Company, Mexico." (See Figs. 1 and 2.)

Mr. L. A. Sanford, who was connected with the construction of the Guanajuato 100-mile steel tower transmission line, then gave a very interesting description of this new departure in transmission line construction. From the power house at Zamora the line passes through thirty miles of rough mountainous country covered with lava rock and cut by deep ravines. The remaining seventy miles lie in a clear rolling country mostly under cultivation. With the exception of a few angles near Guanajuato, the line is almost straight. Three methods of construction were available: wood poles, iron poles and towers. Since native timber is not durable enough for pole line purposes, and Texas timber is expensive to import, many high-tension lines in Mexico are built of tubular steel poles.

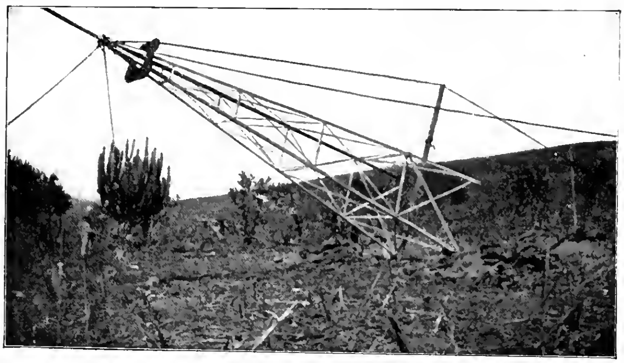

FIG. 1.—RAISING A TRANSMISSION LINE TOWER TO POSITION.

FIG. 2.—ONE OF THE TRANSMISSION LINE TOWERS.

As the line was one of the vital points of this installation, it was desirable to make it both electrically and mechanically as strong and durable as possible. Each insulator of a high-tension line is liable to puncture and breakage, and is, therefore, a point of weakness. By long spans the number of insulators and consequent weak points may be decreased, but it is necessary at the same time to increase the strength of supports and cables.

The Locke insulator used (see ELECTRICAL WORLD AND ENGINEER, January 24, 1903), consisted of three pieces. The pin sleeves and petticoats already cemented together were shipped in barrels separate from the tops. After arrival on the line, the two parts of each insulator and the pin had to be cemented and allowed to stand for forty-eight hours before they could be distributed to the respective towers. The tower construction requires 108 insulators less than a wood pole construction with forty-eight poles to the mile. Here is a large saving in cementing the insulators and in breakage, as it is almost impossible to pack large insulators in baskets on mules and burros for two or three miles without some damage.

Transportation was a big item, both from the States and after the material was unloaded from the cars. On the rough section of the line wagon roads were very scarce, and it was often necessary to pack construction materials for four or five miles over rough trails. The Guanajuato towers (Figs. 1 and 2) weigh 1,500 pounds apiece, and are of the four-post wind mill type, standing 40 ft. above the ground, on a base 8 ft. square. As in wind mill towers, about the top is a square wooden platform extremely convenient to work on. The top insulator pin screws on the end of a 3-in. iron pipe extending 6 ft. above the top of the tower. The two 4-in. channels forming the cross arm clamp about the base of this pipe, and the square bases of the cross arm pins fit between these channels. The towers are not set in concrete, as is sometimes the custom with iron poles, but the four legs each carry a 3-in. piece of angle iron, which rests on the bottom of the post holes. These cross pieces answer the purpose of both supports and anchors. The four post holes are filled and tamped in the ordinary manner.

At the present price of steel, the tower weighing 1,500 pounds complete with cross arms and pins, in lots of 500, cost $53 apiece. They are claimed to withstand safely a transverse strain of 3,500 pounds applied at the apex. Locke insulators No. 329, as used, cost approximately $1.50 each; thirty-six insulators at $1.50 and twelve towers at $53 bring the cost of insulators and towers to $690 per mile. The cost of excavating for these towers consists of the following items: First, excavation of four holes 1½ ft. x 3 ft. x 4 ft. deep, the cost of which will vary with the nature of the ground. Second, bolting the towers together. Third, erection of the towers.

"We found that a gang of six Mexicans could assemble three towers in a day. I do not doubt but that one man and three laborers here in the States could assemble four in the same time. In raising the towers one gang of twelve Mexicans with an American foreman frequently put up twelve towers a day. Cables of 19-strand hard-drawn copper about equal to No. 1 B. & S. came from the States on reels, each reel containing about two miles. Every four miles along the line six of these reels were unloaded from the wagon, and the cables strung each way over rollers placed on the cross arms of the towers. Our chief trouble lay with loose strands, due to injury in shipment and improper soldering of the loose ends at the factory. When a loose strand would catch in a roller it would strip from the cable, tangle and soon wedge tight.

"Two to five miles were used to pull each cable. Seven and one-half feet of sag was allowed between towers. In the rough country the slack was pulled up every mile and held with steel guy wires until the next pull could be made. In the level country a two-mile pull gave very good results. On an average, a camp could make four miles a day stringing, pulling up slack and tying in at insulators. Some difficulty was experienced in lifting the middle cable from the cross arm to the top insulator pins on towers situated on the summits of hills. In this case the weight of the cable is considerably greater than one-half the span at each side. All insulator tie wires were of No. 14 B. & S. soft copper, the idea being that the danger of nicking the cables was less with small tie wires, and in case of the cable parting it was better to break four or five tie wires than to loosen the tower. The cables were not transposed the total length of the line, but the telephone wires situated about seven feet below the cross arm were transposed every two towers."

When the voltage was first thrown on the line five or six cracked insulators were located and replaced. These insulator faults were probably due to injury in putting up, or after the line was completed. This would certainly seem a remarkable result considering the length of the line. On one occasion the strain of two cables under line tension was thrown at almost the same instant on the cross arms of a tower, by the breaking of two steel guy wires. The only effect was to twist the cross arm slightly and raise the tower out of the ground about six inches.

Mr. H. H. Wait was chairman of the meeting and many favorable comments were made on the excellence of the discussion for which he had arranged and the way the meeting was conducted, all of the discussions being full of meat and to the point.

New Telephone Patents.

SEMI-AUTOMATIC TELEPHONE SYSTEM.

Now that the telephone density, if it may be so called, is becoming so great that even with the multiple switchboard increased to a capacity far beyond the contemplation of its originators, the number of central offices required is ominously large, many inventors are turning their attention to the problem of attaining a satisfactory telephone switchboard of an ultimate capacity commensurate with the present demands. Divided multiples have been tried and recently there have been developed purely automatic systems arranged for numbers of subscribers approaching ten thousand. Another system has now been brought forward under the name "semi-automatic," this the invention of E. A. Fuller, of New York City. In this system the subscriber's line terminates in answering jack and line lamp at the central office, and is provided with an automatic sender at the outside end. When it is desired to send a call, the subscriber sets his sender to the desired number and starts the call, this being indicated to his operator by the lighting of his line lamp. The operator responds by cord and plug, as is usual with manual boards. She has no listening key, however, but instead a key which when thrown connects a number receiving device to the line and also automatically starts the subscriber's sender. The sender does not complete its signal, but merely records the thousands and hundreds numbers of the desired line upon the receiving device of the answering operator. She, noticing these, selects a trunk to the operator having the desired line, and completes the connection thereto, causing a calling-in lamp to light. This operator responds in a manner similar to the first, except that she receives on her recorder the tens and units digits and may, therefore, complete the desired connection and ring both subscribers. The taking down of a connection proceeds in the reverse direction, the placing of a receiver on the hook controlling lamps at the position of the connection completing operator.

REPEATER.

Under the name "Megaplex Relay," R. A. Engler, of Dubuque, Iowa, has patented a repeating system. The repeater is a multiple affair, each element consisting of an open magnetic circuit induction coil, opposed to one pole of which is an armature. This armature is supported from the diaphragm of a transmitter, which, therefore, is subjected to a vibration corresponding to the currents passing in the induction coil. A series of these units are interconnected, the primary of the first coil being connected to the incoming line, while the primary of the coil of the second unit is in circuit with a battery and the transmitter of the first unit, and so on until the last unit, the transmitter part of which is omitted. The induction coil secondaries are all wired in series and then connected to the outgoing line.

AN ODD TELEPHONE APPARATUS.

An odd telephone apparatus has been patented by M. Beck, of Minneapolis. There are three parts concerned in its working, two substation sets and an intermediate contact-maker and battery. The combined receiver and transmitter is peculiar, as the mouthpiece is of sheet iron so flanged that a recess is provided for an annular coil. The diaphragm is immediately behind the coil, the rearward surface of the flange of the mouthpiece serving as a support for it, while the inner edge of the orifice serves as the receiver pole. Contacting with the diaphragm is an insulating ring wound with bare wire. The contact of the diaphragm with this bare wire coil of high resistance depends upon the convexity of the former. The primary current is carried through this coil of wire, the shunting of its turns by the diaphragm serving to set up the undulating voice currents. The receiver coil and this transmitting contact are in series. An ear tube extends from the rear of the diaphragm for conveying the received sounds to the user. The talking currents are furnished primarily from the intermediate battery, the efficiency of transmission being controlled, it is stated, by the aid of rheostats at the end stations.

A step-by-step selective device and a receiver support are the subjects of the two remaining patents. Of these the former was invented by L. E. Brock, of Celina, Ohio, and the latter by J. A. Brown, of Warren, Ohio. Each includes the features usual with apparatus of their respective kinds.

A NEW SYSTEM OF SUPERVISING SIGNALS.

While in most cases the present standard two-lamp supervisory signal system is amply sufficient, its indications sufficiently informing the operator of the progress of a connection, there is one condition of indefiniteness included in it. The appearance of the signals is exactly the same before the called subscriber answers as it is after either one of the subscribers has, without the other, hung up his receiver; and further, while the first of these demands additional ringing on the part of the operator, the second signifies probably just the opposite, namely, that the subscriber remaining on the lines desires the operator to get him a second subscriber. It may be argued that there is little likelihood of confusion occurring in practice, because the interval of time which would usually occur between this condition of signals. However, that such confusion undoubtedly does arise is best testified to by the fact that a system of signals has been invented to overcome the difficulty. The inventor of this system is E. H. Smythe, of Freeport, Ill., the patent being assigned to the Western Electric Company. The invention lies in providing means for automatically controlling the current supply to the supervisory circuits, so that the lamp glows steadily, or gives flashes at different rates, to signify more positively the exact condition of the connections. The ringing signal is steady; a fast flash is used to indicate "disconnect," being introduced by the simple replacement of the receiver on the hook, while a slow flash is used for a "recalling signal," being introduced by the mere removal of the receiver after once depressing it. The removal of the operator's plug or her "listening-in," restores the circuits to the proper condition for subsequent use.

OFFICE DESK TELEPHONE SET.

Mr. A. R. Ferguson, of New York City, has patented a swinging arm telephone set of rather novel design, in that the plane of swing is vertical. The base is adapted to clamp upon the top of a desk, and it carries on a hinge a straight telescoping tube, upon the end of which is carried the hook switch and transmitter. A perforated ear on the receiver engages a button on the hook switch lever, and thus it hangs in a vertical position irrespective of the angle of the arm with the horizontal. The weight of the receiver is, on the other hand, effective in depressing the hook switch only when the arm is vertical. Therefore, after using the set the arm must be pushed up out of the way. The patent for this arm has been assigned to the Electro-Mechanical Specialty Company, of New York City.

ADJUSTABLE RECEIVER.

In ordinary telephone practice it is not thought necessary to adjust the sensitiveness of the receiver for different users; in fact, the present tendency seems to be toward having no adjustment at all. However, when used to assist the deaf to hear, the sensitiveness of various ears or the different degrees of deafness, render an adjustment at times advisable if not necessary. M. R. Hutchison, of Norwood, N. J., has patented an adjustable receiver for this work, adjustment of the air-gap between diaphragm and pole faces being effected by screwing the cap piece farther or less upon the body. An arbitrary scale of adjustment enables one to reset to the same position at different times, while a friction pin lock prevents any accidental change of adjustment.

HOOK SWITCH ESCUTCHEON PLATE.

The peculiar shape of a hook switch has always rendered it difficult to use other than a two-piece escutcheon plate where it passes through the side of telephone box. This of course renders it necessary to use four screws to secure the plate. A one-piece plate has now been invented and patented by A. C. Christopher, of Chicago. In this plate a slit is cut from the slot to the edge of the escutcheon in a line at right angles to the slot for the lever. By suitably turning and twisting the plate, the lever may be threaded through the slit into the slot, the plate being temporarily distorted to permit of this. The Kellogg Switchboard & Supply Company has obtained the patent for this device, by assignment.

Some New Data on the Edison Storage Battery.

In a very interesting lecture delivered before the New York Electrical Society at the rooms of the American Institute, New York City, on April 27th, on the occasion of the Society's two hundred and forty-second meeting, Mr. R. A. Fliess, who for some years past has been associated with Mr. Edison in the development of the nickel-iron cell, outlined the steps that led up to the discovery of the Edison cell, and then described its gradual development to its present state of perfection.

The various steps that have marked progress in the development of the cell were illustrated by means of lantern slides. Several curves were shown in which are recorded the progress made in the development of the active materials at different periods in the development of the cell; also a number of photographs taken at different times during the past few years by Mr. Fliess, in which vital moments during the period of development are preserved.

Mr. Fliess began by pointing out the great amount of preliminary work that had to be gone through before Mr. Edison had reached the point in his search after a secondary cell such as he desired where he felt justified in beginning operations on a large scale. Mr. Edison set himself the task at the outset of his search after a commercial solution of the light-weight secondary cell that should possess as many as possible of the following desirable features: 1. Absence of deterioration by work. 2. Large storage capacity per unit of mass. 3. Capability of being rapidly charged or discharged. 4. Capability of withstanding careless treatment.

Mr. Fliess pointed out that among his early attempts Mr. Edison made an attempt to develop his well-known Edison-Leclanche primary cell into a commercial secondary cell, and that consequently at an early date Mr. Edison already had under close observation two of the three elements that composed his first solution of the light-weight secondary cell problem, i. e., the copper pole and the alkaline electrolyte. They, in connection with cadmium, comprised his cadmium copper cell—the first of several solutions of the light-weight secondary cell problem reached by Mr. Edison before he hit upon his nickel-iron combination.

The general method of investigation adhered to by Mr. Edison throughout his search for a solution of his problem was described and photographs of the apparatus used were shown. Mr. Edison used little pockets stuffed with the active material he wished to investigate during his early experiments. These were subjected to the oxidizing or reducing action of the electric current and were then discharged against an excess of active material of the opposite kind. By means of an elaborate system of testing Mr. Edison followed very accurately and quickly all improvements made in the ampere-hour and watt-hour capacities of the active materials, and curves were presented that showed at a glance the improvements that were made during the period in which Mr. Edison was attempting to develop the ampere-hour and watt-hour capacities of his nickel and iron elements.

In six months an increase of over 72 per cent. was recorded in the ampere-hour capacity of the nickel and over 83 per cent. in its watt-hour capacity. In another six months a 33 per cent. advance was made in its ampere-hour and a 35 per cent. advance in its watt-hour capacity; or, in other words, in the short space of one year an increase in the ampere-hour capacity of the nickel per gram was made of over 128 per cent., and an increase in its watt-hour capacity of over 148 per cent.

The improvement recorded in the ampere-hour and watt-hour capacities of the iron was equally remarkable. In six months an increase in its ampere-hour capacity of over 40 per cent. was recorded and in its watt-hour capacity of over 48 per cent.; while in another six months an increase of over 70 per cent. in ampere-hour and of over 75 per cent. in watt-hour capacity was made; or, in other words, in the short space of one year an increase of over 139 per cent. was made in its ampere-hour capacity and of over 159 per cent. in its watt-hour capacity.

During the course of this development over 10,000 separate tests were made on little test grids containing samples of iron and nickel and as between 80 and 100 observations had to be made during a single test more than 100,000 observations were made and recorded while the improvements mentioned above were being made. Mr. Fliess mentioned this to give an idea of the enormous amount of detailed work that the development of an invention of any pretentions involves.

It was not until about the first of February, 1902, that Mr. Edison had advanced far enough to make up a large-sized cell with automatic tools. About this time, however, he received at his laboratory in West Orange the first large-sized cell ever made completely with automatic tools. The mechanical parts of this cell had been made at the mechanical works at Glen Ridge, N. J., and the active materials at the chemical plant at Silver Lake, N. J.

This cell was composed of nine nickel and nine iron plates, contained in a steel jar, and covered by a steel cover through which the binding posts protruded. A number of cells soon followed and on the 3d of April, 1902, a little Baker electric vehicle equipped with twenty-one cells started out for a first spin in which an automobile had ever been propelled by power obtained from Edison cells. A picture of the vehicle at the moment of starting was shown.

TABLE I.

Type.	Discharge rate.	Output.
C	30 amperes	229.6 watt hours
C	120 amperes	175.25 watt hours
D	30 amperes	212.2 watt hours
D	120 amperes	191.5 watt hours
E	30 amperes	272.5 watt hours
E	120 amperes	240.6 watt hours

This first type of cell was called the "C" type. It had one or two characteristics that Mr. Edison did not consider desirable, so he soon set out to produce a cell that should not possess the features of the "C" type he wished eliminated. The result was the "D" type cell. The "C" type cell, however, even though Mr. Edison did not approve of it entirely, still showed marked improvement over the light-weight automobile type of lead cell to-day. Mr. Fliess supported his statements by means of curves. The objection Mr. Edison had to his "C" type of cell was that it did not stand up well under high rates of discharge. That is to say, it lost something over 37 per cent. of its normal capacity when discharged at five times its normal rate. A lead cell under similar conditions, however, Mr. Fliess pointed out, loses over 50 per cent. of the capacity it has at its normal rate.

Some "D" type cells were ready about May, 1903, and were at once subjected to a very severe test in automobiles. This cell was composed of fourteen nickel and fourteen iron plates. It occupied the same space as did the "C" cell, but the active plate surface was over 35 per cent. greater, consequently the discharge rate should be much greater. That this was so, the curves that were shown by Mr. Fliess demonstrated very clearly. Instead of the 37 per cent. loss in capacity suffered by the "C" cell at a five times normal discharge rate, it showed but a 10 per cent. loss under similar conditions. This high discharge rate feature had been obtained, tests showed, at the sacrifice of ampere-hour capacity. Consequently, the weight per hp-hour had gone up as compared to that shown by the "C" type cell. Also, Mr. Edison found by experience that the very high discharge capacity of the "D" type cell was seldom called upon in practice. He therefore decided to build a third type of cell in which the great ampere-hour capacity of the "C" type and the high discharge rate capacity of the "D" type should be preserved in just the right proportions. The result was the "E" type cell. This cell is made up with two nickel plates for every iron plate. In external appearance, however, it looks just like the two types it has superseded.

Its electrical properties, however, are a great improvement over the two earlier types, as the preceding table will show.

As the weights of the "C", "D" and "E" types, data from which are recorded in the table are exactly the same, a direct comparison may be made. It will be noticed that the "E" type cell is capable of giving out a greater amount of energy per unit of weight and volume at a 120-amp. rate of discharge than either the "C" or "D" types were able to give out at their normal rates of discharge.

An analysis of the figures just given in the table show the following results in pounds per hp-hour:

TABLE II.

Type.	Discharge rate.	Lbs. per H.P.H.
C	30 amperes	56.87
C	120 amperes	74.48
D	30 amperes	61.6
D	120 amperes	68.25
E	30 amperes	47.75
E	120 amperes	54.25

From the figures in Table II it will be seen that the "E" type cell is very much superior to the two types that preceded it, and would seem amply to justify Mr. Edison in his determination to delay the commercial production of his cell on a large scale until he could complete tools and factory facilities for turning out his "E" type cell in large numbers. These preparations were finally completed some little time ago.

Mr. Fliess then showed curves that illustrated very clearly the remarkable life and endurance that the Edison cell seems to possess. Curves were shown taken from a cell at different periods during the past three years and after three years of knocking about the laboratory, during which time the cell received absolutely no attention or care. The curves showed the cell to be in absolutely the same condition that it was when first tested. Another slide was shown in which curves of the 1st, 350th, 804th and 970th discharges on a little endurance test, kept running night and day at Mr. Edison's laboratory for over a year, were recorded. These curves showed that in this time absolutely no change had taken place in the capacity of the unit or in the shape of its discharge curve. Curves were then shown that had been obtained from a standard "D" type Edison cell just before and just after a 4,000-mile test in an automobile under the most severe conditions that could be imposed upon both the vehicle and the cells. The curves showed that after this severe 4,000-mile test the cell ran, if anything, slightly better than it did when first placed in the automobile; certainly a very refreshing result as compared to those we have been familiar with in the past. Curves were then shown taken from a cell that had traveled over 5,000 miles in an automobile under most severe conditions. The first curve was obtained from the cell before it had ever been put in the vehicle. The second after it had completed its 5,000-mile test. The curves showed that at the end of the test the cell gave over 13 per cent. greater capacity than it had done before it went into the vehicle.

This cell was exhibited with its can removed and the plates appeared to be in identically the same condition as new ones exhibited beside it.

A bottle was shown in which the deposit found in a cell after a 4,000-mile test was preserved. It was so small in amount that no accurate weight could be obtained of it on a scale weighing in ounces. In fact, the deposit amounted to but a few grams in weight, and, as Mr. Fliess pointed out, had probably nearly all been in the bottom of the cell before it ever went into the vehicle.

An interesting discussion followed, in which some criticisms made on the cell were directed chiefly against its great bulk and its high price. Mr. Fliess replied briefly.

CURRENT NEWS AND NOTES.

WIRELESS IN THE WAR.—With regard to the brilliant work of the little steamer *Hai-Mun* off Port Arthur, a cable dispatch from London of April 26 says: "The steamship *Hai-Mun*, on which is the De Forest wireless telegraphy apparatus by means of which dispatches from the seat of war are sent to the London *Times* and the New York *Times*, has gone to Nagasaki to clean up and refit. The *Hai-Mun* had been in continuous service for six weeks."

THE STEAM TURBINE DEFINED.—A local newspaper describing the new Westinghouse turbine plant installed at the works of the Union Metallic Cartridge Company, Bridgeport, Conn., says: "An interesting feature of the equipment is a steel turbine equipment of 3,000 hp. The turbine is a reciprocating engine with a piston rod that extends back and forth instead of in a circle and is the most modern. It is compact and takes up less room than other styles, and is now in use in many of the first-class manufacturing establishments."

A STATE TROLLEY LINE has recently been put in operation at Bismarck, N. D. The State Capitol is a little over a mile from the hotels and depots and it did not pay to operate a trolley line out to it, so that hack charges have been heavy, while on account of limited accommodation in the building many committee rooms have had to be rented in the city. Under these circumstances, which reflect no credit on the locaters and designers of the Capitol, the building is being enlarged and the State itself has equipped and is operating a trolley line with one car, while the exhaust steam from the power plant is to be used in winter for the new wing of the capitol.

AUTOMOBILE PARADE.—A parade of automobiles was given last week in New York City under the auspices of the Automobile Club of America. Over 225 vehicles were in line and double that number were ready, but a heavy rain storm spoiled things considerably, while the slow speed maintained caused many of the big gasoline touring machines to drop out on account of heating up. The line through the parks and drives included 39 foreign vehicles, and there were 8 American electrics. The commercial division traveling outside the Park made a remarkable appearance. There were nearly 80 such vehicles in line, of which no fewer than 59 were electric and 2 were combination electric-gasoline. It was a fine demonstration of electric capabilities in this direction. Mr. J. D. Rainier was marshal of this division, which included several of the service vehicles employed by the New York Edison Company.

IOWA TROLLEY ASSOCIATION.—The Iowa Street & Interurban Railway Association was formed at Des Moines April 21, at a meeting of the representatives of seventeen such companies operating in Iowa, held at the Kirkwood Hotel. The creation of this association is due to the efforts of George B. Hippee, general manager of the Des Moines City Railway. It was at first thought, as already noted in these columns, that the street railway men might join in with the Iowa Electrical Association, which held its regular annual convention in Des Moines at the same time. After a conference between representatives of both, however, it was decided that it would be better to keep the two organizations separate, with the understanding that for the present the conventions of the Iowa Street and Interurban Railway Association and the Iowa Electrical Association shall be held at the same place the same week; and made to overlap one day so that topics of interest to both lighting and railway men can be taken up that day. The officers elected were: George B. Hippee, of Des Moines, president; J. F. Lardner, of Davenport, vice-president, and L. D. Mathes, of Dubuque, secretary and treasurer. The constitution provides that the membership shall consist of companies or individuals operating street or interurban railways in the State of Iowa. The admission fee is $10 and the annual dues are $10.

LETTERS TO THE EDITORS.

Patent Law Reform.

To the Editors of Electrical World and Engineer:

SIRS:—I was much interested in your editorial on "Patent Law Reform" and would suggest an extension to its recommendations, namely, that where a patent is found inoperative, as fully one-half of the patents now in force are, the said patent shall, by the government, be declared invalid; and if a subsequent inventor should embody some of its features in an operative device, he shall be allowed a patent thereon as though the invention were new in all of its details. Many of the inoperative patents now in force are a bar to useful invention. It is true that even now, if one can prove a patent inoperative, it may be annulled, but this is an expense that the majority of inventors cannot afford.

In conclusion, I may call attention to the fact that the State will now pursue a horse thief and try him in court and imprison him at the expense of the State; but if a party pirates an invention, for the patenting of which the inventor has paid all that the government demands, he must, at his own expense, bring suit to secure the right which he is told in his letters patent the government has granted for his money. This seems to me wrong in justice and equity.

Bellefontaine, Ohio. D. F. Tanger.

Our Patent System.

To the Editors of Electrical World and Engineer:

Sirs:—Your impressive editorial on April 16 on "Weak Spots in the Patent System" deplores the absence of any provision of law compelling patents to be worked as a condition of their continuing in force. With your general contention that patents might contribute even more powerfully than at present to the advancement of science and the useful arts, I cordially agree, but nevertheless I am constrained to think that you have mistaken the remedy.

That a patent has not been worked does not mean that the public gets no advantage from it. It enters into the art as really for the purposes of disclosure of the idea, of barring the way to a future patent, of limiting the claims of future patents, as though it were actually in practice in every workshop in the land. It is thus a stepping-stone to future advances. Again, a patent forfeited for non-user would just as effectually bar the way to another patent for the same invention as though it were in full force, and your suggestion that an unworked patent is sufficiently in the way to hinder material improvements or make it difficult to get proper claims or even claims sufficient actually to protect the new invention, ignores the principles that a prior publication as well as a patent is equally a bar to another patent upon the same subject matter, and so is an expired or invalid patent.

Returning to the remedy proposed, the compulsory working of patents within one, two or three years after they are granted, it must not be forgotten that the requirement cannot be applied to large classes of patents and those for the most important inventions.

A patent for a torpedo boat, a large gun or its projectile, an armor plate, a submarine cable, a railway construction or for the Parsons turbine could not be worked without an expenditure that would ruin most inventors. The Elmore process for recovering gold was worked on a commercial scale only by the expenditure of 50,000 pounds sterling. The Bessemer process was delayed for some time after the invention and could not have been worked for less than a ruinous sum to the inventor.

Only the trifles can be brought before the public by a compulsory requirement for working. Other inventions of importance at first are displaced and superseded by a later invention, as the making of aluminum by the aid of sodium was displaced by the introduction of the electrolytic process, yet to require the owners of the chemical patent to proceed with working on a commercial scale or forfeit their patent altogether would be a manifest injustice, for the patent was nevertheless valuable as a stepping-stone in the art to further inventions in the same direction.

This is not a new proposal, but has been repeatedly before Congresses and Parliaments with the result that the laws of England and the United States, the two greatest manufacturing countries in the world, contain no such provision.

At the Congress of the International Association for the Protection of Industrial Property, held in Vienna in 1897, it was unanimously resolved that it would in future be necessary to give up the principle of compulsory working; and where not altogether given up it has been unanimously agreed, for example, by the International Convention that the working of an invention in one State ought to be the equivalent of working in all; and in the countries of continental Europe adhering to this principle, there is a notable disposition to relax the requirement, and the whole trend of continental opinion is now adverse to compulsory working.

Germany, Switzerland and Italy have entered into an arrangement such that if an invention is worked in any one of these countries it is deemed to be worked in all.

But the fullest discussion arose in England two years ago, when the Manchester Chamber of Commerce, under the stimulus of the analine dye interests, pressed upon the Board of Trade the compulsory working feature as a provision to be inserted in the revised English patent law.

It is well known that England that year adopted the examination system for the grant of patents, and as the revision of her law was thoroughgoing this question of the compulsory working of patents was strongly urged and well considered.

The discussion eliminated many erroneous impressions and compulsory working was not only not adopted, but the body of opinion was strongly against it, and I believe unanimously against it, both in the Board of Trade and in the Parliamentary Committee.

One of the objections to a compulsory working clause in the patent laws is foreshadowed in your editorial—that it is difficult to determine to what extent and in what way a patent must be worked to satisfy the requirements of the law, and the owners of a patent can never know with certainty whether their patent is valid or not after the period for correcting their mistakes in this regard has passed. Men are thus dissuaded from risking capital in the invention on account of a new danger confronting them from this requirement.

Again, the inventor may not have the experience and practical capacity to work his patents even if he has the funds, for some of the most meritorious inventions have been made by people unfamiliar with the art.

The great advantage to a country of having as in America thousands of gifted men at work to improve the arts, machines, processes and compositions of matter which make up the world of the industrial arts is a resource and asset of the country that is too little prized.

Their reward is the exclusive use of their inventions and discoveries for the limited term of seventeen years upon the condition that they will fully disclose to the public all that appertains to them, and that the public may freely use them after the limited term has expired. The wisest policy is to give the patentee the best patent possible under the circumstances of his case divested of every embarrassment to enlisting capital in the undertaking and with every doubt upon his patent removed that the most competent administration of the patent system can remove.

Indeed, a serious complaint against any patent system is the fact that the seal of the government cannot be final as regards the question of novelty and patentability, because no country can tolerate the grant of a patent for what is already in the possession of the public. It must ever remain, therefore, a judicial question whether a patent once issued is in reality for that which is new and patentable or whether it was already within the knowledge of the public by former disclosures or by prior use, and to add this new danger to capital embarking on untried seas is to forbid and not to encourage the evolution and growth of the useful arts.

There are improvements in the issue of patents that are entirely within the scope of immediate useful reform. Both are in the process of development at the present time in our system. The collection and the classification of all material in print relative to the industrial arts is the requirement of the law as it stands, not only in this country, but in others. The practical realization is not yet fully reduced to fact in any country, not even in our own.

Yet great progress has been made and is now making and we may fairly anticipate that in reasonable further time every application for a new invention or discovery will be compared with everything that is in print upon the same subject matter—with the 2,000,000 patents in the aggregate granted in all civilized countries, with the scientific books, with the printed disclosures in the technical press and in other publications, and so grouped and classified that the examiner passing upon the new application as well as the applicant himself may expeditiously turn to that part of this matter which pertains to his invention and make the comparison himself.

It could, therefore, rarely happen that a patent would be wrongfully withheld, but in the absence of a direct interest opposing the patent some would issue that ought not. But with the record showing what was cited against it, the evils pertaining to the issue of invalid patents would be reduced to a minimum.

Second, the requirement of the Patent Office that inventions should be dismembered and split up into numerous applications and finally numerous patents upon related parts of the invention because they are capable of separate use, will ultimately pass away and should pass away.

The Supreme Court of the United States in the recent case of United States ex rel. Steinmetz against the Commissioner of Patents, decided February 23, 1904, cleared away a vast accumulation of error. It was there held that the statute gives the right to join inventions in one application in cases where the inventions are related, and that it cannot be denied by hard and fixed rule which prevents such joinder in all cases.

It may, therefore, be regarded as the settled policy of the law as interpreted by the highest court in the land that the applicant has rights in this matter of division and may come before the office with all that he has invented at one time concerning the same subject matter, and if the elements are related and co-operate, he may include them in one patent. What harm? None whatsoever. It is the desire of the applicant to have his subject matter in one patent. It is for the benefit of the public that it should be so, thus exhibiting to the world these various elements in their proper relation. The public are also freed from the embarrassment of having one element owned by one interest and another by another and perhaps conflicting interest.

Finally, there is a direct remedy for most of the evils which compulsory working is intended to eliminate, and that is a provision, not found in our law, for compulsory licenses. This has been a feature of the English law and in the revision two years ago simpler, quicker and cheaper procedure was provided to meet all cases where the inventor allowed his patent to slumber, either for justifiable reasons or because the patent had passed into hands that were interested in smothering it.

Any person interested may present a petition to the Board of Trade alleging that the reasonable requirements of the public with respect to a patented invention have not been satisfied and praying for the grant of a compulsory license or in the alternative for the revocation of the patent. If it is proved that the reasonable requirements of the public have not been satisfied, the patentee may be ordered to grant a license, or if the reasonable requirements of the public will not be satisfied by the grant of a license the patent may be revoked after three years from its date, unless the patentee gives satisfactory reasons for his default. And if it is proved that the patent is worked or the patented article is manufactured exclusively or mainly outside of the United Kingdom then also unless the patentee can show that the reasonable requirements of the public have been satisfied, an order will be entered for a compulsory license or for the revocation of the patent.

And the reasonable requirements of the public are defined to be that existing industries or new industries shall not be unfairly prejudiced and that the demand for the patented article is reasonably met.

These are the directions in which improvement may be found—perfect searches upon the question of novelty, a high degree of probability for the validity of the patent once issued, and second, the dangers of mutilation by the issue of several patents at successive times for the same invention, absolutely removed by abandoning the compulsory division of applications except where to grant one patent for the whole subject matter would be invalid by reason of the inclusion of distinct and unrelated subjects of invention.

New York. John S. Seymour.

Molecular Conductivities.

To the Editors of Electrical World and Engineer:

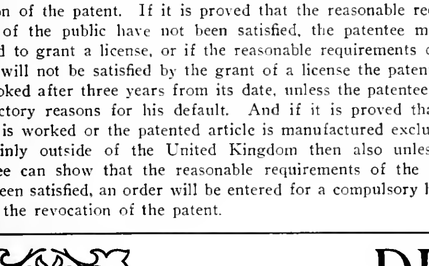
Sirs:—I would like to call your attention to the fact that in your editorial on page 719 of the issue of April 16 you have misquoted and misunderstood my paper on "Molecular Conductivity." If you had carefully read the paper and understood it, you would have found your criticism unnecessary. I was very particular to state exactly what I meant in the paper, which was "that all theoretical deductions based on investigations of molecular conductivities of different degrees of dilution have no physical significance." In your editorial you make me say "all theoretical deductions, based on investigations of molecular conductivities have no physical significance," omitting the very important words which distinguish my statement from yours. If you will take the trouble to examine my statement in connection with the facts, you will find it is absolutely correct.

Philadelphia, Pa. C. J. Reed.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Transformers.—Loewy.—In a continuation of his serial on recent progress in the design of electric machines he discusses advances made in transformer construction. Besides various new constructions of the General Electric Company and the Westinghouse Company, the following European designs are described: Fig. 1 shows



FIGS. 1 AND 2.—TRANSFORMER DIAGRAMS.

a three-phase transformer of the Schwarzkopff Company, in which the windings are so arranged that the magnetic circuits produced by the different phases do not influence each other so that an overload in one phase does not react upon the others. The transformer consists of a rectangular iron frame, *a*, with two iron cross-connections, *c*, parallel to the small sides, *b*. Each primary and secondary phase has two windings arranged opposite each other, as shown in the diagram. A similar transformer for two-phase currents, built by the Union Electric Company, is shown in Fig. 2. It has three iron cores, *a*, *b*, *c*. The winding of one phase is placed one-half on *a* and one-half on *c* in such a way that the current flowing through them has either the direction indicated by the arrows or the opposite direction. The winding of the second phase is placed on core *b*. It will be seen that those lines of force which are produced in *a* and *c* by the first phase and pass through the core, *b*, act against each other in *b* so that here only the flux produced by the second phase is effective. In the same way it may be seen that the second phase does not act upon the first phase. A single-phase transformer of the Thomson-Houston Company is shown in Fig. 3 for supplying two separate secondary networks or a secondary three-wire network in such a way that for any load in the secondary network the secondary voltages remain constant. The transformer consists of an iron frame, *C*, on the two long side arms of which the two parts, *Px* and *Py*, of the primary winding are placed. These two parts are in parallel with the circuit, 1, 2, and are so connected that the current flowing through them produces a magnetic flux closed in the iron frame as indicated by the arrows. The two secondary windings are arranged concentrically with the primary windings, *Px* and *Py*. If the load in one of the two secondary windings increases, then this winding will counteract its primary winding with greater force; that is, it will diminish the strength of the magnetic flux so that the counter e.m.f. of the primary windings decreases. For this reason the network will now send more current into this primary winding, so that the strength of the flux, common to the two secondary windings, is maintained. On account of this automatic regulation, the voltage in the secondary windings is maintained constant.—*Zeit. f. Elek.* (Vienna), April 17.

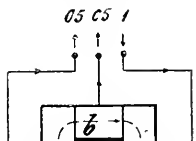


FIG. 3.—WINDING OF SINGLE-PHASE TRANSFORMER.

Electric Resistances of Bearings.—Dettmar.—A communication referring to the recent letter of Zorawski and the former tests of Kennelly (see page 231, Electrical World and Engineer, February 7.

1903). He has twice made a series of measurements of the resistance of bearings of electric machines and has always obtained results which did not agree at all with each other. While he tested the friction coefficient of various lubricating oils, he found that this coefficient decreases with increasing speed of the machines, and increases again afterwards. The minimum point of friction corresponds to the moment when a continuous layer of oil has been formed. When the machine is at rest, this layer of oil is broken at the bottom. He tried to determine the same minimum point by resistance measurements, but could not get any consistent results, since the values of the resistances varied greatly. An investigation whether the sort of oil used had any influence did not yield any conclusive results, since no exact relations could be obtained. He sums up his experience in the statement that the electric resistance of the bearing may be very high in operation under special circumstances, but is generally very low.—*Elek. Zeit.*, April 14.

REFERENCES.

Equipotential Connections.—Müller.—The first part of an article in which he says that of the various means for counteracting the formation of sparks at the commutator, so-called equipotential connections have recently attained a greater importance. There are connections between points which should be at equal potential if the symmetry was complete. In case of dissymmetrical distribution of the magnetic field or of a non-uniform load in the different armature circuit, due to non-uniform transition resistances of the brushes, currents will flow in these equipotential connections so that the strain is taken from the brushes and the formation of sparks and overheating is prevented. The author gives a mathematical theory of the calculation of such equipotential connections in a special case.—*Zeit. f. Elek.* (Vienna), April 17.

Diagram of Alternators.—Niethammer.—With reference to Behrend's article on an experimental basis for the theory of the regulation of alternators, the author gives a description of a general three-phase diagram which he has used successfully for determining the regulation and other characteristic properties of the alternating-current machinery made by the Union Electric Company. Since the article consists only of diagrams and formulas it cannot be abstracted. —Lond. *Elec.*, April 15.

Surging of Alternators Connected in Parallel.—Sommerfeld.—The conclusion of his theoretical article. He gives the integration of his pendulum equation and considers the phenomena of resonance and interference. He then gives a numerical example and finally takes into account those points which he has neglected in his former more approximate calculations.—*Elek. Zeit.*, April 14.

France.—Liouville.—A statistical article on the import and export of dynamo-electric machines in France in recent years.—*L'Ind. Elec.*, April 10.

Differential Arc Lamp.—Von Zudnochowski.—A mathematical article on the behavior of movable cylindrical iron cores in double solenoids, with applications of the results to the theory of the differential arc lamp.—*Phys. Zeit.*, April 15.

Power.

Utilization of Peat and Lignite.—Wotherspoon.—An account of recent advances, made especially in Germany, in the utilization of the calorific value of peat and lignite. The output in 1902 of briquettes made from lignite in Germany was 12,438,000 metric tons; most of this fuel was consumed in the larger cities of Europe. The wholesale selling price of the briquettes in the larger German cities is between $2.10 and $2.25 per metric ton. The brown coal of Alabama has been briquetted by this process quite successfully and has been declared by the German experts to be superior to the best product from their own mines. It is also stated that remarkable advances have been made in Germany in the manufacture of fuel from peat by means of special mechanical processes. Fuel bricks are clean to handle and practically smokeless and have a calorific value between 8,500 and 10,000 B.T.U. per pound, while the thermal value of American bogs is said to range between 9,000 and 14,000 B.T.U. when bone-dry.—*Eng'ing & Min. Jour.*, April 7.

Electric Lifts for Blast Furnace Plants.—Schiebler.—An illustrated article on electric lifts for blast furnaces. With direct-current supply two motors with series parallel control are now generally used. The motors are compound-wound, the series winding giving a high proportion of the total field, so that at no load the speed is about 75 to 100 per cent. higher than at full load. A capacity of 120 to 140 hp is now often required for lifting ores. The author describes electric lifts built by two German companies. An automatic interrupter is provided for breaking the current at the end of the lift to prevent accidents in case of lack of attendance by the engineer, and this is done by means of a switch which does not interrupt directly the main current, but operates a relay circuit in which a small current flows. The latter passes through the magnet coils of a high-current switch, on the armature of which the high-current contacts are mounted. Since the armature is attracted instantaneously and also drops off instantaneously on account of its weight, switching is instantaneous. The lift for blast furnaces is mostly built with an inclined road, but a vertical lift is also described which is used as reserve. It is operated by a single motor. Since its capacity is 140 hp, the controller does not act directly upon the main current, but regulates small relay currents.—*Stahl und Eisen*, April 15.

REFERENCES.

Turbo-Generator.—An article giving the results of tests of a 900-kw turbo-generator recently installed in a German mine. The steam turbine is built by Brown, Boveri & Co., and is direct-connected to a 325-amp., 2,000-volt, three-phase dynamo with a power factor of 0.8 and a frequency of 50, and to a 110-volt, 105-amp. exciter. The number of revolutions is 1,500—*Glückauf*, April 16.

Mining Locomotive.—Perkins.—An illustrated article on the development of the electric mining locomotive.—*Sc. Am. Sup.*, April 23, 30.

Traction.

High-Speed Railways.—Peterson.—The first part of an article on the importance of the road construction for high-speed electric railways. The success of the experimental Zossen line of the German Studiengesellschaft has shown that to get a speed of 200 km. per hour with one car, a power consumption of 1,600 hp is sufficient. This shows that the pure cost of current remains within a limit which renders the financial success of such a road possible. However, the idea of sending single cars at short intervals over such a road, appears impossible on account of the prohibitive cost, since the consumption of 1,600 hp for a car of about 100 tons of weight, could not be covered by the receipts from about 80 passengers. If, however, a train of about 5 cars is used, the author estimates that 400 passengers, with a weight of train of about 250 tons, could be carried at a speed of 200 km. per hour with a power consumption of about 2,400 hp. In this case the current per passenger would be only three-tenths of that with single car operation. He thinks it would be preferable to make each car a motor car. In case the length of the train varies it would, then, however, be impossible to maintain the speed of the trains absolutely the same. While Reichel's arrangement of the three trolley wires, one above the other, has been shown to be an engineering success, he considers the great height to be a disadvantage. At street crossings the railway road would have to be carried above the streets. The whole construction of the road would be expensive. The most difficult question is, however, whether the construction of the track will be satisfactory for speeds of 200 km per hour. The results so far obtained on the Zossen road do not allow any decisive answer to this question. The problem is not whether the position of the rails is changed by a relatively small number of high-speed runs, but the real question is whether the road can be maintained continually in satisfactory condition without extravagant expense. He points out that for the Langen suspended railroad (as used in Elberfeld) the claim is made that the road is far superior to ordinary railway roads with regard to safety, to the possible speed and to the cost of maintenance. He estimates that with the ordinary track construction for a speed of 200 km. per hour, the smallest allowable radius of curve of the road would be between 2,500 and 1,600 meters. This seems to make the construction of such a road impossible within built-up districts. For a suspended road this condition does not exist. The article is to be continued.—*Elek. Bahnen.*, April, No. 8.

Storage Battery Traction.—Pallitsch.—A description of a storage battery car used on the suburban railroads of Dresden, Germany. The car has a capacity for 98 passengers and is provided with a battery of 184 double cells, each double cell having a capacity of 430 amp.-hours at a discharge rate of 140 amp. The average discharge voltage is 365. The cells are charged from a station connected to the Dresden tramway system, by connecting the cells in series, at an average of 480 volts. In order to charge the cells from a 120-volt circuit, the cells are connected in 4 parallel groups. The car is provided with four 360-volt, 27-hp series motors. The car weighs, without passengers, 44,000 kg. The speed is 45 km. per hour.—*Elek. Bahnen.*, April, No. 8.

REFERENCES.

Far East.—An article on electric railway development in the Far East. In spite of the large population there are now only six electric railways in operation outside of those in Japan. From a financial standpoint, the roads have been satisfactory, although the track mileage is very much smaller than that for cities of similar population in either Europe or America.—*St. R'y Jour.*, April 23.

Single-Phase Trolley.—Detailed descriptions of the method devised by the Oerlikon Company for collecting the current by means of a trolley from an overhead wire at the side of the road, for use on single-phase railways. The method has already been referred to in the Digest.—*Elek. Zeit.*, April 14; *St. R'y Jour.*, April 23.

Adjusting Car Resistances.—GOUGH.—A description of a practical method of adjusting the resistances of a K-10 controller, so that in going from one step to another the differences in the resistances will not be great enough to cause any violent shocks in car movement.—*St. R'y Jour.*, April 23.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Electricity on Board Ship.—LEBOND.—A continuation of his serial. In the present installment he discusses the installation of electric searchlights on battleships.—*L'Ind. Elec.*, April 10.

WIRES, WIRING AND CONDUITS.

Eddy Currents in Cable Sheaths.—FIELD.—The first part of a paper read before the (British) Institute of Electrical Engineers. Single-core cables designed for carrying alternating currents of any magnitude cannot be laid in separate iron pipes, owing to the strong alternating magnetic field which will be created in the mass of the pipe by the current and the hysteresis and eddy current losses consequent thereon. On the other hand, it is considered quite permissible to lay concentric or three-core cables (for three-phase currents) in iron pipes or troughs, for wherever there is included in the same cable both the "go" and the "return" conductors so that at every instant the algebraic sum of the currents within the pipe or trough flowing in either direction is zero, there cannot be any closed magnetic lines entirely surrounding that cable created by the currents within it. However, it would be wrong to believe that there is no external magnetic field produced by a three-phase current in a three-core cable; indeed, a very considerable field may exist giving rise to telephonic disturbances in neighboring circuits, eddy currents in the lead sheath or the iron pipe itself, and even earth currents. Similarly, if the "inner" so-called concentric cable be not truly concentric with the "outer," an external field will result, while if several concentric or three-core cables be connected in parallel at both ends, and for any reason the resistance of one conductor be unduly increased (e. g., through a bad connection), so that the algebraic sum of the currents included in this cable is not zero, not only will an external field exist, but there will be magnetic lines entirely surrounding the cable in question giving rise to losses if laid in an iron pipe. The author considers the external fields produced near single, concentric, three-core cables and the like, and investigates the losses occasioned thereby. In the special case of two lead-sheathed cables whose centers are separated by a distance of 12 in., the mean radius of sheath in each case being 0.587 in., he finds for a frequency of 60 and an effective current of 200 amp. that the mean effective e.m.f. in the sheath in volts per mile will be approximately 73 volts. Taking the cross-section of the sheath as equal to 0.46 sq. in., and the specific resistance of lead at 21 michrom, the sheath current will be 64.5 amp., representing a loss of 4.7 kw per mile length of cable. The paper is to be continued.—Lond. *Elec.*, April 15.

Calculating Networks.—MÜLLENDORFF.—The first part of a mathematical article on the rational calculation of distributing networks. The author starts from the case that a consumer is to be connected to one of two stations. In order to get a minimum of copper that station will be selected which is nearest to the consumer. If, however, there are other consumers between the two stations, the choice depends upon certain considerations. The author develops them mathematically and shows that before a distributing network can be calculated it is necessary to choose the position of the central station, and that this position must be taken into consideration when the different consumers are to be assigned to the various feeding points. After the position of the central station has been determined, it is possible to assign to each feeding point a certain district of action, so that all consumers within this district can be supplied more economically from this feeding point than from any other. He gives a method for calculating the network, so that the copper becomes a minimum. The article is to be concluded.—*Elek. Zeit.*, April 14.

Calculating Networks.—VERHÖCKX.—The first part of a highly mathematical article in which the author develops a method for the solution of the series of linear equations, to be solved in the calculation of closed network. It permits to proceed readily as well by analysis as by a purely graphical method. Another advantage claimed for this method is that it gives directly a general solution of the system of equations.—*L'Eclairoge Elec.*, April 16.

ELECTRO-PHYSICS AND MAGNETISM.

Magnetic Effect of Electric Convection.—SUTHERLAND.—An article pointing out that by the co-operation of Cremieu and Pender practically the whole of the difficulty in reconciling the apparently contradictory results obtained by various investigators concerning the magnetic effects of electric convection, has been traced to the one fact that Cremieu covered his metallic electrified surfaces with a solid dielectric. A solid dielectric rotating with a charged metallic disc reduces the magnetic effect considerably, so as in some experiments to make it appear to vanish. He refers to some theoretical investigations concerning electrolysis and shows that in ordinary electrostatics the displacement of the ether is not taken into account. It seems that the magnetic effect of electric convection is due to the slip between electricity and ether, and not to the relative motion of electricity and motor ether, although further experiments must be made in this direction.—*Phil. Mag.*, April.

Differential Method of Observing N-Rays.—MACE DE LEPINAY.—A description of a contrast method, by means of which a number of people who could not observe N-ray effects before have now been enabled to confirm them. The method is based upon Blondlot's observation that the impact of N-rays changes the distribution of the radiation from a sulphide screen, increasing it in a direction normal to the surface and diminishing it in a direction tangential to the surface. The author mounts two strips of sulphide close together, one of them being a narrow line 2 mm. thick, and the other a strip 25 cm. long, but inclined at an angle of 1° to the line of vision, so as to appear about the same thickness as the former. The two strips are mounted in such a manner that they appear to form the figure 7, the oblique branch being viewed normally. The strip viewed tangentially is made somewhat more luminous than the other, so that the two strips appear equally bright under normal conditions. If now they are simultaneously exposed to a source of N-rays, such as a sounding body, the strip viewed normally is seen to shine out, while the other darkens, and sometimes disappears altogether. It is possible, and even advantageous, to employ a luminosity much greater than that ordinarily used in N-ray experiments. The surface viewed tangentially must have a very fine grain. The best way of mounting the sulphide powder is to fix it by means of collodion or a rubber solution on a copper plate slightly roughened by an electrolytic deposit. Radiation from one surface to the other must be intercepted by means of a lead screen.—*Comptes Rendus*, March 28; Lond *Elec.*, April 15.

Dielectric Capacity of Atoms.—SUTHERLAND.—A theoretical paper in which he calculates the dielectric capacity of the ions on the basis of a theory formerly developed by him and by means of the mobilities of the ions, determined experimentally by Kohlrausch. He finds the law that the dielectric capacity of an atom is directly proportional to the valency and inversely proportional to the square root of the volume of the atom. The ionic velocity is then directly proportional to the square root of the radius. This explains the old paradox of ionic velocities. Hitherto it has been assumed that the ionic velocities have been measured by the same driving force for all ions. The result that a large ion like that of K travels faster than a small one, like that of Li under the same driving force in the resisting medium, seems puzzling, until, in taking account of the dielectric capacity of the atom, it is seen that the driving forces assumed equal are in reality not so at all.—*Phil. Mag.*, April.

Disintegration of Platinum Metals at High Temperatures.—HOLBORN AND AUSTIN.—An account of an investigation of the disintegration of platinum metals in different gases. Their results have a practical bearing on high temperature work in general. Platinum heating coils when brought too near the melting point of the metal are rapidly destroyed, and the case is still worse with iridium, which otherwise on account of its high melting point would be particularly suited for use in producing high temperatures. Some of their results indicate means by which the platinum metals may be protected from disintegration.—*Phil. Mag.*, April.

ELECTRO-CHEMISTRY AND BATTERIES.

Applications of Electricity to Metallurgy.—RICHARDS.—A lecture considering the mechanical, thermal and electrolytic applications of electricity to metallurgy. In the first class are the electromagnetic and electrostatic processes for dressing and concentrating ores. The thermal methods use the electric furnace, the chief features of which are first that heat can be generated up to 3,500° C., which is at least 1,500° higher than can be obtained in fuel-fed furnaces; secondly, the heat is applied internally in such close contact with the material to be heated that the efficiency is much higher than with the ordinary forms of heating. Electric heating will in general cost less if coal costs per ton over one-half of the price paid per electric hp-hour, without considering any other advantages of electric heating. The general principle on which Hall's aluminum process is based, is thought to be applicable for application to the reduction of many other metallic oxides; it is to dissolve the oxide in a solvent which is electrically more stable than the oxide.—*Technology Quarterly*, March.

Manufacture of Iron and Steel in the Electric Furnace.—NEUBURGER.—A review of the process of Stassano, Heroult and Keller. The opinion of Goldschmidt is quoted that the electric manufacture of special steels may compete in Germany with the ordinary method of making crucible steels. Gin is quoted as considering the following arrangement to be of nearly ideal perfection: it is the combination of the ordinary blast furnace for making pig iron, of the Bessemer converter for making the cheaper grades of steel and of an electric furnace for making fine steels, the electrical energy being obtained from generators coupled to gas engines which are operated by the waste gases from the blast furnace.—*Dingler's Polytech. Jour.*, April 2 and 9.

Ozonizer.—ELWORTHY.—A description of his ozonizer, which differs from the Siemens & Halske ozonizer in so far as the low temperature required for getting a sufficient yield of ozone is not produced by water cooling but by passing the air through the ozonizer at a high speed; the air is passed twice through a field of silent discharges. The apparatus is illustrated and the yield of ozone is said to be 60 to 70 grams per kw-hour, the concentration being 0.4 to 0.5 gram of ozone per cubic meter of the mixture of air and ozone.—*Elektrochem. Zeit.*, April.

Primary Cell.—BOUSFIELD.—A Faraday Society paper on a cell which consists of a central porous pot with nitric acid and a carbon pole, and of an outer vessel containing sodium hydrate solution and a metal pole, preferably of zinc. The best results are obtained with nitric acid with maximum conductivity—31 per cent. solution—and a sodium hydrate of maximum conductivity or of a strength slightly below this—a solution from 12 to 50 per cent. The e.m.f. is 2.6 volts at open circuit and as a special advantage of the cell it is claimed that it may be short-circuited far longer than most cells before it runs down. Various other metals, as substitute for zinc, and other acids, as substitutes for nitric acid, were also tested.—Lond. *Elec.*, April 15.

REFERENCES.

Electrolytic Rectifiers.—BURGESS.—A complete reprint of his paper on electrolytic rectifiers for charging storage batteries with alternating currents.—*Sc. Am. Sup.*, April 30.

Non-Aqueous Solutions.—DUTOIT.—A summary of our present knowledge of the electric conductivity, dissociation and other properties of electrolytes in solvents other than water, with an appendix giving a long list of papers on this subject.—*Jour. de Chimie Phys.*, February.

Ozone.—ERLWEIN.—The first part of an illustrated article on the Siemens & Halske system for producing ozone from air by silent discharges and utilizing the ozone for the sterilization of water. The application of the system in connection with German water works is described.—*Sc. Am. Sup.*, April 30.

Primary Cell.—HEINTZ.—An illustrated description of a primary cell in which the depolarizer may be regenerated when it is used up. For this purpose about one-eighth of the depolarizer is removed and a regenerating solution is added. No further details are given except the statement that the electrodes are zinc and carbon.—*Elektrochem. Zeit.*, April.

Determination of Latent Heats of Fusion.—GLASER.—A description of a calorimeter with an electric furnace for determining the specific heats of solid and fluid substances at temperatures up to 1,100° C. The author has used it for measuring the specific heats of lead, zinc, aluminum, copper and tin, and for determining the latent heat of fusion of these metals.—*Metallurgie*, March 22 and April 8.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Localization of Faults on Low-Tension Networks.—GROVES.—An illustrated paper read before the Birmingham Section of the (British) Institute of Electrical Engineers. His remarks refer particularly to a three-wire, low-tension network, with a neutral earthed at the generating station or sub-station through a resistance of two ohms. The more closely a network is "netted" the more troublesome it is to localize faults and from this point of view it is very desirable that each feeder should have its own defined network and be only linked to other similar networks where necessary for balancing and equalizing purposes. He considers it desirable, in addition to the feeder fuses in the station, to fuse at all points where it is found advisable to effect a function between the networks supplied by different feeders, and generally at these points only. The obvious danger of connecting two or more feeders through a distributor without fusing is that in the event of a short-circuit or bad fault, the faulty feeder fuse in the station may blow, and the "short" be fed through a small distributor of sufficient resistance to prevent another heavy feeder fuse from blowing immediately, but carrying enough current to overheat it and destroy it. The fuses at the interconnecting points can be comparatively light, because, if the system is properly arranged, the balancing currents will be small. During summer it is usually no disadvantage to work with many of the linking points

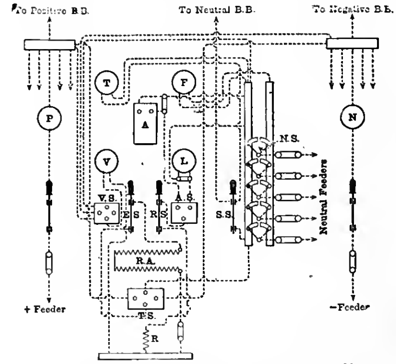

FIG. 4.—DIAGRAM OF TESTING APPARATUS.

open, which provides an excellent opportunity for overhauling the various networks. The neutrals, at points where fuses are inserted on the outers, will, of course be connected up solid. By the use of interchangeable blocks it is possible to fuse any line which may become an object of suspicion. The author describes the following tests which he has found convenient: *a*, observance of reading of recording ammeter permanently connecting the neutral to earth through a low resistance; *b*, join insulation test by Russel's method; *c*, checking polarity of fault by observance of feeder ammeter when "flashed"; *d*, detection of faulty feeder by "flashing"; *e*, partial localization by means of "transferring"; *f*, location by disconnection by shortest length. While these tests fail to indicate the exact position of the fault, final localization may be made by means of an interrupter and induction coil. Various methods of connecting the interrupter are illustrated by diagrams. Concerning Russel's test he says that this is most convenient for a rapid and frequent test. The formula is: $F = (V_2/c) - R$. In Fig. 4 R is the resistance in series with the recording ammeter, A (say 2 ohms), so that the test resolves itself into the reading of c on the ammeter, L, in series with or substituted for A at the time of testing and a momentary opening of the switch, RS, to read V_2 on the voltmeter, V. For moderately high resistances the value of R may be ignored. V should theoretically be of infinite resistance—i. e., electrostatic—but the results of this test are quite sufficiently accurate if any high-resistance voltmeter is taken. The author has experimented with a combined instrument which, if satisfactory, would replace V and L on the panel. The object of this instrument is to read F directly on an ohm scale when RS is momentarily opened. If the recording ammeter fails to notify any leakage and the test indicates that the insulation is "down," it is fairly safe to assume that the neutral is at fault, although occasionally a balance may occur.—Lond. *Elec.*, April 15.

REFERENCE.

Thermostat.—DARWIN.—A description, with detailed drawings, of an electric thermostat which was designed and first constructed as an adjunct to the spectrograph of the 24-in. refractor of the Royal Observatory at the Cape of Good Hope, the object being to maintain the prisms and other parts as accurately as possible at a constant temperature, day and night, over a considerble period. Two heating coils in oil are provided and a test of resistances is arranged like a Wheatstone bridge. Through its deviation from balance and the consequent deflections of a galvanometer the supply of current for the heating coils is controlled.—*Phil. Mag.*, April.

New Books.

VORLESUNGEN ÜBER TECHNISCHE MECHANIK. By Dr. Aug. Foppl. Leipzig: B. G. Teubner. 471 pages, 176 illustrations. Price, 10 marks.

The fact that the "Vorlesungen über Technische Mechanik" has passed through a complete edition within three years is a strong endorsement of its value. It is the second volume in a series of books upon technical mechanics adopted by the Hochschule in München, and, as its name indicates, is devoted to an exposition of the graphical methods of determining static strains. There are two methods adopted in works upon this subject. One deals with the matter entirely from the theoretical standpoint, which assumes forces acting upon bodies which may or may not, as the case may be, correspond to those which are met with in practice. The other method consists in taking existing structures and analyzing them to determine the relation between the forces and the structures.

Naturally, the present volume has adopted, according to the German fashion, the first method. It discusses at length the various theorems of the stresses produced in theoretical bodies by the application of hypothetic forces, and deals very little with the actual practice as encountered by the engineer in his every-day experience. To some this may appear something of a defect, but on the other hand the volume is replete with theoretical research. It contains numerous well-selected diagrams, which, if carefully analyzed and judiciously applied, will be a material aid to the engineer. As its name indicates, little symbolic analysis is used, but graphical methods are employed for everything so far as it is possible. Considerable attention has been given to the stresses in domes and similar roof structures, and an interesting graphical analysis is given of the stresses in an ordinary railway rail. Cranes and hoisting structures come in for a share of attention, but one misses many of the familiar bridge designs which are often seen in this country. Presumably the reader is expected to extend the principle's of the analyses given, to structures which do not receive specific illustrations.

STEAM BOILERS, THEIR THEORY AND DESIGN. By H. De B. Parsons. New York: Longmans, Green & Co. 375 pages, 155 illustrations.

In the preface to "Steam Boilers," Mr. Parsons states that it would be "almost impossible to write a work on the subject which could be considered original." In so far as the exhibition of data, which is new and unfamiliar, is concerned, the author is probably correct, but he has certainly produced a volume which is decidedly different from, and in many respects can make claim to originality over, previous text-books upon the subject. The preface further states that the volume comprises in book form a series of lectures delivered to the Senior Class of the Rensselaer Polytechnic Institute, and the students are certainly to be congratulated upon having their intellectual aliment present in so compact and consise a form, for it is rare to find a scientific text-book in which there is so little that is superfluous. In some respects there is apparently too much condensation, for unless one is prepared either by the perusal of previous treatises upon boilers, or has had considerable practical experience in steam engineering, there is much that might be incomprehensible.

The four opening chapters deal respectively with the physical properties of matter, such as the differences between liquids and gases, and the equations which govern the changes produced in a gas by variation of temperature and pressure; the laws of combustion and quantity of air supply, a classification and description of fuels, solid, liquid and gaseous; and the efficiency of furnaces.

Next comes a general chapter upon steam boilers, which in Chapter VI is succeeded by some pages upon chimney draught, which, apparently, would have been more logically located directly after the description of furnaces. Chapter VII detals with the materials used in boilers, describing and giving specifications for the various irons and steels which are employed.

Chapters VIII and IX take up boiler construction and are replete with matter of value to the designer and the draughtsman, but are almost too technical for a college text-book, excepting for those who intend to make a specialty of steam engineering. In Chapter X mechanical stokers are dealt with, but in an exceedingly brief and cursory manner, so much so as to hardly convey a fair idea of the value of mechanical appliances in firing.

The succeeding portion of the book is chiefly devoted to operation, discussing the questions of scale, corrosion and the testing and care of boilers. Chapters XIV and XV deal respectively with chimney design and smoke prevention, and apparently should have been included in Chapter VI upon chimney draught.

The typography of the volume is excellent; the illustrations are thoughtfully and carefully chosen, largely from actual working drawings, and include much practical information. The volume will take high rank as a brief epitome of modern boiler practice.

LUFTVERUNREINIGUNG UND VENTILATION. By Dr. Josef Rambousek. Liepzig: A. Hartleben. 244 pages, 48 illustrations. Price, 7 marks 50 pfennigs.

A somewhat free translation of the title of this pamphlet would be "Impure Air and Ventilation," and the author attempts to deal with the subject both pathologically and from the engineering standpoint.

The first 95 pages take up the theory of ventilation, showing some of the apparatus and machinery wherewith ventilation may be accomplished and the amount of air supply measured. In some cases, particularly when the author applies calculus to determine the amount of air pollution, the treatment appears to be a little forced.

In the next section the physiological effects of impure air are given considerable attention. Here mathematics are discarded and the work is purely descriptive. Finally, the last third of the pamphlet is devoted particularly to the description of the methods and appliances to be employed in ventilating factories and buildings in which there are many employees and wherein the avocations are such as to be particularly contaminative to the atmosphere, as for example such operations as matchmaking, the production of ammonia, the manufacture of nitroglycerine, and such of the textile arts as are likely to fill the atmosphere with lint or other organic particles.

The subject of air filtration is taken up and the various forms of screens and other methods discussed, although there appears to be no mention of the American device of washing air to effect purification.

As American literature is not overburdened with text-books and descriptions of ventilating appliances, this German exhibition will not encounter an overcrowded market and will, therefore be welcome.

GRUNDRISS DER REINEN UND ANGEWANDTEN ELEKTROCHEMIE. By P. Ferchland. Halle: Wilhelm Knapp. 271 pages, 59 illustrations. Price, 5 marks.

Of the 266 pages of the text, 234 are devoted to the discussion of electrochemical theory, and it may be said that here the author has taken great pains to be exact. He first discusses the theory of electrolysis. After some general remarks on electrolytic conduction, the author gives the laws of Faraday, the determination of the transport numbers of Hittorf, and the principles of conductivity. After a brief review of the theories of Grotthus, Clausius and Arrhenius he passes to the discussion of the relations between the theory of electrolytic dissociation, the gas laws and the modern theory of solutions. He gives the method for calculating the degree of ioniation from conductivity measurements, and finally gives Kohlrausch's law for the mobilities of ions.

The author then deals with the changes of energy in electrolytic processes He gives Thomson's rule and the Gibbs-Helmholtz equation for calculating the e.m.f. of an electrochemical process, and passes to Nernst's osmotic theory of electrolysis. Chapters on measurements of absolute potentials, on the electromotive behavior of non-metals, and on polarization conclude this part.

It must be acknowledged that these first parts of the book should be useful for the introduction into theoretical electrochemistry, since the author has taken care to state the theory exactly and fully, even in its most elementary parts, and to refrain from loose statements—which cannot be said about all elementary books on electrochemical theory. In a later edition the author would do good in adding references on the original papers since such notes on the literature of the subject would render his work valuable as a reference book. The arrangement of the theoretical part is logical, and after one has read the book over it is not difficult to find something in it.

The part on industrial electrochemistry comprises 30 pages, of which 13 are devoted to furnace processes, 11 to electrolytic processes and 5 to the generation of electrical from chemical energy. Even in these pages the author deals more with questions of theory, and the description of industrial electrochemical accomplishments is entirely inadequate. In a later edition the author should either leave out this part altogether or re-write it entirely and attempt to be complete up to a definite point.

PHÉNOMÈNES FONDAMENTAUX ET PRINCIPALES APPLICATIÖNS DU COURANT ALTERNATIF (Fundamental Phenomena and Principal Applications of Alternating Currents). By R. Swyngedauw. Paris: Dunod. 1904. Paper, 173 pages, 62 illustrations.

This is an elementary text-book of alternating-current principles. It is clearly and systematically written, but is intended for advanced students, since it employs algebra and elementary calculus.

The book is divided into an introduction and four parts, comprising nineteen chapters in all. The type is good, but the cuts are inferior. In some respects the book is well up to date, as, for example, in respect to the Cooper Hewitt converter; but in some other matters the treatment is archaic and very elementary.

ELEKTROMECHANISCHE KONSTRUKTIONSELEMENTE. By Dr. G. Klingenberg. Blatt 1-30, Apparate; Blatt 51-60, Maschinen. Berlin: Julius Springer. 36 tables, 114 illustrations. Price per installment, 2.40 marks.

This work will be completed in ten parts, of which Sections 1, 2, 3 and 6 are now issued. Upon the completion of the series, the author proposes to publish occasional supplementary numbers, as they are needed to maintain the series in harmony with advancement in design and construction. Each section consists of ten plates, 8 x 13 inches in size, with an index; the plates are unbound and contained in a convenient folder and envelope.

This publication presents a series of sketches which propose to the student and designing engineer the details of the elements of electrical design and construction. Unquestionably this series will meet the needs and desires of a large number of students and engineers. In masonry, steel construction and work of such character plates of this description have long been available; and recently hand-books for machine design have covered the same ground in their appropriate lines. In electrical construction there are yet difficulties in the way of the presentation of an adequate work of examples of design, from which the older lines of engineering are now free. There is still an absence of universality in electrical design, and much of modern construction is still hampered by the idiosyncrasy of the manufacturer.

Prof. Klingenberg has selected his examples from thirteen of the more prominent German manufacturers. It is a matter of surprise, in this connection, that these firms have been sufficiently broad and progressive to have permitted the use of their designs and drawings for general circulation. From this very cause, however, the work suffers its most marked limitation; the sketches are reproduced from assembly drawings: for the most part each device is given in elevation and plan, and there are few sections and details shown. While the drawings are dimensioned to a limited extent, the essential dimensions which student and designer alike would desire are not given—evidently for commercial reasons.

The series covers the entire field of approved electrical design. The selection of examples is judicious and fully representative. The plates are of a convenient size for use and are printed and reproduced with remarkable sharpness of line. They are, perhaps, too crowded in appearance, and their usefulness would have been enhanced had fewer sketches been placed on the plate, and these had been more intelligently arranged.

The series as a whole is an important contribution to the literature of electrotechnics, and will be useful to a large class of readers. It is to be hoped that it will suggest a similar work covering American practice.

Climax Arc Lamps.

A new form of enclosed arc lamp herewith illustrated and described has been brought out under the name of "Climax" by the Keystone Electric & Manufacturing Company, Allegheny, Pa. The cuts, Figs. 1, 2 and 3, show it complete and in detail. A special feature shown in Fig. 1 is the regulating coil made by machinery designed for the purpose. A flat copper strip is wound spirally about a solid mica core and each layer of the spiral is separated from the adjacent layer by mica washers. The spiral is then surrounded by another mica tube, and all is encased in a metal tube, with metal heads, to which are fastened the necessary terminals and a clamping device to adjust the coil with. The whole forms a solid indestructible fire-proof coil. Fig. 2 is a view of the mechanical movement of the lamp, with the dash-pot and the flat spiral connectors, the latter being regarded as a decided advance in current-carrying devices for such work.

FIG. 1.—REGULATING COIL.

The upper carbon holder and the carbon-carrying tube have but one motion and cannot be turned, avoiding disarrangement of the spiral conductor during operation. In the direct-current lamp the dash-pot is constituted with a loose-fitting piston of large diameter in the gas diffusing chamber. This piston is fastened to the clutch

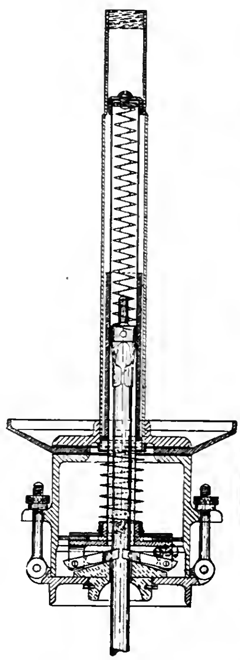

FIG. 2.—DASH-POT MOVEMENT.

FIG. 3.—ENCLOSED ARC LAMP.

plate in such a manner as to have a lateral motion, thus permitting it to find its own free path and avoiding all possibility of wear and sticking, due to friction.

The enclosing globe cap forms the bottom of the gas-diffusing chamber and dash-pot, and carries the indestructible insulating bushing and negative carbon support. It is held in place by two outwardly-swinging arms engaged by two lugs on opposite sides of the gas chamber, and fastened by thumb nuts. This feature in connection with the sealed tube in which the armature operates furnishes a perfect enclosure with resultant long burning of 200 hours. The clutch is composed of two cast-iron parts—duplicates—hung on two cotter pins in such a manner that when they fall toward each other the opening becomes less than the diameter of the carbon. Hence, when the clutch plate is raised they grip the carbon securely.

The porcelain resistance holder has a thread moulded on its outer surface, in which the wire is carefully wound. A special clamping device is placed to one side with a sliding member, by which the adjustment for proper arc voltage is achieved. The company will also furnish an external resistance, in a separate case, for 220 to 250-volt lamps, which may be placed at any convenient point; or the lamp may be suspended from it. A switch is provided in the top of the lamp to cut it out of circuit when burning; and will be found to do its work effectively, breaking 250-volt circuit, without any perceptible arc.

The housing, with its colonial design, has a pleasing appearance. It is made of copper and riveted, no solder being used on any part of the lamp. The outside globe holder is fitted to an internal sleeve of the main shell by three bayonet locks, and is easily removed or replaced. Housings of steel or brass can be furnished, if so desired. The inner globe is of large diameter, allowing the whole hand to enter for cleaning. It is of the closed end type, and is readily removed and replaced, when trimming.

1,500-K. W. Alternator for St. Louis.

Following is a description of a National alternating-current generator to be installed at the central power station at St. Louis. This alternator will be direct-connected to a 2,250-hp Hamilton Corliss vertical cross-compound engine. The rated output is 1,500 kw, 25 cycles, 6,600 volts, running at 83 r.p.m., and the current generated will be used for various purposes.

Like all standard alternators built by the National Electric Company, it is of the revolving field type, thus leaving the armature stationary and easily accessible, and the difficulty of properly insulating the armature coils is eliminated as the windings are not subject to any mechanical strains whatever. The revolving field is of large diameter, giving additional fly-wheel effect to the engine, and the construction of the field coils makes them practically indestructible. All parts are accessible and the method of ventilation insures low temperatures.

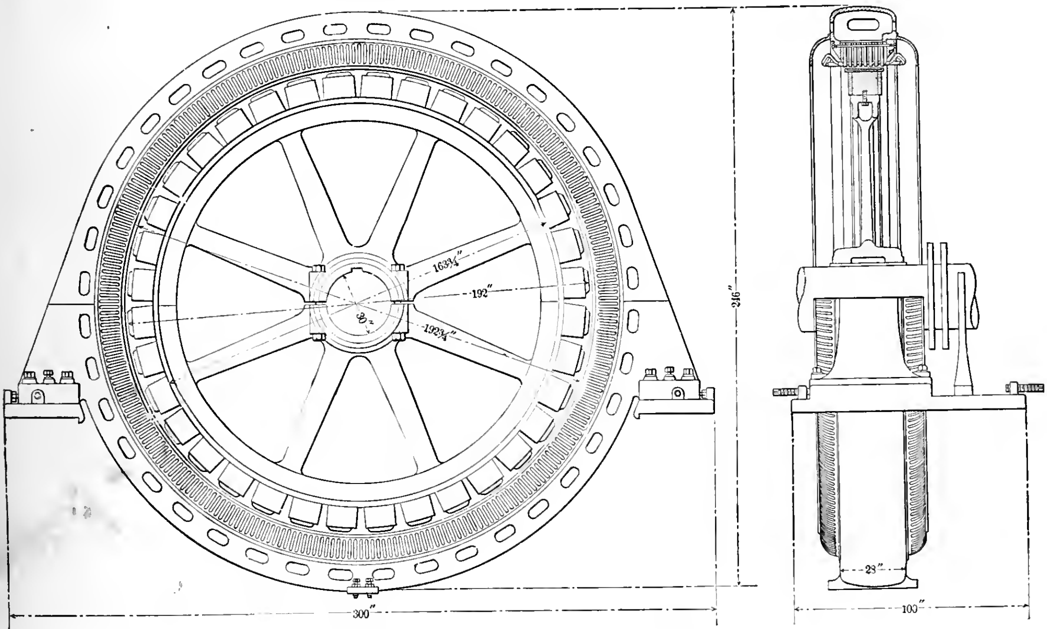
The revolving field is made up of cast steel in halves, which are bolted and secured together by shrunk links. The rim of the wheel is of channel cross-section to which the cast-steel pole pieces are bolted. The field coils comprise 65 turns of 1½ x ⅛-in. copper strap, wound on edge and thoroughly insulated, the outer edge of the coil being exposed to the atmosphere for cooling. Laminated pole shoes are secured to the ends of the pole pieces and serve to hold the field coils in position. These shoes cover a large polar arc, distributing the magnetic flux evenly.

The field coils are insulated from the pole pieces by fuller board, and from the pole shoes and spider ring by heavy fibre. The revolving field is 16 in. in diameter and weighs approximately 50,000 pounds.

The frame is a circular cast-iron housing into which laminated punchings with inwardly projecting teeth are assembled, for the reception of the armature windings. The frame is extremely heavy and stiff, not requiring any external support, and is divided horizontally, the halves being firmly bolted and keyed together. Bolts and keys are contained entirely within the cross-section, obviating the use of side lugs. Large open spaces are provided in the sides of the frames, allowing a free passage of air from the ventilating ducts in the core.

The armature core is built up of laminated soft steel punchings, being annealed and japanned before assembling; ventilating space blocks are inserted at suitable intervals, providing openings extending around the circumference and allowing a free passage for the heat generated in the windings. There are six slots per pole, 2½ in. deep by 1½ in. wide, each being wound with 14 conductors of .37 by .28-in. compressed copper strand. The external diameter of the armature is 16 ft. ¾ in. and the width of the core 16 in.

Cast-iron collector rings and carbon brushes are used, enabling the machine to be operated with a minimum amount of attention and at the same time providing a collector gear which will carry a heavy temporary overload.



ELEVATION AND SECTION VIEWS OF 1,500-KW ALTERNATOR.

The net weight of this alternator is 135,000 pounds, and following are the guarantees on this machine:

Efficiency—1¼ load, 95.5; full load, 95.5; one-half load, 94.75. Regulation—0.5 per cent. on power factor, 1; 22 per cent. on power factor, zero. The temperature will not exceed 30° on the armature and magnets on a continuous run at full load and 40° on the armature and magnets on a continuous run at 25 per cent. overload. This generator has been built by the National Electric Company, at their Milwaukee (Wis.) shops.

A Circumferential Velocity Indicator.

We illustrate herewith an interesting speed indicator, known as the "Cut-Meter," and manufactured by the Warner Instrument Company, Beloit, Mich., which is particularly useful in determining cutting speeds in machine tool work. The radical feature is that instead of being actuated by gearing there is an Arago disc arrangement whereby a revolving magnet imparts a torque to a disc connected to the indicating dial pointer. The instrument is a combination of a tachometer and a wheel, the calibration being such that every foot traveled by the circumference of a wheel bearing on the revolving surface, the circumferential speed of which is to be determined, registers one foot upon the dial. If the wheel is 6 in. in

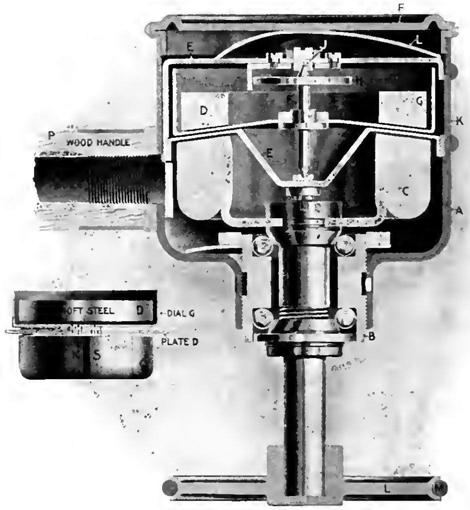


FIG. I.—SECTIONAL VIEW OF CUT-METER.

circumference, for example, two revolutions of the tachometer shaft will be required to indicate one foot on the dial, so that it is only necessary to properly calibrate the instrument in order to get a direct reading in feet per minute.

Referring to the accompanying illustration, Fig. 1, the magnet, *c*, is carried by the ball bearing, *b*. The outside is threaded and screws into the outer case, *a*. The ball bearing is secured by a spring washer and is finally adjusted at the factory. In front of the magnet is a soft steel ring, *d*, which deflects the lines of force through the aluminum disc, *g*. This disc is mounted on a hardened steel shaft and supported by the jewels, *j*. On the outside edge of the aluminum disc are engraved the fingers indicating the speed. Also attached to this shaft is a hair spring, *h*, so adjusted that it resists the turning of the aluminum dial and brings it back to the zero point when the magnet is at rest. The jewel bearings and the steel ring are carried by the inner case, *e*, which telescopes into the outer case and can be removed at will. The inner case also serves the purpose of protecting the dial, *g*, from the air currents set up by the magnet when revolving. Through both outer and inner case is an opening covered by a glass, *k*, through which the figures on the aluminum dial can be read. Attached to the main shaft is the driving wheel or disc, I, of proper diameter, having a grooved periphery, into which is snapped a miniature rubber tire, *m*.

Fig. 1 illustrates the arrangement of the poles on the permanent magnet. The lines of force flow from the north pole through the aluminum dial, *g*, to the steel plate and back again through the dial to the south pole of the magnet, *c*. When the magnet is revolved it sets up a dragging or accessory action in the dial, *g*, this action or rotation being in proportion to the speed of the magnet; and as the hair spring is subject to the same law, it is evident that increasing the speed of the magnet will increase the displacement of the dial in exact proportion. The dial or scale can, therefore, be marked by equal divisions from the lowest to the highest reading. Since adjusting the magnet closer to the steel ring increases the torque or dragging effect, it is only necessary to select a hair spring of proper stiffness, to revolve the magnet at a known speed, at the same time adjusting the ball bearing until the scale indicates the correct speed. The instrument will then be accurate on the entire range of the scale and will remain so permanently, there being no necessity for subsequent adjustment or recalibration.

As there are no mechanical connections between the magnet and the indicating dial, and as the magnet runs very easily (there being always an abundance of power to drive it), there can be no inaccuracy up to this point.

The indicating dial is mounted on a steel shaft, the points of which are hardened and supported in sapphire jewels, practically eliminating all friction or retardation. How perfectly this is accomplished can be judged from the fact that a change in speed of one-fifth of 1 per cent. is shown on the dial. Since the dial and shaft are very light, the strength of the jewels and pivot is great in comparison to the weight, and experience has shown that they will stand indefinitely the regular service likely to be given in any ordinary machine shop.

Fig. 3 shows a "cut-meter" complete, full size. The instrument is sufficiently small and light, so that it can be carried in the pocket without inconvenience. It presents a very handsome appearance, being substantially constructed of brass and nickel-plated. The handle is turned from a hard tropical wood and is highly polished.

The material of the ball bearings is a superior quality of soft steel, which is first finished to shape and then case-hardened. Each

FIG. 2.—THE CUT-METER IN USE.

piece is ground on a specially-constructed machine, so that every part may be true and in perfect alignment. After being ground, each part is carefully tested, and imperfect or soft pieces discarded.

Fig. 1 shows the details of bearings. In a test several of the bearings were run at a speed of 15,000 r.p.m. for a sufficient length of time to equal several years actual work on the instrument; at the end of this crucial test, the bearings were found to be in as perfect condition as before.

The magnet is practically permanent under all conditions. The air-gap is only about 1/32 of an inch, or about one-half of 1 per cent. of the entire length of the magnet. This narrow air-gap effectually prevents the instrument from being influenced by outside magnetic forces, and the strongest field does not affect its accuracy in the slightest degree. The steel used is of a special quality and is made to order. The pieces are first hardened, then magnetized, and then aged by a process which prevents further change in strength. They are carefully tested and laid aside for a considerable interval before being retested. This test is so delicate that a change too slight to be appreciable in actual work is at once detected.

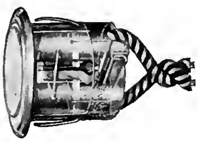
This meter is of particular value to the machine shop manager, for by its use he will probably find in a large majority of tests made that the working speeds in his shop are from 25 to 50 per cent. lower than they ought to be in order to obtain the most profitable results. In a factory recently inspected, equipped with a multi-voltage drive, one tool was found running on soft steel at a speed of 150 ft. per minute, while the average speed throughout the entire factory on the same stock was about 24 ft. On another occasion, of two boring mills inspected of the same make working on the same stock, the speed of one mill was 150 ft. and the other 22 ft., the cut

FIG. 3.—CUT-METER, FULL SIZE.

and feed being practically the same in both cases. With the use of an apparatus such as that described there is no guesswork, since it indicates the cutting speed instantly, accurately and with a dead-beat register. The meter is available for a number of other uses besides determining the cutting speed of machine tools. When held on the outside of a paper mill dryer it instantly indicates the exact speed at which the machine is making paper. It can also be applied for determining the speed of elevators, since it is not necessary with it to make any calculations, and at the same time indicates when the elevator car is traveling at its maximum speed.

Screwless Electrical Fixtures.

A novel departure in the method of connecting wires to appliances has been made in the "Noscru" midget push button, manufactured by the Sarco Company, No. 906 Sixth Avenue, New York City. The circuit wires are simply threaded through the rubber bottom of the button, bent over, and by one twist the button is ready to set in position. A yielding plunger of phosphor-bronze makes a direct wiping contact on the wires, thus obviating the necessity of using screws, clips or other fastenings; and it takes less than ten seconds to connect the button, without the use of tools. The illustration readily explains the method to the practical electrician.



SCREWLESS PUSH BUTTON.

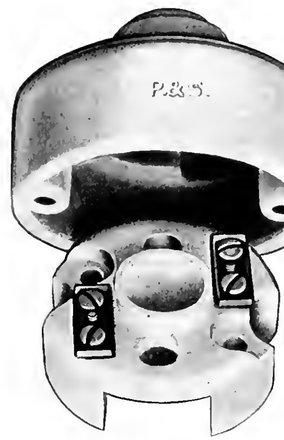
One of the chief features of the Noscru button is that it can be taken apart by bending the two pins at the bottom in a vertical position and the inside part falls out. It can be engraved or stamped and inserted again and made fast by two ordinary pins.

The Noscru midget push is made in standard sizes, while the Pee-Wee takes a No. 18 wire, and yet is really the smallest button in the world. The "Pee-Wee" fits a 3/8-in. hole, and can, therefore, be used in many places to a greater advantage than anything else of its kind on the market. The Noscru button has the contact concealed in the rubber body and therefore is readily adaptable for any kind of exposed work, such as outside door plates, marine work, etc.

The makers inform us that they have had the Noscru button under a perfect test for three years, and that it has never failed to work. The Sarco Company promise a Noscru key arm switch in a few weeks which will have the same advantages in itself as the Noscru button, for the purposes for which it is intended.

Fuseless Rosette for Concealed Work.

We illustrate herewith a new fuseless rosette for concealed work, which has just been placed on the market by Pass & Seymour, Inc., at Solvay, N. Y. It embodies a number of neat features. The bot-

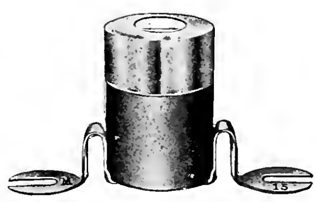


FUSELESS ROSETTE.

tom of the base is recessed to permit the heads of tubes to extend half an inch from the ceiling, and it covers them up completely. A closed porcelain cover then slips over the whole, with perfect concealment, making a very finished and complete installation. The material used is of the high grade with which the manufacturers' name has so long been associated, while the finish and smoothness of the rosette are in every way admirable. The trade is supplied with this device from headquarters or from the various branch offices.

New Form of Fuse.

A new fuse that has just been introduced by the Horton-Massnick Company, of Detroit, Mich., is herewith illustrated. The fuse is especially for set-screw contacts with centers which engineering practice has established. Both terminals are flexible and will take any centers from $1\frac{3}{4}$ in. to 3 in. The fusing material is formed in the shape of the letter U and is entirely surrounded by finely divided refractory material, with the exception of a very short portion, which



NEW FUSE.

is exposed to view through a hole in the bottom of a brass cap, which seals the open end of the fuse case or tube.

The hole in the brass cap is covered by a transparent disc and the fuse is so constructed that the fusing material will blow exactly under this window. The user can determine at a glance whether or not the fuse is blown, because he can see the fusing material itself or the blackened window resulting from the blown fuse. The fuse is designed for 250-volt work and can be furnished in capacities from 1 to 30 amp.

A New Testing Set.

Machado & Roller, the selling agents of the Whitney Electrical Instrument Company, are marketing a new form of testing set, illustrated in Figs. 1 and 2 herewith. It is of the decade pattern, in which the drawbacks incident to the great number of plugs necessitated by the old post-office form of construction are eliminated, there being but four plugs in the rheostat itself. It will be noticed that

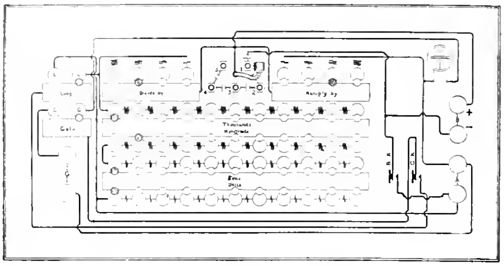


FIG. 1.—DIAGRAM OF CONNECTIONS.

the use of reversing blocks in the bridge arms has been done away with by adding an extra coil to each arm. This expedient eliminates two plugs and makes the operation of the set much more easy to understand. The keys are of a novel form which can be operated independently or like the conventional combination key, whichever is desired. Five large dry cells are built into the containing case and a flexible cord with plug is arranged so that any number of them can

FIG. 2.—GENERAL VIEW OF TESTING SET.

be used at will. An ingenious modification of the ordinary construction of decade and post-office sets is used to shift the internal connections from those employed in making ordinary resistance measurements and the Murray test to the connections for the Varley test, so that the two "X" posts common to every bridge are the ones to which the outside line is always attached no matter what test is being made thereon. A pair of binding posts to which an external galvanometer of the reflecting form may be attached for high sensibility work is also provided: and by shifting one plug, either this external galvanometer or the one that is built into the set is brought into play. Another pair of posts allows of the use of an external source of e.m.f. where this is desired. Instead of following the conventional procedure of marking the ratio arm blocks "A" and "B," they are stamped "Divide by" and "Multiply by," respectively. The connections are such that, when a plug is inserted in the gap between the "divide by" block and any one of the four circular blocks opposite thereto, the readings as indicated by the position of the plugs in the rheostat are to be divided by the number stamped on the circular block to get the correct reading. Similarly, the resistance plugged in the rheostat is to be multiplied by the number indicated by the position of the plug in the "multiply by" ratio arm block. The plug blocks for changing over the loop and galvanometer connections are marked with similar clearness, so that practically any one can use the bridge without chance of confusion. The actual diagram of connections is as shown by Fig. 1.

An accuracy of adjustment of a tenth of one per cent. throughout is claimed, and it is also stated that the galvanometer is sufficiently sensitive to give a marked deflection with a tenth of a per cent. resistance variation when working with full battery power on a resistance of moderate value. The galvanometer is not affected by external fields and can be used with the set in any position. It is thought that a moderate-priced set having the above characteristics will meet with considerable favor from a large class of users.

Sheet Metal Stamping Press.

A machine tool of large utility in the electrical field is the sheet metal stamping press, and we illustrate herewith the 1904 type brought out recently by the Perkins Machine Company, of South Boston, Mass. It weighs 1,275 pounds, is made with jigs throughout, and has each part interchangeable. The shaft is of large diameter and supported by large bearings bored out from the press body. The clutch is of special design, giving a high rate of speed, from 50 to 300 revolutions. There are three shelves which can be detached from the machine. One shelf is for the screw driver, oil can, wrenches, etc. The other shelves are to receive tin, one before stamping, and after stamping the scrap is thrown on the other shelf. This makes the

STAMPING PRESS.

press fire-proof, and does away with the combustible boxes and other matter that accumulates under the press, inasmuch as every manufacturer who uses a press is obliged to have a table of some kind to put the scrap on.

The Perkins Machine Company makes over 200 varieties of press, from those for light jewelry work to presses that stamp out battleship plates. The hermetically-sealed steel caskets are made on them, as well as the well-known Oneida steel pulley. The parts for the Edison storage battery are made on these presses, and even the small mica washers so familiar in electrical goods are made in quantities on Perkins presses in North Carolina.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Dullness prevailed in the stock market and speculation was quiet, there being an absence of outside interest. Unfavorable railroad earnings, the quietness of trade and uncertainty regarding crop prospects, with the unsettled situation in the Northern Securities matter, all contributed to this end. Money was exceptionally easy; in fact, it was a drug on the market and prices for it were low. During the week Metropolitan Street Railway placed a loan for $2,500,000 on short-term notes at 5 per cent. There was no movement of any consequence in the standard stocks, but in the Steel shares there was some activity, preferred receding somewhat on the pessimistic reports as to iron and steel trade. In industrials nothing of a noteworthy character occurred excepting the rise in gas stocks, although Rubber preferred held its own on the resumption of dividends. The curb market dwindled to small proportions, and was without feature except for a rise of nearly 20 points in Brooklyn Union Gas 6 per cent. convertible bonds on sales of $120,000. Some of the copper stocks are a little higher, and Interborough Railway advanced over 2 points. Electric and traction stocks are all lower than a week ago, the greatest decline being 4¾ in General Electric, Allis-Chalmers preferred and Westinghouse common following with 3 points each. All three of these stocks closed at the lowest prices of the week for each, namely, General Electric, 159¾; Allis-Chalmers 40 and Westinghouse 155. While the tractions were weak they did not lose quite so heavily as the electric stocks above named, although they too closed at the lowest figures. Brooklyn Rapid Transit closed at 46¼, being a net loss of 1¼, and Metropolitan Street Railway 112¼, a net loss of 1⅞. Following are the closing quotations of May 3:

SAN FRANCISCO GAS AND ELECTRIC COMPANY makes the following report for the year ended December 31, 1903:

	1903.	1902.	Changes.
Total income	$2,504,771	$1,989,834	Inc. $514,937
Operating expenses	1,534,814	1,285,897	Inc. 248,917
Net	$969,957	$703,937	Inc. $266,020
Depreciation, etc., funds	395,000	282,101	Inc. 112,899
Balance	$574,957	$421,836	Inc. $153,121
Dividends	396,211	....	....
Surplus	$178,746	....	....

Net profits and consumers for the last four years follow:

	1903.	1902.	1901.	1900.
Net profits	$969,957	$703,937	$458,440	$675,556
Consumers Dec. 31:				
Gas	65,710	35,791	34,271	30,800
Electricity	9,771	5,238	4,286	2,325

NEBRASKA TELEPHONE COMPANY.—The Nebraska Telephone Company reports as follows for the year ended December 31, 1903:

	1903.	1902.	1901.
Gross	$1,049,907	$905,660	$754,971
Expenses	857,310	737,220	617,345
Net	$192,597	$168,440	$137,626
Dividends	115,768	99,000	81,222
Surplus	$76,829	$69,440	$56,040

SAO PAULO LIGHT & POWER.—The Sao Paulo (Brazil) Tramway, Light & Power Company, in which Canadian and American capital is interested, reports as follows for the year ended December 31, 1903, Canadian currency equivalent:

	1903.	1902.	1901.
Gross Railway Company	$962,941	$879,907	$630,282
Gross earn. Light & Power Co., etc.	340,234	243,378	119,394
Total gross	$1,303,175	$1,123,285	$749,676
Expenses (both)	403,747	417,916	486,719
Net	$899,428	$705,369	$262,957
Charges	286,885	250,000	....
Surplus	$612,543	$455,349	$262,957
Dividends	391,379	239,019	....
Surplus	$221,164	$216,350	$262,957

PITTSBURGH TROLLEY YEAR.— The Pittsburg Railways Company in its report for the year ended March 31, 1904, shows gross $8,661,394, net income $3,612,169, deductions and fixed charges, $3,628,246, leaving a deficit of $16,077 as against a surplus last year of $1,152,251, out of which $870,000 was paid in dividends. The traffic statistics are as follows:

Passengers carried	174,400,055	164,407,446	Inc.	9,992,609
Car mileage	34,748,836	33,577,214	Inc.	1,171,622
Earn per car mile	25.32c	24.65c	Inc.	1.07c
Exp. & tax per car m.	14.92c	14.33c	Inc.	.59c
Net per car mile	10.40c	10.32c	Inc.	.08c

The company's business was seriously affected by the hard winter with respect to lower receipts and higher operating expenses. It built 34.53 miles of new track and bought 200 cars.

STANDARD UNDERGROUND CABLE COMPANY shows as follows for the year ending December 31, 1903:

Gross	$8,685,294
Material on hand	507,325
Total	$9,192,619
Exp., disc., factory cost, etc.	8,488,181
Net	$704,438
Dividends	229,732
Surplus	$474,706
Previous surplus	754,407
Total	$1,229,113

MICHIGAN TELEPHONE DIVIDEND.—The Michigan State Telephone Company has declared a quarterly dividend of 1½ per cent. on the preferred stock, payable June 1 to stockholders of record May 1. Detroit Telephone bondholders participate in this dividend, as under the settlement they got $480 in bonds of the Michigan State Company, $206.25 preferred stock and $428.75 common and $2.50 in cash, in lieu of January interest, on each $1,000 Detroit Telephone bond. A voluntary payment of some kind will be made to minority stockholders of Michigan Telephone Company when other matters are cleared up.

BELL TELEPHONE STOCKHOLDERS.—The following figures will show the number of stockholders of the American Telephone & Telegraph Company.

Jan. 1	Amt. capital stock.	No. shareholders.
1903	$87,836,100	10,802
1904	127,068,900	15,743

Since January 1, 1904, the number of shareholders has increased over four hundred.

THE NEW ENGLAND (BELL) TELEPHONE AND TELEGRAPH COMPANY reports as follows for the year ended December 31, 1903:

	1903	1902.	1901.	1900.
Gross	$6,092,865	$6,024,610	$5,177,412	$4,518,396
Exp. & tax	4,677,726	4,855,841	4,139,930	3,621,644
Net	$1,415,139	$1,168,769	$1,037,482	$896,752
Dividends	1,297,002	1,108,726	947,406	838,635
Surplus	$118,137	$60,043	$90,076	$58,117

MARCONI WIRELESS.—At a meeting of the directors of the Marconi Wireless Telegraph Company of America, John D. Oppe was elected second vice-president and general manager, vice William H. Bentley, resigned. Mr. Bentley remains a member of the board and will continue his interest in the affairs of the company. Mr. Oppe is also general manager of the Canadian Marconi Company.

NEW YORK METROPOLITAN.—Kuhn, Loeb & Company have purchased $2,250,000 Central Crosstown Railroad Company 2-year 5-per-cent notes, secured by bonds of that company, which are guaranteed by the Metropolitan Street Railway Company.

Commercial Intelligence.

THE WEEK IN TRADE.—There are signs of improvement in trade, and with the advent of the belated spring weather it will no doubt be realized. At most markets distribution is quiet, and trade for April, the country over, does not equal that for the same month last year. In the northwest, conditions are somewhat improved and business has been helped by the more seasonable weather. Pacific Coast trade and crop advices are better than of late, and while weather and crop conditions are backward in the South the outlook for the future is very hopeful. Collections are still backward, though some improvement is noted at centres where the weather has permitted a better distribution of goods. Among the industries the demand for pig iron is rather dull. Finished products are quieter, but it is pointed out that the demand for the smaller products is inducing a production of steel not much below the high record of a year ago. Export trade is expanding, thus removing the fear of a burdensome surplus of products. The demand for building materials is improving with the better weather conditions, and cessation of strikes, special activity being reported at Western cities and on the Pacific Coast. In short, trade in general reflects the weather conditions, improvement being reported from some localities, and stagnation from others. The business failures do not appear to exceed the normal number, the aggregate for the week ending April 28, as reported by Bradstreet's being 197, against 199 the week previous and 173 the corresponding week last year. The copper market continues dull, although it is stated that some good-sized orders have been placed during the past few days for electrolytic and casting copper by wire and brass makers. Holders of the metal, however, are firm in their views as to its market value and are not disposed to make any concessions. Lake stiffened ¼c. during the week, closing officially, at 13⅜c. @ 13⅝c; electrolytic 13⅛c. @ 13¼c.; casting stock 12⅞ @ 13⅛c. The London market has advanced.

CAMPECHE TO HAVE ELECTRIC LIGHT.—Campeche, capital of the State of Campeche, Mexico, is to have an up-to-date Yankee electric lighting plant. A concession has already been granted by the State authorities which sanctions the construction and operation of the system for a period of twenty years. The franchise was originally made out in the name of Jose de las Munecas Zimavilla, a prominent Campeche lawyer, who has made over the permit to a joint stock company, which has been organized under Mexican laws, with a capital of $150,000. W. E. Herrmann, of Mexico City, is largely interested in the enterprise. The electrical expert who will have charge of the construction and equipment of the Campeche plant is A. A. Chaillet, at present located in Mexico City, at one time technical director of the Shelby (Ohio) Electric Company. He is now managing director of a company formed last year in Mexico for manufacturing incandescent lamps. The initial capacity of the Campeche plant will be 40 arc and 2,000 incandescent lamps.

THE FIBRE CONDUIT COMPANY, of Orangeburg, N. Y., find that between March of 1903 and March of 1904 their business increased near 300 per cent., and that during that period they had the most successful year in the history of the company. The most successful month they have experienced was April, 1904. Among their recent orders for conduit, which orders have been shipped in carload lots or nearly so, were those for the Edison Electric Illuminating Company, of Brooklyn; Citizens' Telephone Company, of Grand Rapids, Mich.; Merchants' Heat and Light Company, of Indianapolis; the Boston Edison Company; the Detroit Edison Company; the Suffolk Light, Heat and Power Company, of Southhampton, L. I.; the General Electric Company; Westinghouse Electric and Manufacturing Company, and the United States Naval Academy at Annapolis.

BUFFALO FORGE ORDERS.—The Buffalo Forge Company, Taylor Building, Cortlandt Street, has secured contracts from the Lehigh Valley Railroad for a big lot of exhaust fans, etc., which will be electrically operated. For the forge shops at Sayre, Pa., two 10-ft. exhaust fans and four No. 11 blowers have been ordered. The fans are to be belted to motors of 50-hp capacity each and the blowers will be direct-connected to 30-hp motors. For the locomotive shops, ten 10-ft. fans have been ordered. These fans will each be driven by 20-hp motors. The American Malting Company, New York, has ordered a 40-hp Buffalo engine for direct connection to a Westinghouse generator.

STEEL BY ELECTRICITY.—The government commission sent to Europe by the Canadian Government to investigate the electro-thermic processes employed in the smelting of iron ores and the making of steel has returned. It is reported from Toronto that the commission has found the process feasible and reports that steel can be produced by the electro-thermic process at a total cost of $8 per ton. This is taken to mean that the smelting of iron ores by electricity is commercially feasible in Canada and that the development of Canada's water power and iron deposits is a thing of the near future.

OLD EQUIPMENT TO GO TO CUBA.—The old equipment in the Central Building, 143 Liberty Street, consisting of six United States Electric belted generators and three Westinghouse engine aggregating about 200-kw capacity, is to be shipped to C. H. Thrall & Co., engineers and contractors, Havana, Cuba, in which firm J. P. Hall, the electrical contractor, is interested. The new plant to be put in the Ceneral Building, the contract for which Mr. Hall has secured, will be of 300-kw capacity and will consist of three 100-kw C. & C. generators direct-connected to Ball & Wood engines of 150-hp capacity each.

HAVANA LIGHTING PLANT ENLARGED.—A reorganization scheme is contemplated regarding the Spanish-American Light & Power Company Consolidated, which holds the exclusive franchise for lighting Havana and Matanzas, Cuba. Mr. Hayward, of the Baltimore gas plant, engineering and contracting firm of Bartlett, Hayward & Co., is president of the company. It is planned to reduce the capital of the company and to incorporate the concern under Cuban laws. The plant at Havana will be considerably enlarged. M. Jiminez is the electrical engineer of the company.

LAMP POOL.—Another meeting of the incandescent lamp manufacturers is, it is said, to be held in Cleveland this week, again bringing together the working forces of the National Electric Lamp Company and the "Independent" companies. The purpose of the meeting has not been divulged, but it is presumed to be for the purpose of further adjusting the agreement entered into at the meeting of the same parties held at the Manhattan Hotel a few weeks ago. The action of the "pool" are being watched with great interest.

MOTORS FOR CENTRAL AMERICAN MINES.—The Mine and Smelter Supply Company, 139 Liberty Street, is shipping large lots of concentrating tables to Mexico, Honduras and Costa Rico, which are to be operated by small motors built by the General Electric Company, the Triumph Electric Company and the Northern Electrical Manufacturing Company. The company has also some orders in hand for electric drilling equipments to be driven by General Electric motors.

1500 HP FOR MEAT PLANT.—The New York Butchers' Dressed Meat Company has just placed contracts for 1500 hp of electrical equipment to be installed in its plant at 39th Street and 11th Avenue. The engines will be built by the Fitchburg Engine Company. There will be two 600-hp tandem compound direct-connected machines and one of 300-hp capacity. The generators will be General Electric of 400-kw and 200-kw capacity respectively.

EQUIPMENT FOR TUXTLA GUTIERREZ.—The municipal lighting plant at Tuxtla Gutierrez, the capital of the state of Chiapàs, Mexico, is to be doubled. The existing equipment takes care of 1,500 incandescent and 50 arc lamps. General Rafael Pimentel, governor of the state, is now perfecting financial arrangements for the additional machinery. Mexican advices also state that he has other electrical projects in view.

HUGE CUBAN SUGAR PLANT.—The Colonial Sugar Company, of which M. R. Spelman, 33 Wall Street, is president, is about to construct the largest sugar plant in the world at Constancia, Santa Clara, Cuba, in which electricity will play an important part. The centrifugal pumps will be operated by electric power, as also the sugar cars. The capacity of the plant will be 5000 tons of cane per day.

CONSOLIDATION AT ROCHESTER, N. Y.—It is stated that negotiations are under way to merge the Rochester Gas and Electric Company, Rochester Light and Power and Rochester Railway Company. This city was the scene not long ago of a large electric lighting consolidation. Rochester is one of the pioneer trolley cities and has a large system.

HEINE AFTER MEXICAN BOILER CONTRACTS.—The Heine Safety Boiler Company is closing some fair-sized orders through the engineering and contracting firm of Van Voorhis & Sanford, of Monterey, Nuevo Leon, for boilers to be installed in Mexican power plants.

EQUIPMENT FOR FEDERAL SUGAR PLANT.—The Federal Sugar Refining Company's plant at Yonkers, N. Y., is to be equipped with considerable electrical machinery. Three 160-hp American Ball single engine, direct connected to General Electric generators of 100-kw capacity each will be installed.

LIGHTING EQUIPMENT FOR NEW JERSEY DRUG FACTORY.—The Northern Engineering Company, incorporated, White Building, has secured the contract for lighting equipment to be installed in Dodge & Olcott's new drug factory at Bayonne, N. J.

TRUMBULL SPECIALTIES FOR CUBA.—The Trumbull Electric Company, 136 Liberty Street, has secured a large contract for its various specialties from the Spanish-American Light and Power Company, Consolidated, of Hàvana, Cuba.

MANUFACTURED U. S. EXPORTS.—Exports of manufactures still promise to exceed in the fiscal year 1904 those of any preceding year. The nine months' figures of the fiscal year, just announced by the Department of Commerce and Labor, through its Bureau of Statistics, show a total of 17 million dollars greater than the corresponding months of the fiscal year 1900, in which the exports of manufactures reached their highest figures. In 1900 the exports of domestic manufactures amounted to 433 million dollars for the whole fiscal year, which was the highest figure ever recorded for the exports of domestic manufactures from the United States. In 1901 the figures showed 411 million dollars, in 1902, 403 million dollars, and in 1903, 407 million dollars. In this comparison it must not be forgotten that the 1904 figures exclude the exports of Porto Rico and Hawaii. Imports of manufactures show a decided falling off in the nine months ending with March, 1904, as compared with the corresponding period of 1903. To obtain a statement of the imports of manufactures, the Bureau of Statistics groups in three classes, viz., wholly or partially manufactured materials for use in manufacture; manufactured ready for consumption; and the group articles of voluntary use, luxuries, etc.; and this gives approximately the value of all manufactures coming into the United States, and amounts in total to $334,815,956 in the nine months ending with March, 1904, against $366,107,747 in the same months of last year, a decrease of 32 millions in imports of manufactures. It is proper to add, however, that the group "articles of voluntary use, etc.," contains some articles which could not properly be classed as manufactures, especially diamonds, of which the importation has grown steadily for several years past until the present fiscal year, which shows a decided falling off compared with 1903.

ALASKA CABLE.—A Washington despatch states that Gen. Greely, Chief Signal Officer of the army, has decided to award the contract for the manufacture of about 625 miles of submarine cable to the Safety Insulated Wire and Cable Company of New York. This cable will be used to connect Sitka, Alaska, with Fort Liscum, near Valdez, on Prince William Sound. The cable will be shipped by rail from New York to Seattle and will probably be laid the coming summer. The cable ship Burnside arrived at Nagaskai, Japan, recently, on her way to Seattle. Upon arrival there she will take on board about 800 miles of cable for laying between Sitka and Seattle. When these cable connections are completed, it will be possible to telegraph from the United States to every principal town and military post in Alaska without using Canadian lines.

STERLING ELECTRIC ORDERS.—The Sterling Electric Company, of Lafayette, Ind., has just equipped one of the large department houses at Springfield, Ohio, with a complete telephone system to work in connection with the city exchange it has recently installed there. It reports also an order for a private branch exchange from a bank in Albany, N. Y.; and an order for protectors and other apparatus from the Canton, Ill., Home Telephone Company. It has also just completed a 4-position toll board for the U. S. Telephone Company for Springfield, Ohio; the installation of a 3000-line common battery switchboard at Chillicothe, Ohio, and the installation of its 4-party line system in five of the largest cities in the West.

PLANTS FOR NEW BUILDINGS.—The Thompson-Starrett Company is about to take figures for electrical equipment to be installed in various hotel and office buildings for the construction of which they have the contracts. The Zimmerman Hotel at Richmond, Va., now being built, will have a 200-hp lighting outfit. The building will be a 10-story one. Four elevators will be put in. The new Woodruff Hotel, Brooklyn, will have a 300-kw. lighting and general power equipment. The Rockfeller skyscraper office building to be constructed in Cleveland will have a 400-kw. electrical plant. Mr. Babbit, formerly associated with the Chicago Edison Company, is the electrical engineer of the Thompson-Starrett Company.

N. Y. CENTRAL POWER PLANT.—The first actual local work towards the changing of the motive local power of the trains which run through the tunnel from the Grand Central station to Ninety-sixth Street, from steam to electricity, was made last week, when foundations plans were filed in the Bronx Bureau of Buildings for power house. This power house will be located on the south side of One Hundred and Forty-ninth Street, only 95 ft. from Long Island Sound. It will be a three-story brick structure of large dimensions; being 236.6x156.4 ft. The New York Central Railroad will erect the building, and the plans have been drawn by C. Wellesley Smith, the architect of the railroad.

TO SELL SHEPHERD ENGINES.—The firm of Mackenzie, Quarrier & Ferguson, 114 Liberty Street, New York, has effected an arrangement with the Shepherd Engineering Company, of Franklin, Pa., to act as sales agent for the Shepherd vertical automatic engine in the States of New York and New Jersey. These engines are built in sizes up to 1500 hp and in single, steeple and cross compound, single valve and four-valve types. The firm will continue to represent the selling end in this territory of the Harrisburg Pennsylvania Foundry and Machine Works for the Harrisburg horizontal engines.

EQUIPMENT FOR BROOKLYN TRAINING SCHOOL.—The Brooklyn Manual Training School is to be equipped with a considerable quantity of electric machinery. Frank Dobson, 218 East Forty-second Street, New York, is the general contractor. Manning, Maxwell & Moore secured a large order for machine tools to be electrically operated. There will be upwards of 600 hp of motors. The Buffalo Forge Company has taken an order for a marine type cross compound engine to be direct-connected to a generator. This outfit will be used to drive experimental apparatus in the laboratory.

LIGHTING EQUIPMENT FOR FERRIES.—The Hoboken Ferry Company has let the contract for the equipment to light the Erie, Jersey Central and Delaware, Lackawanna & Western ferry houses, West Twenty-third Street, New York. The machinery will have a capacity of 350 kw. There will be two 190-hp Harrisburg standard side crank engines direct-connected to 125 kw, General Electric generators and one 160-hp engine direct-connected to a 100-kw generator. The contracts were awarded through Kenneth M. Muchison, Jr., 5 W. Thirty-first Street, New York.

CHRISTCHURCH N. E. POWER HOUSE.—The New England Electric Construction Company, of Christchurch, which has secured the contract, valued at $1,250,000, for the construction and equipment of a 30-mile electric traction system in that city, is ordering more power house equipment in this market. The Alberger Condenser Company has taken the order for the surface condensers and cooling towers to take care of a 1000-kw generating outfit. The boilers will be Babcock & Wilcox. Curtis turbines two units of 500-kw each will be installed.

SHAW CRANES FOR SWEDISH IRON WORKS.—Manning, Maxwell & Moore have secured a contract for an electric traveling crane of 30 tons capacity equipped with two trolleys for installation in the open hearth plant of the Sanviken Iron Works—the largest iron and steel manufacturing concern in Sweden. The crane, which will be a duplicate of an outfit shipped the same Scandinavian works eight years ago, is to be built by the Shaw Electric Crane Company.

THE NERNST IN NEW ENGLAND.—The Nernst lamp is becoming widely introduced in New England. The company has recently received two large orders, one from the Saco & Pettee Machine Shops, Biddeford, Me., for 575 three-glower lamps, and one from the Arlington Mills, Lawrence, Mass., for 600 lamps of the 44-watt type. The second order comes in the form of a testimonial, as quite a large installation of Nernst lamps had already been made in the mills.

FANS FOR INDIA.—The Fidelity Electric Company, manufacturers of electric fans, Lancaster, Pa., is in receipt of a good-sized order for its Eclipse desk fans for India, and has just filled a large order for ceiling fans for the Orient. All southern Asia is badly in need of fan motors and the Fidelity Company is doing what it can to make life pleasant there.

LIGHTING PLANT FOR TEPIC, MEX.—The municipal authorities of Tepic, a town of 15,000 population in the State of Jalisco, Mexico, are having plans drawn up for the construction of an electric lighting system which will have American equipment. General Pablo Rocha y Portee, the governor of the territory, is primarily concerned in the project.

EQUIPMENT FOR TAMPA PLANT.—The Tampa (Fla.) Electric Company is about to increase the capacity of the plant. The company is managed by Stone & Webster, of Boston, Mass. The Hooven, Owens & Renschler Company, of Hamilton, Ohio, has secured an order for a 750-hp cross compound condensing engine for direct connection to a General Electric generator.

WELLINGTON, N. Z. SYSTEM TO BE EXTENDED.—The municipal electric traction system now being built at Wellington, New Zealand, by Macartney, McElroy & Company, Limited, Havemeyer Building, is to be extended at an additional expenditure of nearly $350,000.

MORE EQUIPMENT FOR WEST AUSTRALIA.—The Perth Electric Tramways, Limited, of 3 Lawrence Poultney Hill, London, E. C., is about to extend its power plant. The present system was built and equipped by J. G. White & Co. It is somewhat over 10 miles long.

VARIOUS EQUIPMENT FOR MEXICO.—The export house of Loiza & Co., 54 Broad Street, New York, has received a contract valued at about $50,000, which calls for the shipment of various electrical equipment to Mexico.

EQUIPMENT FOR ONTARIO POWER PLANT.—The Ontario Power Company's plant at Niagara is to have a 50-ton Shaw electric traveling crane with a span of 77 feet.

DIRECTORY OF ELECTRICAL ASSOCIATIONS, SOCIETIES, ETC.

(Published first issue of each month.)

AMERICAN ELECTROCHEMICAL SOCIETY. Secretary S. S. Stadtler, 39 S. 10th St., Philadelphia. Next meeting, St. Louis, Sept. 12-17, 1904.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION. Secretary, Dr. C. E. Skinner, New Haven, Conn. Next meeting, St. Louis, Sept. 13, 1904.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Secretary, Ralph W. Pope, 95 Liberty Street, New York. Meetings, last Friday each month.

AMERICAN RAILWAY, MECHANICAL & ELECTRICAL ASSOCIATION. Secretary, Walter Mower, 12 Woodward Avenue, Detroit. Mich.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS. Secretary, G. W. Tillson, Brooklyn, N. Y. Next meeting, St. Louis, Oct. 4, 1904.

AMERICAN STREET RAILWAY ASSOCIATION. Secretary, T. C. Pennington, 2020 State Street, Chicago. Next meeting St. Louis, Mo., Oct. 12 and 13, 1904.

ASSOCIATION OF EDISON ILLUMINATING COMPANIES. Secretary, W. S. Barstow, New York City and Portland, Ore.

CANADIAN ELECTRICAL ASSOCIATION. Secretary, C. H. Mortimer, Toronto, Ont. Next meeting, Hamilton, Ont., June 15, 16 and 17, 1904.

COLORADO ELECTRIC LIGHT, POWER & RAILWAY ASSOCIATION. Secretary, George B. Tripp, Colorado Springs, Col. Annual meeting last Wednesday in October.

CONNECTICUT STATE STREET RAILWAY ASSOCIATION. Secretary, E. W. Poole, Bridgeport, Conn. Annual meeting in November.

ENGINE BUILDERS' ASSOCIATION OF THE UNITED STATES. Secretary, D. Fleming, Harrisburg, Pa.

ELECTRICAL CONTRACTORS' ASSOCIATION OF NEW YORK STATE. Secretary, F. Fish, Rochester, N. Y. Next meeting, Utica, July 19, 1904.

ELECTRICAL TRADES SOCIETY (Member National Electrical Trades Association). Secretary, A. P. Eckert, 39 Cortlandt Street, New York. Board of Directors meets second Friday of each month.

ILLINOIS STATE ELECTRIC ASSOCIATION. Secretary, H. E. Chubbuck, LaSalle, Ill.

INDIANA PUBLIC UTILITIES ASSOCIATION. Secretary, A. M. Barron, South Bend, Ind. Next meeting, Indianapolis, Ind., Oct. 18, 1904.

INDEPENDENT TELEPHONE ASSOCIATION OF THE UNITED STATES OF AMERICA. Secretary, Frank G. Jones, 48 West Jackson Boulevard, Chicago. Next meeting, St. Louis, Sept., 1904.

INDEPENDENT TELEPHONE ASSOCIATION OF SOUTHERN INDIANA. Secretary, E. W. Pichardt, Huntingburg, Ind.

INTERNATIONAL ASSOCIATION OF MUNICIPAL ELECTRICIANS. Secretary, Frank P. Foster, Corning, N. Y. Next meeting, St. Louis, Sept. 13 and 14, 1904.

INTERNATIONAL ELECTRICAL CONGRESS. General secretary, Dr. A. E. Kennelly, Cambridge, Mass. Meeting, St. Louis, Sept. 12-17, 1904.

INTERSTATE INDEPENDENT TELEPHONE ASSOCIATION. Secretary, E. M. Coleman, Louisville, Ky.

IOWA ELECTRICAL ASSOCIATION. Secretary, W. S. Porter, Eldora, Ia. Next meeting, Dubuque, Ia., April, 1905.

IOWA TELEPHONE ASSOCIATION. Secretary, C. C. Deering, Des Moines, Ia. Next meeting, second Tuesday, March, 1905.

KENTUCKY INDEPENDENT TELEPHONE ASSOCIATION. Secretary, James Maret, Mount Vernon, Ind.

MAINE STREET RAILWAY ASSOCIATION. Secretary, E. A. Newman, 471 Congress Street, Portland, Me.

MASSACHUSETTS STREET RAILWAY ASSOCIATION. Secretary, Charles S. Clark, 70 Kilby Street, Boston, Mass. Meets second Wednesday of each month, except July and August.

NATIONAL ARM, PIN & BRACKET ASSOCIATION. Secretary, J. B. Magers, Madison, Ind. Next meeting, St. Louis, July, 1904.

NATIONAL ELECTRICAL CONTRACTORS' ASSOCIATION OF THE UNITED STATES. Secretary, W. H. Morton, 44 Whitesboro Street, Utica, N. Y. Next meeting, St. Louis, Mo., September 14, 15 and 16, 1904.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Secretary, Ernest H. Davis, Williamsport, Pa. Next meeting, Boston, Mass., May 24, 25 and 26, 1904. Headquarters, Hotel Vendome.

NEW ENGLAND STREET RAILWAY CLUB. Secretary, J. H. Neal, 101 Milk Street, Boston, Mass. Meets last Thursday of each month.

NEW YORK ELECTRICAL SOCIETY. Secretary, G. H. Guy, 114 Liberty Street, New York.

NORTHWESTERN ELECTRICAL ASSOCIATION. Secretary, T. R. Mercein, 85 Michigan Street, Milwaukee, Wis. Next meeting, St. Louis, Sept., 1904.

OHIO STREET RAILWAY ASSOCIATION. Secretary, Chas. Currie, Akron, Ohio.

OHIO ELECTRIC LIGHT ASSOCIATION. Secretary, D. L. Gaskill, Greenville, Ohio. Next meeting, Sandusky, Ohio, Aug. 16, 17 and 18, 1904.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS. Secretary, C. J. Miller, Canton, Ohio. Next meeting, Columbus, O., May 13, 1904.

PACIFIC COAST ELECTRIC TRANSMISSION ASSOCIATION. Secretary, G. P. Low, 600 Rialto Building, San Francisco, Cal. Next annual meeting June 21, 1904.

SOUTHWESTERN ELECTRICAL ASSOCIATION. Secretary, J. L. Ellis, Oklahoma City, Okla.

SOUTHWESTERN GAS, ELECTRIC & STREET RAILWAY ASSOCIATION. Secretary, Frank E. Scovill, Austin, Texas.

STREET RAILWAY ACCOUNTANTS' ASSOCIATION OF AMERICA. Secretary, W. B. Brockway, 40 Morris Street, Yonkers, N. Y.

STREET RAILWAY ASSOCIATION OF THE STATE OF NEW YORK. Secretary, W. W. Cole, Elmira, N. Y. Next meeting, Utica, N. Y., Oct. 11 and 12, 1904.

VERMONT ELECTRICAL ASSOCIATION. Secretary, C. C. Wells, Middlebury, Vt. Next meeting, Montpelier, Sept. 21 and 22, 1904.

WESTERN SOCIETY OF ENGINEERS, Electrical Section. Secretary, J. H. Warder, 1737 Monadnock Block, Chicago, Ill.

General News.

THE TELEPHONE.

SITKA, ALASKA.—The Long Distance Telephone Company will build a line to Unalakleet from Chinik, the present terminus of the line.

MARVELL, ARK.—The Marvell Telephone Company has been incorporated with a capital stock of $20,000. The directors are E. E. McMurray and others.

LITTLE ROCK, ARK.—The New Long Distance Telephone Company has been incorporated with a capital stock of $200,000. J. B. Kin is president and general manager.

LOS ANGELES, CAL.—An ordinance is being prepared requiring the reconstruction of conduit each year by the telephone and lighting companies.

CAMPUS, CAL.—The Campus Telephone Company has been incorporated with a capital stock of $2,500, by J. D. Brophy, M. R. Walsh, N. L. Mamer and others.

TWO ROCK, CAL.—The residents of Two Rock have organized the Two Rock Valley Telephone Company. George Gaston is secretary of the company. The line will be 25 miles long.

SANTA ROSA, CAL.—Sealed bids will be received by F. L. Wright, county clerk, until May 7, for a franchise to construct and maintain a telephone system in Sonoma County, as applied for by J. M. Laughlin. Bids will also be received at the same time and place for similar privileges applied for by C. L. Patterson.

WATERBURY, CONN.—The Waterbury Automatic Telephone Company has increased its capital stock from $10,000 to $50,000.

WASHINGTON, D. C.—The Terra Telephone Company has been incorporated with a capital stock of $100,000. The directors are E. Schooley, F. C. Geiger and others.

WASHINGTON, D. C.—Sealed proposals will be received at the office of the District Commissioners until noon, May 7, for furnishing underground signal and telephone cables for the electrical department of the District of Columbia.

BARTOW, FLA.—Mr. J. M. Oliver, of Orlando, is making arrangements to build a telephone line from Jacksonville to Tampa by way of Bartow. The enterprise is to be known as the Florida Co-operative Telegraph & Telephone Company and will be incorporated at $100,000. Building operations of this system will begin about May 15.

JACKSONVILLE, FLA.—The Southern Bell Telephone & Telegraph Company is stringing a direct copper-wire line between Jacksonville and Fernandina. There will be four wires on the new line.

PEORIA, ILL.—The Interstate Telephone Company will install a service here.

HARDIN, ILL.—The Calhoun Telephone Company has increased its capital from $15,000 to $25,000.

EDWARDSVILLE, ILL.—The Oak Grove Telephone Company has been organized in Fort Russell Township.

MATTOON, ILL.—The Gayes Mutual Telephone Company of Mattoon has increased its capital stock from $2,400 to $4,980.

CHICAGO, ILL.—The Chicago Telephone Company has secured a 20-year blanket franchise, covering all the towns in Lake County. The grant is not exclusive.

DANVILLE, ILL.—A contract for the new building of the Vermillion County Telephone Company has been awarded at $16,000. Mr. H. B. Walter will erect the building.

ATHENS, ILL.—The Menard County Telephone Company has been organized and has received a franchise. Toll lines will be built to connect with the Interstate Independent Telephone & Telegraph Company at Springfield and other points.

CHICAGO, ILL.—The directors of the Automatic Electric Company have declared the regular quarterly dividend of two per cent., payable May 2. The company is reported in a prosperous condition. It was stated that 26 cities are now using the automatic telephone system and when present contracts are filled the system will be used in 59 cities. It was stated that by May 15 the Illinois Tunnel Company will have about 8300 instruments in operation in the downtown district of Chicago.

JASPER, IND.—The Velpen, Ireland and Atwell Telephone Company has sold its plant to the Dubois County Telephone Company at Huntingburg.

INDIANAPOLIS, IND.—The American Telephone & Telegraph Company is getting the right of way for a trunk line to extend from Chicago to this city.

ST. JOSEPH, IND.—The German Township Home Telephone Company, recently organized with 65 members, is constructing an exchange at this place.

PROVIDENCE, IND.—The Providence Telephone Company is running its line to Banta and Trafalgar. The company contemplates putting in a new switchboard this summer.

HEBRON, IND.—A telephone line between this place and Macksburg has been completed and as soon as the exchange is installed, service will be given a large number of patrons.

COLFAX, IND.—The American Telephone & Telegraph Company proposes to build a trunk line from Chicago to Indianapolis and the work of securing the right of way is now proceeding.

LAWRENCE, IND.—The Lawrence Telephone Company has incorporated with a capital stock of $10,000. The directors are M. M. Hindman, L. H. Rattliff and Harry Mollenkopf.

CLEVELAND, IND.—The Cleveland Telephone Company, of Hancock County, has been incorporated with a capital stock of $160, by E. H. Thomas, Ada L. Sample, E. L. Furry and others.

CHESTERTON, IND.—The town council has granted a franchise to the

Portage Home Telephone Company. The rates are limited to $1 and $1.25 per month for residence and business telephones.

ELKHART, IND.—The Home Telephone Company, of this city, is laying 14,000 feet of new additional cable. This was necessary to the installing of the many new telephones which have been applied for.

GREEN CASTLE, IND.—A new telephone company has been organized in Madison township. The officers are Charles Kyte, president; Zimri Boswell, vice-president; J. N. Dalby, treasurer, and Thomas Heady, secretary.

FLORA, IND.—A combination of the independent telephone companies of Flora, Delphi, Frankfort, Logansport and Kokomo has been effected for mutual protection against the invasion of co-operative systems in this section.

LAFAYETTE, IND.—The Lafayette Telephone Company suffered an annoying accident on April 16. An electric light wire came in contact with one of the telephone leads and about 1200 instruments were disabled and a number damaged.

LAWRENCE, IND.—The Lawrence Telephone Company has increased its capital stock $10,000 for the purpose of extending its lines, installing a new switchboard and making other betterments. M. M. Hindman is president and L. H. Ratliff, secretary.

BATTLE GROUND, IND.—The Cairo Telephone Company, of this town, has sold its plant and property to Eldon T. Roadrick, of Brookston, one of the original stockholders. Mr. Roadrick announces that he will extend the lines and improve the plant.

ROYAL CENTER, IND.—G. S. Akers, of Ambia, Ind., has purchased the Thomas-McCombs telephone plant in this city. Mr. Akers announces that he will at once put in a new and improved switchboard. He will also make extensions and other improvements.

BICKNELL, IND.—The Bicknell Telephone Company has increased its capital stock in the sum of $12,000. The object is to extend its lines, improve the plant and increase the capacity of the switchboard. Joseph Bare is president and John S. Hoover, secretary.

INDIANAPOLIS, IND.—The Northwestern Long Distance Telephone Company, of Mohawk, Hancock County, has incorporated with a capital stock of $2,000. J. W. Murphy, Sr., Emory Pratt, G. W. Allen, J. M. Duneau and Clint Parker are the incorporators.

EVANSVILLE, IND.—It has been stated by the directors and a few stockholders of the Evansville Municipal Telephone Company that an attempt will be made to form a local independent company entirely eliminating the municipal feature and putting it on the basis of other independent companies

NEW CASTLE, IND.—The Cadiz Telephone Company, the original and largest co-operative telephone company in this county, will in the future have no affiliation with the Bell interests. At a recent meeting of the stockholders, a resolution was passed, declaring that all business in the future will be done with independent companies.

SOUTH BEND, IND.—The annual meeting of the South Bend Home Telephone Company was held recently and Theodore Thorward was elected president, M. B. Slatey, treasurer, and Elmer Stoll, secretary. C. H. Worden heads the board of directors. The company is in a flourishing condition and declared a regular semi-annual dividend of two per cent.

CORYDON, IND.—The Eureka Telephone Company will make a number of extensions of its lines at once. The company has issued a new directory which shows that it has three exchanges in the county with telephones as follows: Corydon, 170; Laconia, 166; Mauckport, 85. The following are the officers: Ed. F. Windell, president; Chas. Yeager, vice-president; H. P. Beanblossom, secretary; L. S. Flesbman, treasurer.

ELWOOD, IND.—Sixty-five more farmers on the rural lines were connected by telephone with Elwood recently. One hundred and thirty applications are also waiting to be approved by the telephone company. The Delaware and Madison Counties Telephone Company, the independent line, is working along the rural lines and five new circuits have been built to meet the demand. Over 300 farms are already connected with the local exchanges.

NAPOLEON, IND.—The citizens of Delaware and Laughery townships, Ripley County, have organized a stock company to build a telephone system from Napoleon, Laughlin township, to connect with Dr. Gibson's line which runs into Batesville. The officers are: President, John Bullman; secretary-treasurer, Granville Thackery. Work on this line will begin as soon as the officials can purchase the material and contract for its construction.

INDIANAPOLIS, IND.—The leases on the property and equipment of the New Telephone Company have been signed over to the Indianapolis Telephone Company, which was organized recently to take the property of the New company and extend and improve the service. The Indianapolis Telephone Company has also taken a mortgage from the New company for $150,000, which covers the floating indebtedness, and all future work of extending the lines, laying new cables and installing branch exchanges will be done by the Indianapolis company.

BOISE, IDA.—The Rocky Mountain Bell Telephone Company has definitely announced its decision to extend its lines as far as the famous Thunder Mountain district as soon as the state road to that point, 75 miles in length, is completed.

SCHLESWIG, IA.—The Schleswig Telephone Company has bought material for 20 miles of extensions.

WEST UNION, IA.—The Rogers Telephone Company has been formed with a capital stock of $25,000.

ELDON, IA.—Mr. C. A. Mann, of Sioux City, has bought the Eldon Telephone Company and will improve and extend the service.

CONESVILLE, IA.—The Conesville Telephone Company has been incorporated with a capital stock of $10,000. J. G. Van Lent is president.

CEDAR FALLS, IA.—A stock company has been formed to install an independent telephone system here. N. H. Harris is president and F. O. Jackson, secretary.

OLATHE, KAN.—The De Soto & Olathe Telephone Company has filed articles of incorporation, the capital being $2,000.

JUNCTION CITY, KAN.—The Union Telephone & Telegraph Company's new toll line to Topeka is now in operation. It furnishes the independent companies of central Kansas connection with Kansas City and other eastern points, and its construction cost the company $125,000.

FLEMING, KY.—The Ewing Mayslick Telephone Company, of Fleming, has been incorporated.

NEW ORLEANS, LA.—An effort is being made to have all telephone and telegraph wires placed underground on Canal Street, between Liberty and City Park Avenue.

LAUREL, LA.—The Cumberland Telephone Company has acquired possession of the Mississippi Telephone Company, of this place. Both the Laurel and Ellisville exchanges are included in the deal and half of the line between here and Hattiesburg.

ROCKLAND, ME.—The Northwestern Telephone Company is securing permission to enter Lewiston and Auburn.

SKOWHEGAN, ME.—The New England Telegraph & Telephone Company has decided to install a system here.

NEW BEDFORD, MASS.—The Automatic Telephone Company, it is stated, contemplates increasing its capital stock to extend its business to adjacent towns.

KALAMAZOO, MICH.—The Citizens' Telephone Company will spend $80,000 in improvements in this city.

LANSING, MICH.—The Citizens Telephone Company will make several extensions and improvements to its system during the coming summer. All the new work will be made with a view to the early installation of the automatic system.

TORDENSKJOLD, MINN.—The Independent Mutual Telephone Company will extend its line 35 miles.

ARLINGTON, MINN.—The Merchants' Telephone Company has been incorporated with a capital stock of $4,000.

OSSEO, MINN.—The Rural Telephone Company has been organized to build a line in Hennepin and Wright counties. The capital stock is $50,000.

JACKSON, MISS.—The Cumberland Telephone Company is changing its local exchange to the central energy system and will reconstruct a large amount of pole line.

OTTERVILLE, MO.—The Otterville-Smithton Telephone Company has increased its capital from $2000 to $5000.

DE KALB, MO.—The DeKalb Telephone Company has been incorporated with a capital stock of $10,000. The directors are W. W. Head, C. V. Davis and others.

DEWITT, NEB.—The Dewitt Telephone Company has increased its capital stock to $20,000, and will make extensive improvements in its exchange.

OMAHA, NEB.—The Farmers' Telephone Company, of Alexandria, Thayer County, has been incorporated with a capital stock of $5,000.

OMAHA, NEB.—The new central energy automatic switchboard of the Nebraska Telephone Company was recently cut into srvicve. It cost $250,000.

ENDICOTT, NEB.—The Endicott Telephone Company has filed articles of incorporation, the capital stock being $2,500. The incorporators are H. Stolz, H. E. Potter, J. A. Blausett.

SWEDESBORO, N. J.—The People's Rural Telephone Company contemplates extending its lines to reach several towns in this vicinity. Forty miles of line will be erected and 120 telephones have been subscribed for.

HOPEWELL, N. J.—The Hopewell Telephone & Construction Company has agreed to sell its local system to the Delaware & Atlantic Telephone & Telegraph Company. The system will be transferred about May 15 when the Bell interests will come in possession.

TROY, N. Y.—The Commercial Union Telegraph Company of this city has increased its capital stock from $10,000 to $800,000.

AMSTERDAM, N. Y.—The Amsterdam Automatic Telephone Company has increased its capital stock from $15,000 to $100,000.

POUGHKEEPSIE, N. Y.—The Dutchess County Telephone Company will make some important extensions to its service. Exchanges will be installed in several places.

BABYLON, L. I., N. Y.—The village board has granted permission to the New York & Long Island Telephone Company to come into Babylon by an underground circuit.

KILLAWOG, N. Y.—The Rural Telephone Company has been organized here by business men and farmers. The directors are T. R. Hitt, president; C. J. Tarble, vice-president; W. C. Ensign, secretary, and P. Hilsinger, treasurer.

SYRACUSE, N. Y.—The Central New York Telephone & Telegraph Company has let the contract for the construction of a subway under the Oswego Canal, in North Salina Street, this city. Seven 3-inch iron ducts will be laid.

RED CREEK, N. Y.—At a conference held here it was arranged to unite as one concern the Wayne-Monroe Telephone Company and the Ontario Telephone Company of Oswego. The Wayne-Monroe Company connects with the Inter-ocean Telephone Company, and by this service is enabled to reach Rochester, Buffalo, Ohio, Southern New York and Pennsylvania. In the Western New York system there are said to be 50,000 telephones.

REIDSVILLE, N. C.—The Reidsville telephone exchange has recently been remodeled and the system is now in fine working order with 150 telephone connections on the switchboard.

CHARLOTTE, N. C.—The Automatic Electric Company, of Chicago, has installed an experimental set of telephone instruments at Greensboro, N. C., which will be adopted in the proposed independent system, unless the present differences with the Bell Company are adjusted.

GREEN SPRING, OHIO.—The Green Spring Telephone & Electric Company has increased its capital stock from $20,000 to $35,000.

GREENWICH, OHIO.—The Fitchville Telephone Company is preparing to build a line into Greenwich to connect with the exchange at that place.

TOLEDO, OHIO.—The Central Telephone Company has been incorporated with a capital stock of $100,000. The directors are J. S. Brailey, H. A. Barber and others.

NORWOOD, OHIO.—The independent telephone interests that recently failed to secure a franchise in the village of Norwood are making an effort to secure the passage of their ordinance in an amended form.

JEWETT, OHIO.—Fred Patton, of this place, is building a number of farmers' lines throughout this district. He is preparing to build a new line from Jewett to Hanover and Stillwater. The lines will be connected with the exchange at Jewett.

NEWARK, OHIO.—The Central Ohio Telephone Company, of Centerburg, Knox County, has been incorporated by Charles L. Bishop, T. P. Sylvan, E. E. McGuire, J. E. Litzenburg and G. N. Jackson. Capital stock, $10,000. It will build an exchange at Centerburg with lines in Morrow, Licking and Delaware counties.

GUTHRIE, OKLA.—The Chickasaw & Choctaw Telephone Company, of Durant, has purchased the Hugo Telephone Exchange and the toll line, 25 miles in length.

TORONTO, ONT.—In discussing the fire situation at a special session of the Board of Control, action was taken with a view to placing all wires underground within the city.

DURKEE, ORE.—The Express Telephone & Telegraph Company has been incorporated by W. G. Ayre, F. S. Hub and F. L. Moore, to build a system in the Brunt River region.

WILLAMETTE, ORE.—The Willamette & Wilsonville Telephone Company has been organized and will incorporate to construct a line between Stafford and Oregon City. Mr. Charles Baker is president; G. H. Rogers, treasurer; F. C. Geery, general manager.

PHOENIXVILLE, PA.—The citizens of this place propose to organize a local mutual telephone company. Mr. William Ellis is one of the promoters.

EASTON, PA.—Mr. A. G. Dickson, of Philadelphia, special master, April 16, sold the system of the New Jersey & Pennslyvania Telephone Company to J. Davis Broadhead, of South Bethlehem, attorney for the bond holders, for $25,000.

SAN ANTONIO, TEX.—The Eureka Telephone Company is rebuilding its telephone line between this city and Fredericksburg. Its line between San Antonio and Alice has just been rebuilt.

AUSTIN, TEX.—The Texas Telegraph & Telephone Company, which owns and operates more than 600 miles of telephone lines in this part of the State will rebuild its lines between Burnst and Lampasas, a distance of about 25 miles. It will also make extensions of some of its other lines. At a recent meeting of the board of directors of the company held here, Col. C. C. Gibbs, of San Antonio, Tex., was re-elected president. He can give information in regard to contemplated improvements.

SALT LAKE CITY, UTAH.—The competitive war between the Rocky Mountain Bell Telephone Company and the Utah Independent Telephone Company commenced a few days ago when the management of the new company, which is now ready to begin business here and in Ogden, stating that it would utilize the same numbers now in use by the Bell Company. The manager of the Bell Company has protested, stating that the numbers are copyrighted and cannot therefore be lawfully used by the rival company.

RICHMOND, VA.—The Rural Retreat Mutual Telephone Company has been incorporated with a capital stock of $5000. Mr. John Killinger is president.

RICHMOND, VA.—The Patrick County Telephone Company, of Stuart, has been incorporated with a capital stock of $1,000 to $5,000. Mr. T. L. Clark is president.

KALAMA, WASH.—The Kalama Electric Light & Power Company will soon commence the installation of a telephone system.

PORT TOWNSEND, WASH.—The Citizens' Independent Telephone Company, of this place, has been incorporated with a capital stock of $10,000. The trustees are A. T. West, N. C. Strong, G. M. Parmlee, D. S. Troy and M. E. Harris.

BELLINGHAM, WASH.—The International Telephone Company is being organized here to build a connecting line between Bellingham and Victoria, B. C., through the San Juan Archipelago, a distance of 70 miles. The circuit will include 17 miles of cable costing $60,000.

ST. CROIX, WIS.—The St. Croix Mutual Telephone Company has been formed here.

MILWAUKEE, WIS.—The Milton & Milton Junction Telephone Company has increased its capital stock from $5,000 to $20,000.

ALMA, WIS.—The Tenney Telephone Company has been organized, Dr. J. S. Tenney being president and J. Accola, secretary.

MILWAUKEE, WIS.—The Great Western Telephone & Telegraph Company has decided to dissolve. Mr. Charles Webster is president and Robert C. Brown, secretary.

WILLOW SPRINGS, WIS.—The Willow Springs Farmers' Telephone Company has been incorporated with a capital stock of $4,000. The directors are Frank McCarville and others.

ELMWOOD, WIS.—The Highland Telephone Company, of Elmwood, has been organized to operate a system in Pierce and Dunn counties. The capital stock is $1000, and the incorporators are H. A. Miles, W. H. Young, Hugh Bell, Ira J. Smith and William Fensenmaier.

ELECTRIC LIGHT AND POWER.

MORENCI, ARIZ.—It is reported on apparently trustworthy authority that the Arizona Copper Company is interested in a project to establish a large electric power plant on the Blue River for the purpose of furnishing lights and power for this mining camp and town.

MALVERN, ARK.—Mr. C. W. Turner, proprietor of the electric light plant in this place, proposes to install a new dynamo and boiler.

SANTA PAULA, CAL.—The Santa Paula Electric Company proposes to extend its lines for the general distribution of light and power.

ALTURAS, CAL.—The Alturas Electric Light & Power Company has been incorporated with a capital of $20,000, by D. E. Mulkey and I. W. Gibbons.

OAKLAND, CAL.—The Oakland Electric Company will develop a second water-power station having a capacity of 15,000-hp, and will also install 750-hp steam plant during the next year. The probable cost of these improvements will be about $100,000.

MARTINEZ, CAL.—The Contra Costa Electric Light Company proposes to extend its lines to Concord, a distance of seven miles. The company purchases its current from the California Central Gas & Electric Corporation of San Francisco and has the city contract for street lighting, besides doing commercial lighting.

SAN FRANCISCO, CAL.—After a delay of many months the Mutual Electric Light Company of San Francisco, has given orders to at once construct the new electric power station at the intersection of Spear and Folsom Streets, covering a lot 137½ feet square. The machinery for the initial installation of 5,000-hp is on hand with the exception of the boilers. Additional boilers will be ordered, although the company has six Heine boilers at its present plant at Howard and New Montgomery Streets. This station will be abandoned. The equipment of the new plant will include two generating units each consisting of a 2,500-hp Pennsylvania Iron Works horizontal compound engine, direct connected to a Bullock 1,500-kw 2-phase generator. Current will be supplied at 2,200 volts. Additional boilers can be placed on the upper floors of the station, and by utilizing all of the ground available the capacity of the plant can be increased to 40,000-hp. Oil fuel will be used. A bond issue of $400,000 is to be authorized at a shareholders' meeting June 21. E. H. Rollins & Sons, of San Francisco and Boston, have agreed to purchase the bonds to the amount of $250,000.

GRAND JUNCTION, COL.—The Grand Junction Electric & Gas Company has doubled the capacity of its plant during the last three months. Mr. Charles S. Newton is manager.

GLENWOOD SPRINGS, COL.—The Colorado Power Irrigation Company, Denver, has purchased a water right about 12 miles above Glenwood Springs on the Grand River.

WATERBURY, CONN.—Bids will be received by Jas. Knox Taylor, supervising architect, Treasury Department, Washington, D. C., on May 26 for the installation of a conduit and electric wiring system for the U. S. post office at Waterbury.

BLAKELY, GA.—The water and electric light plant owned and operated by the city was destroyed by fire April 15.

THOMASVILLE, GA.—The town authorities have under consideration the construction of water works and an electric light plant.

BLUE RIDGE, GA.—The Blue Ridge Electric Light & Power Company contemplates making some extensive improvements to its system in the near future. It is proposed to utilize water power for the generation of current for electric light and power. Mr. E. B. Garwood, of Blue Ridge, is manager of the company.

LEWISTON, IDA.—Francis Jenkins, of Moscow, has purchased from John O. Bender, of Lewiston, the water right at Elk Creek Falls, about 50 miles from here. Mr. Jenkins will organize a company to develop an electric power there for running electric railways and light plants, grist and sawmills, and manufacturing plants of various kinds. A survey of the falls shows that 3,000-hp can be generated.

MOUND CITY, ILL.—Chas. Cureen is about to petition the City Council for a franchise to install and operate an electric plant here.

CHICAGO, ILL.—Mayor Harrison, in his annual message to the Council, urges the passage by the next Legislature of a law to enable the city to own gas and electric light plants.

CARTHAGE, ILL.—The Carthage Electric Light & Heating Company has changed its name to Carthage Electric Light & Power Company, and increased its capital stock from $20,000 to $50,000.

ELGIN, ILL.—The Fox River Light, Heat & Power Company has absorbed by purchase the Aurora, Elgin and Chicago Light & Power Company to avert a rate war.

FREEPORT, ILL.—The Pecatonica River Power Company has been incorporated with a capital of $5000, to operate electric lighting, railway and power plants. Incorporators: Henry B. Witte, Jos. H. Vincent and Chas. B. Courtney.

NEW HAVEN, IND.—Bids are wanted May 24 for constructing an electric light plant. John M. Jackson is Town Clerk.

GRETNA, IND.—The Jefferson Ice & Electric Light Company will enlarge the capacity of its plant in order to light the towns of Gretna and McDonoughville, if the contract can be secured in these towns.

SOUTH BEND, IND.—The South Bend Electric Company, F. A. Bryan, manager, is erecting a sub-station in South Bend from which power will be distributed from the Twin Branch Dam of the St. Joseph & Elkhart Power Company and the Buchanan dam of Mr. C. A. Chapin.

KOKOMO, IND.—The Kokomo, Marion & Western Traction Company is building a new power plant with a capacity of 800-kw., all direct connected units. The new plant will cost $150,000 and will be ready for operation July 1 next.

MARION, IND.—A bitter political fight is being waged in this city, the issue being a franchise for an electric light and heating company. The council is being charged with an intention of conspiring to sell the municipal electric light plant to the Marion Light & Heating Company which has a monopoly in commercial lighting and heating. An injunction suit has been filed to prevent the city officials from disposing of the municipal plant.

NOBLESVILLE, IND.—All bids for the contract to light this city for ten years were rejected because they were filed twenty minutes after 7 o'clock, April 19, the time advertised. It is thought that the council took advantage of this slight omission in order to enable the Noblesville Hydraulic Company, which is building a dam across White River for the purpose of furnishing electricity to Noblesville, to submit a bid. The company could not bid at present, owing to some cases pending in the Supreme Court, but will be ready to submit a bid any time after June 15. Bids will be re-advertised.

SPRINGFIELD, KY.—The Springfield Water & Electric Light Company is making large extensions to its system.

PADUCAH, KY.—The Board of Public Works has decided to improve the electric light plant.

NEW ORLEANS, LA.—Notwithstanding the acceptance of the lighting bid of the New Orleans Railroad & Power Company for furnishing electric power for illuminating in this city, it is positively stated by President Dreyfous, of the Consumers Electric Company that the building of its plant will begin at an early date.

NEW ORLEANS, LA.—Comptroller Tujague, on April 18, sold the municipal lighting franchise at public auction to the New Orleans & Carrollton R. R., Light & Power Company, the lowest bidder. The figures were $69 per lamp for the overhead lamps; $85 per lamp for the lamp fed by the underground system, and 6 cts. per kw-hour for the incandescents and other lights used in the public buildings.

LAKE CHARLES, LA.—The Lake Charles Ice, Light & Water Works Company contemplates the addition of a 300-kw generator, a 100-light station transformer and 50 alternating current series arc lamps. Mr. J. A. Landry is president and manager of the company.

SPRINGFIELD, MASS.—The United Electric Light Company will install a 100-kw steam turbine about the 1st of October next.

BALTIMORE, MD.—Bids will be received by the Board of Awards until May 11 for installing and maintaining electric lights in Druid Hill Park. W. W. Crosby is general superintendent of the Park Commissioners.

BALTIMORE, MD.—The Maryland Telephone & Telegraph Company has had introduced in the council a new ordinance for electric lighting privileges. The original bill was vetoed by the mayor. It is claimed that the Maryland Company has in the new ordinance met the objections of the mayor.

GERARD, ILL.—The Gerard Electric Light Company is in need of a larger alternating current generator. Mr. H. L. Wares is superintendent and chief engineer. The plant is operated by the municipality.

WATERVILLE, ME.—The Ft. Halifax Power Company has been organized at Waterville to construct an electric light and power plant in Benton and Winslow; capital, $250,000. Harvey P. Eaton, of Waterville, president and treasurer.

PAW PAW, MICH.—The village electric light plant will be entirely renewed in the near future.

ZEELAND, MICH.—The Zeeland Water & Light Company will probably install a 15-kw direct-current, 250-volt marine set before next winter, for use after midnight.

BREWSTER, MINN.—The Village Board has under consideration the construction of an electric plant.

CANNON FALLS, MINN.—Bids are wanted May 14 for installing a power plant on the Cannon River near this village. Approximately 10,000 cubic yards of concrete, three horizontal, direct connected water wheels, operating under 46 ft. head and generating 1575-kw at 30,000 volts, with three generators, step-up transformers, switchboards, oil switches, etc. Address G. S. Edmonstone, chief engineer, 518 Globe Bldg., St. Paul.

STARKVILLE, MISS.—The municipal electric light plant is being enlarged to about twice its former capacity.

SEDALIA, MO.—The Sedalia Water & Light Company will build an entirely new plant during the coming summer.

SANFORD, N. C.—The Sanford Electric & Power Company will extend its lines to Jonesboro, N. C., a distance of two miles and add 500 lights to the service.

CONCORD, N. C.—The municipal electric light plant will be changed over to alternating current during the next 12 months, and new equipment will be installed, including 60 arc lights and 1500 incandescents, with suitable machinery for the service.

COOPER, NEB.—The electric light plant at this place was destroyed by fire April 18. Mr. W. T. Martin, the proprietor of the plant, will rebuild at once. In the meantime the town is in darkness.

PRINCETON, N. J.—Richard Stockton has been appointed receiver for the Princeton Light & Power Company. It is stated that the assets of the company are $400,000 and the liabilities about $600,000.

ASBURY PARK, N. J.—The Atlantic Coast Electric Company is building another new circuit to Spring Lake, a distance of six miles. The circuit will be operated only by day during the months of May, June, July, August and September.

JERSEY CITY, N. J.—The Street and Water Board has granted permission to the United Electric Company, of New Jersey, which is now included in the Public Service Corporation, to construct subways for electric light, heat and power wires in certain streets of this city.

CHATEAUGAY, N. Y.—The Chasm Power Company proposes to build a line to Burke, N. Y., a distance of five miles, for the extension of its light and power service.

NIAGARA FALLS, N. Y.—It is stated that the Ontario Power Company contractors on the Canadian side of the river are experiencing considerable difficulty with land slides. Hardly a day passes that there are not one or more slides of land in the wheel pits and in the long trench of the Company. The trench now contains a large quantity of earth thus deposited, which will be removed as soon as the weather permits.

WILMINGTON, OHIO.—The Wilmington Water & Light Company is building an entirely new plant, to be completed by September next.

TOLEDO, OHIO.—Mayor Jones in his annual message advises Council to empower the Board of Public Service to advertise for bids for installing a 2000-arc light lighting system to be paid for by the city without a bond issue.

BELLAIRE, OHIO.—The Belmont Electric Light & Power Company is planning additions and improvements to the power plant that will almost double its capacity.

COLUMBUS, OHIO.—Bids will be received May 31 by the Board of Trustees of Ohio State School for the Blind for furnishing and installing one 200-hp water-tube boiler; two 100-hp tubular boilers or four 100-hp tubular boilers. H. P. Crouse is president.

MEAFORD, ONT.—Messrs. W. Moore & Sons, proprietors of the electric light plant, are developing a water power with a capacity of about 400 horsepower.

KLAMATH FALLS, ORE.—The Klamath Falls Light & Water Company will install a gasoline engine to take care of the increasing demand for its service.

SUMPTER, ORE.—The Sumpter Light Water Company will, about July 1 this year, change its power from steam to water.

CORRY, PA.—A new power house for the Corry City electric light plant is contemplated.

MECHANICSBURG, PA.—The United Electric Company is rebuilding and reconstructing its plant and installing new equipment.

EASTON, PA.—The directors of the People's Electric Light & Power Company have re-elected Dr. Evans as president; Mr. Osterstock, treasurer, and Mr. Ormsby, secretary.

CHRISTIANA, PA.—Mr. A. J. Melchen, owner of the electric light plant here, proposes to extend his system in order to take in three towns and farmer districts.

LANSDALE, PA.—The equipment of the municipal electric light plant in this place will be extended during the present year by the addition of one 120-kw alternating current machine, one 250-hp Corliss engine and one boiler.

IROQUOIS, S. D.—The electric light plant of this village is operated by the municipality. The power is furnished by a "Little Giant" turbine. The management contemplates putting in a second dynamo in order to avail of all the power of the water wheel. The chief engineer of the plant is Keefus Bartain. Mr. Charles E. Cameron is chairman of the commissioners.

ENID, IND. TER.—The Chickasha Electric & Gas Company has been incorporated with $45,000 capital. The incorporators are J. M. Dodson, H. H. Watkins and J. B. Thieme.

CALDWELL, TEX.—An electric light and power plant is to be established here. The Business Men's League can give information in regard to the project.

SAN ANTONIO, TEX.—Bids are wanted May 10 for installing a system of electric light wiring and fixtures in U. S. Court House and Post Office here. Address H. A. Taylor, Assistant Secretary Treasury Department, Washington, D. C.

BLACKSBURG, VA.—The Virginia Polytechnic Institute will increase the capacity of its electric plant to about three times the present size.

MARTINSVILLE, VA.—The town of Martinsville contemplates installing an electric light and power plant with a capacity of 1000-hp, to be operated by the town. Besides the lighting system, power will be sold for industrial purposes. The water power of Smith River, at a point one mile south of town, will be utilized. Engineers are now on the ground making surveys and estimates. Mr. A. L. Scott, representing Lockwood & Green, of Boston, Mass., is the engineer in charge.

MONROE, WASH.—The Monroe Water & Light Company recently organized will install a water system and an electric light plant.

FT. WRIGHT, WASH.—Bids are wanted May 31 for lighting the post with electricity; separate bids are wanted for the apparatus. Address Capt. W. C. Wren, Constructing Q. M., Vancouver Barracks.

MILTON, WASH.—Engineers for the Oregon & Washington Power Company are at work on a site for the power plant on the South Fork of the Walla Walla River near this place. It is expected to have the plant in operation by October 1 and to furnish light and power throughout the section of country between Walla Walla, Wash., and Pendleton, Ore. The company bought up the Walla Walla Electric Light Co. and the Pendleton Electric Light & Power Company, and is financed by Philadelphia capital.

IRON RIVER, WIS.—The Iron River Water, Light & Power Company will install a water power in the near future.

WITTENBERG, WIS.—Bids will be received May 9 by John England, village clerk, for constructing an electric light plant.

OSHKOSH, WIS.—The property of the Oshkosh Electric Light & Power Company is to be taken out of the hands of a receiver in the near future and sold on foreclosure. It is stated that the plant is now on a paying basis and the services of a receiver can be dispensed with.

THE ELECTRIC RAILWAY.

HOT SPRINGS, ARK.—The Hot Springs Street Railway will be extended and a number of improvements made to the property. President S. W. Fordyce, Chemical Building, St. Louis, has the matter in charge.

NANAIMO, B. C.—Mr. C. Brandeis has asked for a charter for an electric street railway system; also a line between Nanaimo and Bracken in the newly discovered coal fields. It is proposed to derive power from the Nanaimo River Falls. Mr. Brandeis represents a Montreal syndicate.

WALLINGFORD, CONN.—The Wallingford Tramway Company will at once begin the construction of a line from this borough to Montowese, in the town of North Haven, where connections will be made for New Haven with the Fair Haven & Westville Railroad Company. The road will be 7 miles long, and the materials for it have been ordered.

DENVER, COL.—The Chaffee County Electric Light, Power & Railway Company has filed articles of incorporation with the Secretary of State. The company, which is capitalized at $500,000, is empowered to furnish electric power and construct street railway lines in Salida and its suburbs, and also to the towns of Buena Vista, Turret and Poncha Springs. Former United States Senator William E. Mason of Chicago, Ill., and T. F. Mason of Des Moines, Ia., will be prominently identified with the concern.

HOSCHTON, GA.—John R. Hosch, W. P. Dela Perriere, R. A. Hosch, J. E. Hill, H. J. Sill, G. Brasleton and L. F. Sill will apply for a charter to build an electric railway through Stone Mountain, Logansville, Hoschton, Jefferson, Commerce and Barnesville.

TOPEKA, KAN.—The Kansas City, Olathe, Lawrence and Topeka Railway Company has been incorporated here with a capital of $1,000,000 to build an interurban line between Topeka and Kansas City.

LEXINGTON, KY.—The Lexington & Suburban Railway Company has been chartered with a capital of $250,000, to build a 25-mile line from Mayview to Henry. Gustav Haerle, of Lexington, is interested.

EMMETT, IDA.—E. H. Dewey, of Nampa, is interested in a proposed electric railway between Emmett and Pearl.

LEWISTON, IDA.—W. H. Hill, chief engineer of the Lewiston & Southeastern Electric Railway, which is planned to run between Lewiston and Grangeville, states that surveys are completed and rights of way obtained, and that the work will begin at once. The line will be 86 miles long.

SPRINGFIELD, ILL.—Articles of incorporation have been issued to the Springfield, Petersburg & Beardstown Interurban Railway Company. The home office is at Petersburg, and the stock is placed at $2500. The incorporators are John S. Hurie, James S. Miles and Robert Bone.

BEARDSTOWN, ILL.—The Springfield, Petersburg & Beardstown Interurban Railway Company, with home office at Petersburg, has been incorporated with a capital stock of $2,600,000. The incorporators are John S. Hurie, James S. Miles and Robert Bone.

GALESBURG, ILL.—The McKinley syndicate has completed all the plans for its new power house, but has not yet announced the location of the plant. It will have a capacity of 4000 horse-power. The cost of the building complete will be in the neighborhood of $200,000. Mr. Duncan, of the syndicate, states that it is more than likely no contract will be let for the construction of the building, but that the syndicate will superintend the work. Some time ago a contract was placed with the Hamilton-Corliss Engine Company for two 1500-hp engines, and the Bullock Electric Company and the General Electric Company were awarded a contract for two generators. The Sterling Boiler Company will furnish four 400-hp boilers.

WABASH, IND.—The Indiana Central Traction Company has increased its capital stock from $50,000 to $200,000. The increase of capital will enable the company to complete the construction of two lines which it is now building.

FORT WAYNE, IND.—A conductor on the Fort Wayne & Southwestern Interurban Railway was killed a few days ago in a peculiar manner. He was using a portable telephone carried on the car and, it is stated, received an electric shock which caused his death.

MUNCIE, IND.—W. H. Miller, of Bluffton; Mr. Bonham, of Hartford City, and W. H. Maxwell, of Boston, have asked for a franchise in this county for an electric railway to connect Alexandria and Hartford City by a direct route, and also a spur to run from Gaston to Stockport, and thence to Muncie. The road will be incorporated as the Oil Belt Traction Company.

COALGATE, I. T.—The Lehigh Traction Company, chartered to construct an electric railway from Atoka to Coalgate, has let the contract for building the road from Coalgate to Lehigh, a distance of 8 miles, to the Mutual Electric Company, of St. Louis. The company will also establish and operate electric lighting plants at Lehigh, Phillips and Coalgate, having already secured franchises for that purpose. The power house will be established at Phillips, which is half way between the two terminals.

OELWEIN, IA.—The Oelwein & Hazleton Construction Company has been incorporated with $10,000 capital stock to build an electric railway to Hazleton, 8 miles in length.

PITTSFIELD, MASS.—Arthur H. Rice, of this city, has been elected president of the Hoosac Valley Street Railway Company. The directors will petition for authority to increase the capital stock by $100,000, making a total of $500,000, and to issue bonds to the amount of $300,000, making a total of $400,000.

BEVERLY, MASS.—The company that will build the proposed electric railway between Beverly and Haverhill will be known as the Beverly & Haverhill Street Railway Company. The capital stock of the company will be $20,000. The directors of the company are to be Joshua Hale, John Balch Blood and Albert W. Rantoul, of Newburyport; Clifford B. Bray, A. C. Lunt, Louis L. Dodge and John H. Moore, of Beverly, Mass.

BANGOR, ME.—The contract for the construction of the Rockland, South Thomaston & Owl's Head Electric Railway has been awarded to Michael Sorretto, of Boston. Howard C. Forbes, 4 State Street, Boston, Mass., is chief engineer.

FOXCROFT, ME.—The Railroad Commissioners have approved the petition of the directors of the Dover, Foxcroft & Sebec Lake Railway Company, of Foxcroft. The capital stock is $30,000. The directors of the company are I. L. Dickinson and George W. Taylor, of Lexington, Mass.; H. L. Jones, of Boston; A. H. Stanhope, of Dover; W. E. Parsons, A. W. Gilman, Willis S. Ham, of Foxcroft.

TRENTON, N. J.—The East Jersey Street Railway Company has been incorporated at Trenton with an authorized capital of $500,000 to absorb the East Jersey Traction Company, the Raritan Traction Company and the Perth Amboy Railroad.

TRENTON, N. J.—The Chicago & Oak Park Railway Company has been incorporated here with a capital stock of $9,200,000, of which $6,000,000 is common stock and $3,200,000 preferred. This company is organized to take over the property and franchise of the Chicago & Oak Park Railroad Company. The incorporators are Charles A. Boston, West Orange; William R. Sainsbury, Brooklyn, and John G. Quincy, Bronxville.

CORTLAND, N. Y.—The Cortland & Homer Traction Company is said to be considering the advisability of extending its line from Little York to Tully.

ALBANY, N. Y.—The Cohoes Railway Company has been incorporated with a capital stock of $120,000. This is a reorganization. The directors are J. N. Wallace, New York; Thomas I. Van Antwerp and Eugene Crawford, Albany.

TOLEDO, OHIO.—A new electric railway is projected between Toledo and Jackson. Stephen A. Foster, of Toledo, is general manager of the promoting syndicate.

KANE, PA.—The Ridgway Trolley Company is stated to be interested in the building of an electric railway between St. Mary's and Sheffield.

MEDIA, PA.—Indications now point to the early building of the Philadelphia Morton and Swarthmore Street Railway from Darby to Media.

BELLEFONTE, PA.—The Phillipsburg Electric Street Railway Company has decided to extend its line from Phillipsburg to Osceola Mills.

BERWICK, PA.—C. W. Miller, of Bloomsburg, states that the early building of an electric railway between Berwick and Nanticoke is an assured fact.

JOHNSTOWN, PA.—Surveyors are at work on the final survey for the Conemaugh Valley Railway Company line, which will connect Johnstown and Ebensburg. The right of way has been secured for the entire distance.

LEBANON, PA.—G. S. W. Brubaker, of Lancaster, has the contract to build the Hummelstown & Campbellstown Electric Railway. For the present the line will extend from Palmyra to Hummelstown.

ALLENTOWN, PA.—The Hanover Central Electric Street Railway Company has asked Bethlehem Council for a franchise. The company contemplates building from Bethlehem to Catasauqua, with a spur into Allentown.

CARLISLE, PA.—The Steelton, New Cumberland and Mechanicsburg Trolley Company has closed contracts for four 200-kw generators, four 350-hp Corliss engines and four 400-hp tubular boilers. Contracts for the rest of the equipment have also been made.

DONORA, PA.—The franchise ordinance of the Donora & Carroll Street Railway Company has been passed by the Council. The company has reorganized and elected Bert W. Castner, president, and Attorney O. S. Scott, secretary and treasurer. The officials are now securing rights of way.

FAYETTE CITY, PA.—The Buena Vista power plant of the Pittsburg, McKeesport & Connellsville Electric Railway, purchased by the Webster, Monessen, Belle Vernon & Fayette City Street Railway Company, has been dismantled and shipped to Belle Vernon, near which place it will be erected.

SAYRE, PA.—The Sayre Trackless Trolley Company, capital $60,000, has been organized with these officers: I. A. Williams, president; Louis Eighmey, vice-president; H. S. Winlack, secretary, and J. T. Corbin, treasurer. The plan of the company is to build here a line of trackless trolley as developed by the American Trackless Trolley Company, of Boston.

BEAUMONT, TEX.—It is reported that the street railway system of the Beaumont Traction Company has been purchased by an Eastern syndicate which is negotiating for systems of street railway in other cities of Texas. The new owners will, it is said, make additions and improvements to the local system.

TEMPLE, TEX.—The Belton & Temple Traction Company will build eight miles of line between Belton and Temple, and lines in both cities, making about 12 miles of line in all. Plans and specifications of the road are now in the hands of J. C. Hauser, of Lewistown, Pa., secretary of the company. The officers of the company are Samuel Watt, of Belleville, Pa., president; A. F. Bentley, of Temple, first vice-president; A. C. Mayes, of Lewistown, Pa., second vice-president; J. C. Hauser, of Lewistown, Pa., secretary and attorney; Calvin Green, of Lewistown, Pa., treasurer.

RICHMOND, VA.—The Traction Development & Securities Company, of New York, has recently closed a contract with the Citizens' Rapid Transit Company, of Richmond, Va., to build 10 miles of railway in the city of Richmond. The office of the company is at 74 Broadway, New York.

FAIRMONT, W. VA.—The Fairmont-Mannington Electric Railroad Company has organized with the following officers: T. W. Fleming, of Fairmont, president; Jesse T. Koen of Mannington, vice-president; Allison Sweeney, of Fleming, secretary; Charles E. Manley, treasurer.

CONWAY, WASH.—The Conway Electric Street Railway Company has filed a petition with the Railroad Commissioners asking for the right to increase its capital from $36,000 to $116,000.

EVERETT, WASH.—A franchise to build an electric railway from Snohomish to Cherry Valley has been granted to W. M. Snyder and associates by the County Commissioners. The same persons have applied for permission to build a line from Snohomish to Lowell.

NEW INDUSTRIAL COMPANIES.

THE ANYUN FUSE & ELECTRICAL COMPANY has been incorporated in Buffalo, N. Y., with a capital stock of $25,000. The directors are Daniel Haist, J. H. Holder and G. B. Bailey, of Buffalo.

THE NORTHERN ELECTRIC COMPANY, of New York City, has been incorporated with a capital stock of $10,000. The incorporators are T. J. Ryan, Lucien Barnes, Jr., and G. A. Schriefer, of New York.

THE MAGNETIC FLASHER ELECTRIC COMPANY, with a capital stock of $50,000, has been incorporated in Chicago to manufacture electrical devices. The incorporators are G. Discus, J. H. Minges and Frank Kramer.

THE AUTOCOIL COMPANY has been incorporated in Jersey City, N. J., to deal in electrical supplies. The capital stock is $100,000, and the incorporators are Charles T. Boyd, John J. Regan and John J. Baumann.

THE SOUTHERN ELECTRICAL COMPANY, of Nashville, Tenn., has been incorporated with a capital stock of $20,000. The incorporators are Felix Shwab, W. K. Webb, F. O. Watts, W. O. Vertrees and W. M. Bowles.

THE BREEGE MOTOR MANUFACTURING COMPANY, of Newark, N. J., has been incorporated to manufacture automobile engines. The capital stock is $10,000, and the incorporators are George A. Breege, Hugo Stummel and Joseph V. Weber.

THE WILLIAM WURDACK ELECTRIC COMPANY has been incorporated in St. Louis to do a general electrical business. The capital stock of the company is $10,000 full paid. The names of the incorporators are William Wurdack, John A. McClean and George R. Smith.

THE CENTRAL TELEPHONE CONSTRUCTION COMPANY, Toledo, Ohio, has been incorporated with a capital stock of $100,000. The company will do a general contracting business in the construction of telephone exchanges, plants and lines. The incorporators are E. L. Barber, Jas. S. Brailey, Jr., Jas. E. Brailey, Herbert A. Barber and Jas. C. King.

THE BANNER ELECTRIC COMPANY, of Youngstown, Ohio, has been incorporated with a capital stock of $100,000. The business is already established there and is one of the busiest institutions in the city. The incorporation was for the purpose of increasing the capital stock. The names of the incorporators, as given in the official document, are N. L. Norris, Thomas Carr, F. C. Kirschner, C. S. Crook and O. U. Cassidy.

LEGAL.

TELEPHONE DROP DECISION.—As we go to press, word reaches us that the Sixth Circuit U. S. Court of Appeals, sitting at Cincinnati, Judges Lurton, Severence and Richards coinciding, in the suit of the Western Electric Co. vs. the North Electric Co., in regard to the Warner drop, the opinion in favor of the North Company has been affirmed.

ELECTRIC POWER COMPANY ENJOINED.—Judge Anderson, of the Federal Court at Indianapolis, has granted a temporary injunction against the Elkhart Power Company to prevent it from disposing of any more of its bonds. The complainant is Lydia Owens who alleges that she is a large shareholder and that she has not been kept in close touch with the interests of the company, and that the merger of the several light and power companies of Elkhart was effected without her knowledge or consent.

PERSONAL.

MR. CHAS. E. WADDELL, electrical engineer, of Biltmore, N. C., recently visited New York, accompanied by his bride.

MR. H. W. POTTER, of the New York export department of the Westinghouse Electric interests, is back from a short trip to Panama.

MR. J. WATERSON, of Duban, Natal, South Africa, is now in New York, at the Murray Hill Hotel. He will place some orders for electrical machinery supplies.

MR. W. H. ST. JOHN, superintendent of the Yazoo City, Mass., light, water and sewerage plant, is preparing estimates on four miles of trolley line, with plant and equipment.

MR. RAFAEL SILVA, who is largely interested in concessions granted recently by the Mexican Government for the construction of hydraulic power plants, is now here at the Fifth Avenue Hotel.

MR. CLIFFORD WOOD, 52 William Street, New York, is about to proceed to Mexico and South America in the interests of various electrical equipment manufacturers and supply houses.

PROF. W. E. GOLDSBOROUGH recently delivered a lecture before the Pittsburg Technical Schools at the Carnegie Music Hall in that city, on the subject of "Electricity as a Factor in Expositions."

MR. C. H. HINES, recently electrical engineer for the Canadian Pacific Railroad, with headquarters at Montreal, has been visiting New York and has some special work on hand for the Erie Railroad.

MR. S. P. SHERRIN, president of the Indianapolis Telephone Company, accompanied by Mrs. Sherrin, has gone to Europe for a three-months' rest. Mr. Sherrin has done a great deal of work during the past year.

MR. R. O. WYNNE-ROBERTS, water engineer, Cape Town, South Africa, is in the market for electric stone drills and electric workers to be used for excavating rock and dressing face stones in a large dam in that part of the world.

CHARLES WHITNEY CARMAN & COMPANY, consulting electrical and mechanical engineers, have changed their address from 88 La Salle Street, Chicago, to 657 Railway Exchange. The firm is composed of C. W. Carman and M. C. Hartman.

MR. E. W. THOMAS, of Columbia, S. C., read before the meeting in Boston last week of the New England Cotton Manufacturers' Association an interesting paper on the electric transmission of power as illustrated in some of the practice in the South under his observation.

MR. EDOUARD ROTH, of Belfort, France, engineer with the Societe Alsacienne de Constructions Mecaniques, has arrived in this country on his way to St. Louis, where the corporation has an exhibit. He is also visiting some of the larger electric light and power plants.

MR. J. JENNINGS, the consulting engineer of the extensive group of South African mines controlled by Wernher Beit & Company is now on his way here from Johannesburg for the purpose of making some large purchases of electrical equipment, etc. He is expected here next week.

MR. E. W. BINKLEY, master signal electrician, U. S. Signal Corps, now at Denver, has been ordered to Seattle, Wash., to report to Lt. Col. James Allen for duty as assistant to the cable electricians on the U. S. cable ship "Burnside." Mr. F. P. Turner, of the same grade, now at Benicia Barracks, has been assigned to the same duty.

MR. S. G. McMEEN was the guest of honor at a banquet of Western Electric engineers and department heads, held at the Albion Cafe, Chicago, last week. Mr. McMeen leaves the Western Electric Company to go into consulting work, as previously announced, after nearly 20 years service of Bell telephone interests in the middle west.

MR. FRED W. WALTER has opened an office at 703 Citizens' Bank Bldg., Norfolk, Va., for the representation of leading lines of electrical apparatus and supplies. He will have in charge the interests in that region of the C. & C. Electric Company, the Stanley Electric Mfg. Company, the Bryan-Marsh Company and Pass & Seymour.

MR. C. P. STEINMETZ is the subject of the colored portrait calendar and biographical sketch issued by the Bullock Electric Mfg. Company for May in its series of "Great Men of Science and Engineering." Mr. Steinmetz was born in Breslau, Germany, in 1865, and came to America in 1889, joining the forces of the General Electric Company in 1893.

MR. JENKINS, of Jenkins & Co., Johannesburg, South Africa, will visit the United States shortly. The firm is a handler of American machine tools, electrical supplies, etc., and Mr. Jenkins will place several interesting orders while here. He may be found at the offices in the Centennial Building of the export commission house of Cadenas & Company.

MR. C. P. MARSH, of Charles Churchill & Company, Limited, the largest English handlers of American machine tools, etc., is now on a visit to this side with a view to closing some important contracts for Yankee labor saving devices to be installed in British arsenals and other Government plants. He is at the American Gas Furnace Company, 29 John Street.

MR. LYMAN C. REED has resigned from the Interstate Electric Company, of New Orleans, to enter into partnership with Mr. Wm. T. Spranley, also recently connected with the same company. The firm under the name of Spranley & Reed, will carry on business as electrical engineers and contractors with offices in Hibernia Bank Building, New Orleans.

MR. C. P. HILL.—Pittsburgh newspapers announce the engagement of Mr. Charles Phillips Hill, of the Doubleday-Hill Electric Company, to Miss Katherine M. Montague, of Baltimore, a cousin of Mrs. Alexander Brown, of that city. Mr. Hill is a great nephew of the late W. W. Corcoran, the banker who gave Washington the beautiful art gallery and collection bearing his name.

ROSENBAUM & STOCKBRIDGE announce their patent law and trade mark copartnership with offices at 140 Nassau St., New York City. Mr. W. A. Rosenbaum and W. M. Stockbridge are both well-known to the profession and need no introduction. The former has been practising in the electrical field for well nigh 20 years and has taken out hundreds of electrical patents.

C. OLLIVETTI & COMPANY, the celebrated Italian manufacturers of electrical measuring instruments, have removed from their old factories at Ivrea to new shops at 4 Via Broggi, Milan. The new plant has been built on much larger lines and equipped throughout with new machinery and apparatus. The new laboratory is specially adapted for the industrial calibration of high potential and large current instruments.

MR. S. R. INCH, electrical engineer and manager of the Missoula Light & Power Company, Missoula, Mont., was married in New York City on April 25 at the "Little Church Around the Corner," by Rev. Dr. Broughton, to Miss Margaret Bruce van den Broek, of London, England. The bride arrived from England on the "Etruria" on April 24 and Mr. Inch, who is an Englishman, came to this city to meet her and take her West.

MR. A. C. RAHE, manager of the Smith Storage Battery Company, on a recent visit to New York, stated that a few days prior he had secured two orders for installations of the Smith tray plate storage battery. One of these is for the Waverly Inn at Cheshire, Conn., and the other for the Ball & Socket Company, of the same town. The former installation replaces an isolated lighting unit, while the latter installation will be used as an auxiliary plant.

MR. OSCAR T. CROSBY, who lectured recently before a large gathering of members of the American Institute of Electrical Engineers and the New York Electrical Society on his explorations in Thibet has an interesting article in the May *North American Review*, on England and Russia in that country. He appears to regard the great, desolate table land and gigantic mountain chains as a permanent and perpetual barrier between the two leaders of European "assimilation" in Asia, and thinks China has some rights to be respected.

MR. HENRY W. POPE, of the special staff of the American Telephone & Telegraph Company, has been placed in charge of matters at the World's Fair, St. Louis, in connection with the fine Bell telephone exhibit there. Mr. Pope will hold this responsible position for the period of the existence of the Exposition. He will be glad to extend whatever courtesies are possible to members of the electrical profession, a very large number of whom he can claim as friends and acquaintances. Mr. Pope will assume his new duties at once.

MR. EUGENE ESTAVARD, a French engineer, has arrived from Paris and is now staying in New York City at the Astor House. He is studying electrical development here, and proposes also to make connections for the introduction of American specialties into France. He will be glad to hear from representative American manufacturers on the subject. Mr. Estavard has already had considerable experience in these lines in connection with one of the American firms formerly established in Paris.

BATES AND NEILSON, who have just announced their entrance into the consulting electrical engineering field, comprise Mr. Putnam A. Bates, late sales manager of one of the large electrical manufacturing companies, and Mr. John Neilson, until recently engaged in central station and railway work. These two active young engineers have some ten years' experience back of them and if perseverance, high principles and quality of work count for anything, they should make a success of their new undertaking. The offices of this new concern are at 42 Broadway, New York City. Mr. Bates has recently returned from an inspection trip to England, where he made a thorough study of manufacturing conditions and certain special subjects.

MR. A. M. HUNT, for several years connected with the engineering offices of San Francisco and up to last fall manager of the Independent Gas and Electric Company in that city, has, with Thomas Mirk, P. M. Hunt and J. M. Hunt, formed the firm of Hunt, Mirk & Co., with offices at 614 Mission St., San Francisco. Mr. Mirk was formerly chief engineer of the Independent Company's large electric station, while P. M. and J. M. Hunt have been engaged in machinery supply houses. The new firm has the Pacific Coast agency for Westinghouse steam turbines and engines, Worthington condensing apparatus, Laidlaw-Dunn-Gordon pumps, Keeler water-tube and fire-tube boilers, Patterson-Berryman heaters, etc., and in addition to the handling of this apparatus will act as contracting engineers, planning and installing complete power plant equipments. The firm starts out with excellent promise.

MR. JAMES DIETRICK, managing director of the United States & Nicaragua Company, is now here from Nicaragua in order to place large contracts which will include various electrical machinery and machine tools. The company, whose headquarters are in the Farmers Bank Building, Pittsburg, Pa., is to build some 350 miles of railroad in Nicaragua, so as to afford transportation to the vast coffee plantations in the interior of the country. Mr. Dietrick was formerly chief engineer of extensive gold mining properties in Mongolia and Manchuria for the development of which prior to the Boxer troubles he installed some three quarters of a million dollars of machinery, including electrically operated dredgers. He is expected in New York next week at the offices of H. A. Rogers, 19 John Street.

STERLING ELECTRIC AGENCIES.—C. S. Platt, 346 Broadway, New York City, is now representing the Sterling Electric Company, of Lafayette, Ind., in all eastern states. The Sterling Electric Co. would be glad to have him call on all telephone companies wishing to see a full line of telephone apparatus. D. L. Berry, of Grand Rapids, Mich., has just accepted the agency of the company in Michigan. He will handle a full line of apparatus and will be glad to show all telephone companies his samples. F. M. Ross, formerly of various supply houses, has accepted the position as a traveling representative in Indiana and Illinois. Fred E. Freers, now traveling in the western territory for the Sterling Company, carries a full line of Sterling high-grade apparatus, and would be glad to meet any prospective buyers.

MR. ALEX. HENDERSON, Master of Transportation of the Electrical Contractors' Association, sailed from Boston on April 30 for a three-weeks' trip to South America. He intends to return to Boston in time to attend the convention of the National Electric Light Association. He was accompanied by Mr. George W. Russell, the well-known electrical engineer and contractor, of New York City. Mr. Henderson says that the special train de luxe which will convey the electrical contractors to their convention at St. Louis in September will be the most handsome ever engaged and that accommodations are already being rapidly reserved. The train will be made up of combination buffet, smoking car, sleeping cars, dining car, ladies' car and library and observation car; and will have the best attendants procurable, including barbers, manicurists, hair dressers, etc. The contractors must be making money again.

PROF. A. G. BELL.—A special telegram from Washington, of April 30, says: "Alexander Graham Bell, who for the past year or two has been conducting experiments in aerial navigation at his summer home on Cape Breton Island, gave an exhibition of kite flying at Columbia, Va., this afternoon, before a number of Washington scientists. When Prof. Bell first announced his intention of testing his tetrahedral kites it was understood that he would send up a carrier that would demonstrate the feasibility of aerial navigation. Only experimental kites were used to-day, however, the biggest one being six feet high and of the same breadth. All of them sailed well in the light wind that prevailed, and the test was pronounced a complete success. After the kite flying was over, Prof. Bell received the congratulations of the scientists who had witnessed the tests and who wanted to know when the man carrier would have a trial."

MR. BION J. ARNOLD has been appointed consulting electrical and mechanical engineer for the Illinois Tunnel Company. This company has already completed some forty miles of subway tunnels underneath the streets of the business district of Chicago, and has installed an extensive automatic telephone service in the same district, carrying telephone wires in the tunnels. The problem which confronts Mr. Arnold is that of planning and installing a narrow gauge electric freight railway in these tunnels and arranging connections to the business buildings, freight depots, river docks, etc. It is proposed to perform a general freight collecting and distributing business, thus obviating a large portion of the teaming that now greatly congests the streets above. The necessary power stations, type of equipment, signalling and switching system, and method of conducting this transportation are all interesting factors in the problem. Mr. Arnold, it will be remembered, as municipal traction expert, recently made an extended study of the transportation problem in the down town district of Chicago, and his report to the city council upon that question is being followed out as the basis of a general scheme for relieving the surface congestion. He also holds the position of consulting engineer in the New York Subway enterprise.

MESSRS. CORY, MEREDITH & ALLEN.—Mr. A. M. Hunt having withdrawn from The Engineering Offices of San Francisco to form the firm of Hunt, Mirk & Co., that name has been abandoned and the remaining members, Prof. C. L. Cory, Wynn Meredith and W. H. Allen, will continue to do a general consulting engineering practice, paying especial attention to electrical, mechanical and hydraulic work. Messrs. Cory, Meredith and Allen will continue their offices at 331 Pine Street, San Francisco.

MR. MELVILLE E. STONE, general manager of the Associated Press, was given a banquet at Delmonicos, on April 30. It was attended by 300 well known people, including Messrs. H. D. Estabrook, A. B. Chandler and G. G. Ward. Ex-Postmaster General Smith said: "Mr. Stone has just returned with the brilliant laurels of the ambassador of American journalism to the Czar. He succeeded in inducing the Czar to remove the most rigorous censorship in the world, and we may regret that he did not extend his efficacious mission to the Court of the Mikado, for then we should be surer of having to-morrow morning, details of the battle fought to-day on the Yalu. One thing alone suffices to attest the great work which he did, and that is the fact recognized by every observer that the most intelligent, the most authentic, the most comprehensive dispatches which we have received have come from The Associated Press at St. Petersburg. The Associated Press is a mighty power. Under the management of Mr. Stone it has achieved a success and a breadth never before reached by it. It covers the world to-day with a breadth of sweep and a minuteness of grasp which are absolutely unparalleled. The old Associated Press presented simply the bones of the news. The Associated Press of to-day presents the life, the blood, the flesh, the color of our daily life, and in this it is doing a magnificent work. But in doing it, not alone The Associated Press, but even some of our best newspapers are not altogether free from the infection of that spirit of the new journalism which adopts somewhat sensational methods."

Trade Notes.

DALE COMPANY, Hudson & Thirteenth Streets, New York City, issues a special mail card as to its aluminum reflectors, collapsing collars, etc.

PITTSBURGH TRANSFORMER COMPANY, of Pittsburgh, Pa., issues a pretty little calendar for May and takes occasion incidentally to say a good word for its specialties in the transformer line.

FAHNESTOCK TRANSMITTER COMPANY has removed its offices to 132 Havemeyer Street, Brooklyn, near the entrance to the new Williamsburg Bridge, and with telephone call 3250 Williamsburg.

MECHANICAL APPLIANCE COMPANY, Milwaukee, Wis., issues a neat little folder of its Watson motor, shown attached direct to a ½-hp handkerchief laundry mangle machine. The motor is built in sizes from ⅛ up to 3-hp.

STANLEY & PATTERSON, INC., now announce the removal of their general offices and salesrooms to 40 Cortlandt Street, New York City. Their uptown store is at 329 Fourth Avenue, between Twenty-fourth and Twenty-fifth Streets.

CHASE SHAWMUT COMPANY.—Mr. W. S. Broue, the New York agent of this well-known New England concern has moved his local offices to the Bancroft Building, 3 West Twenty-ninth Street, which will be quarters also for the Alphaduct Mfg. Company which he represents.

THE ELECTRIC APPLIANCE COMPANY, Chicago, states that its customers are taking time by the forelock and contracting now for their next winter's supply of lamps. These contracts, the company declares, will be taken care of in A1 shape and filled with high grade Packard lamps.

THE WAGNER ELECTRIC MFG. COMPANY, of St. Louis, is issuing invitations to the electrical fraternity at home and abroad to visit it and use its offices as headquarters during the time of the World's Fair. The company will provide stenographic and other facilities for visiting friends.

THE NERNST LAMP COMPANY has established a branch office auxiliary to the Pittsburg district office at 537 Scofield Building, Cleveland, Ohio, in charge of Mr. J. C. Wright. This office will carry a stock of Nernst lamps and renewal parts, insuring prompt attention to all orders in this district.

SUMMER BREEZES is the title of a very dainty little pocket brochure issued by the Emerson Electric Mfg. Co., of St. Louis, telling all about its 1904 fans. The cover is excellent, the grass and woods all in green and a little Emerson fan supplying the breeze that ripples the foliage. Several styles of fans are illustrated.

SHEPHERD ENGINEERING COMPANY, of Franklin, Pa., has located its Boston branch office in the new Oliver Building at Oliver and Milk Sts. Mr. W. N. Clifford is in charge and prepared to handle the business of the New England territory right on the ground. In addition to the home office, it has established three branches, namely, at Chicago, Philadelphia and Boston.

AUBURN BALL BEARING COMPANY announces the removal of its main office and works from Auburn to 18 Commercial Street, Rochester, N. Y., where it will have an enlarged plant and increased facilities to produce Auburn ball thrust bearings and washers, propeller bearings, compound ball thrust and journal bearings, ball bearing hubs, power transmission specialties, steel balls, crucible steel discs, and many other well-known specialties.

STERLING ELECTRIC COMPANY, Lafayette, Ind., is receiving large orders for its various protector apparatus, especially its latest types, No. 250A and No. 250B, which a great many exchange managers have pronounced to be the finest of their kind. Its latest folder describes this protector at every point and can be had for the asking. The Sterling Company reports a very large sale of telephones of all kinds. Its new transmitter has been pronounced the best in the field.

GARVIN MACHINE COMPANY, Spring and Varick Sts., New York, has issued this month a very neat, handy and complete catalogue of its metal working machine tools. It is small 12 mo size, and contains over 200 pages and illustrates and describes fully its milling, screw, forming and tapping machines, monitor lathes, chucking lathes, drill presses, cutter grinders, hand lathes, etc., as well as a variety of special machinery. At the end are some useful tables, rules, etc., and a good index.

THE ELECTRICAL EQUIPMENT & SUPPLY COMPANY, 215½ Fourth Ave., Pittsburg, Pa., during the latter part of March secured the agency for the Yost Electric Mfg. Company. This representation covers the Western part of Pennsylvania. Since securing it, the socket business of the company has increased nearly 100%. Mr. J. H. Waugh, president and general manager of the company, believes that the business outlook is very bright for the concern, and is pushing things aggressively.

S. H. COUCH COMPANY, 156 Pearl Street, Boston, Mass., has issued a very handsome catalogue in its illustrated price list B. It is a complete and comprehensive pamphlet covering a large line of battery call single point telephones, battery call and magneto call intercommunicating telephones, magneto call telephones, and switchboard parts, telephone annunciators and instruments for hotels, apartment houses, residences, etc.; also transmitters, receivers, etc. The goods are set forth in full detail in this excellent price list.

THE F. BISSELL COMPANY, Toledo, Ohio, builder of switchboards for lighting and power reports that its trade on these boards has increased so largely that it has become necessary to extend its facilities and that it has recently placed large orders for additional stocks of marble and slate. It has found such a large demand for information and for ready prices on switchboards that at a cost of considerable money and labor it has prepared a new handbook on switchboards. This handbook will be sent free of expense to anyone interested in switchobards.

ELECTRIC CONTROLLER & SUPPLY COMPANY, of Cleveland, claims to be one of the first concerns ready in Electricity Building at St. Louis. Two of the specimens of the company's products are entirely new to an exposition. One of these is the direct action electric planer. The model at the fair is the first electric planer ever exhibited, permitting of the frequent reversals and changes of speed required in heavy steel work. Another novelty will be the lifting magnets perfected by the Electric Controller & Supply Company. These have been in successful use for some time, but have never before been exhibited.

GAS ENGINE SPECIALTIES.—Emil Grossman, of 298 Broadway, New York, is importing and manufacturing a number of gas engine and automobile specialties, chief among them being the Continental spark coil for gas engine ignition. This spark coil is the result of the long experience of a leading French manufacturer with devices of this kind and it has been pronounced most satisfactory by American manufacturers of gas engines, by whom it is widely used. In this coil both the primary and secondary windings are silk covered and the core is made from Swedish iron which possesses high magnetic qualities. The coil is made in all sizes and with case in any finish.

THE I. C. S. BUILDING AT ST. LOUIS.—The International Correspondence Schools, of Scranton, Pa., is represented at the Louisiana Purchase Exposition by a handsome building. The structure faces the plaza in the Model Village, which is one of the most interesting features of the Exposition. The lower floor of the building is devoted to a public exhibition of the plans and methods of the Schools, with specimens of the work of students. The second floor, furnished with all conveniences and comforts, is used as a post office, reading room, writing room, and, in fact, a rendezvous for I. C. S. students and their friends. The accounts of the rise of some of the I. C. S. students read like romance. Many of these experiences have been published in book form, and are exceedingly interesting. The book is entitled "1001 Stories of Success," and can be had for the asking.

THE METROPOLITAN ELECTRIC SUPPLY COMPANY, of Chicago, of which Mr. William McKinlock is president, has just moved to the Kelly Building at 184 Lake Street. The new building is directly across the street from the old and well-known location, and is equipped with electrical power, including fans, pumps and elevators complete. By means of the prism windows at front and rear, the salesroom, office and shipping room are a revelation of good light, even the basement stairs with the door shut being a great deal lighter than the corridor of many office buildings. Mr. Kinlock now has the exclusive agency for the Eureka flexible conduit, the Toerring arc lamp, and the Submerged motor. This latter consists of motor, propeller and rudder complete at the lower end of a metal post, which is used as the rudder post and is clamped by an adjustable device to the stern of a rowboat. Mr. McKinlock reports that the business doubled on the first day in the new quarters.

STEAM ENGINE CATALOGUE.—The latest example of the edition de luxe printing engraving which in recent years has been characteristic of certain lines of trade literature, is a catalogue of steam engines built by McIntosh, Seymour & Company, of Auburn, N. Y. The catalogue contains 68 oblong pages 9"x12" in size, about a third of which are given up to half-tone engravings of a kind, both in execution and printing, rarely seen outside of works of art and machinery catalogues. The engravings in the front part of the book illustrate details of the several types of McIntosh, Seymour engines, including some excellently executed line engravings. The second half of the book is given up to half-tone illustrations of large installations of steam engines supplied by the McIntosh & Seymour Company. To those interested directly in steam engineering this catalogue will have a high intrinsic value; while those interested in fine engraving and printing will find pleasure in looking through its pages.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, has at the St. Louis Exposition the most extensive and comprehensive exhibit that has ever been made of storage batteries and auxiliaries. It is located in Block 20, Electricity Building. A conspicuous feature is a map about thirty feet in height by forty-five feet in length, which, by an ingenious arrangement, shows the distribution of chloride accumulator installations throughout the United States. Illuminated glass jewels designate the locations and characters of the installations, whether for railway, central station, isolated lighting and power service, yacht plants, telephone installations, etc. There is set up in a model battery house a complete operating installation of chloride accumulators for railway service. Specimens of chloride accumulators ranging in size from a 61H type of cell to the smallest laboratory cells, are also shown, together with a complete exhibit of the Exide battery used for electric automobile work. In another section of the exhibit there are five types of switchboards, together with end cell switches, storage battery recording instruments, etc.

APPLICATION OF ELECTRICITY TO MACHINE DRIVING.—That the advantages of electrical operation of works and factories are becoming practically self-evident is demonstrated in the presidential addresses in engineering societies. Recently the president of the Sheffield Society of Engineers and Metallurgists said: "The engineer of ordinary ability found in electricity a simple means for remedying extravagances in works more readily than by any other method, and consequently welcomed its introduction. In large works the introduction of a central power station had been a means of doing away with miles of steam pipes connected with the various outlying engines, which caused great loss of economy from condensation. Boilers of high pressure were put down close to the central power station. These, with the electric distribution plant, gave an efficiency of, in many cases, more than 50 per cent. ahead of the old conditions of outlying steam engines. The wages of engine tenders were to a great extent saved, as the various motors throughout the works merely required periodical visiting at much less cost than the engine tenders wages added up to." Messrs. Johnson & Phillips, of Old Charlton, Kent, have sent us a handbook entitled "The Application of Electric Motors to Machine Driving," and a copy will be forwarded to those contemplating the introduction of electric driving in works, especially in the iron and metal, textile and printing trades.

NEW VEEDER TACHOMETER.—The Veeder Mfg. Company, Hartford, Conn., has just brought out in Form C a portable instrument for indicating revolutions per minute of dynamos, motors, shafting, etc. The readings are plainly shown by the height of the colored liquid in the indicator tube, in connection with the graduated scale. There is but one moving part in this instrument, viz., the paddle wheel in the centrifugal pump. The latter constitutes the lower part of the instrument. When the paddle wheel is revolved, the centrifugal force draws down the liquid in the reservoir and forces it up in the indicator. The bottom of the reservoir communicates with the center of the pump, and from the periphery of the pump there is a passage to the indicator tube. The vertical height between the surface of the liquid in the indicator tube and of that in the reservoir will be approximately proportional to the square of the speed of revolution. The reservoir is concentric with the indicator tube, so that a slight inclination does not vary the level of the liquid in the tube. The small handle at the front of the instrument is for throttling the passage from the pump to the indicator, to prevent the dancing or vibration of the column of liquid due to sudden fluctuation in the speed. Thus, if desired, the readings may be made "dead beat." A displacement plunger is provided for adjusting the zero level of the liquid. Pure alcohol, colored with aniline dye, is used. The standard length of scale is twelve inches. For laboratory work instruments can be furnished with scale 3½ feet high, or scales can be supplied with special graduations. The tachometer for general use has a ball thrust bearing on the end of the shaft.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED APRIL 26, 1904.

[Conducted by Rosenbaum & Stockbridge, Patent Att'ys, 140 Nassau St., N. Y.]

758,057. GROUND CONNECTION FOR ELECTRIC CONDUCTORS; Frederick P. Fuller, New York and John J. Walsh, Yonkers, N. Y. App. filed Oct. 16, 1902. A strap adapted to surround a pipe and carrying a clamp for the end of the wire to be grounded, is held in intimate contact with the pipe by means of a screw that bears against the pipe and exercises a tension upon the strap.

758,094. ELECTRIC, STEAM AND VAPOR GENERATOR; Thomas W. Neely, Marshall, Ill. App. filed April 23, 1901. Electrodes are placed in a body of water contained in a suitable boiler; the arc passing between them converts the liquid into vapor.

758,095. PROCESS OF GENERATING STEAM; Thomas W. Neely, Marshall, Ill. App. filed May 2, 1901. A process carried out by the apparatus above described.

758,106. TRANSMISSION OF ELECTRICAL IMPULSES; John S. Richmond, New York, N. Y. App. filed April 27, 1901. Two equal conductors forming the sides of a metallic circuit, combined with a ground connection for maintaining zero potential at the meeting point of the two conductors.

758,117. STEREOSCOPIC APPARATUS; Homer C. Snook, Philadelphia, Pa. App. filed June 22, 1903. An X-ray apparatus in which are employed a set of non-permeable stops so arranged between a fluorescent screen and the sources of radiation that two sets of images are formed, which are viewed by a similar set of non-permeable stops, whereby each eye sees a set of images formed by a single source of radiation, such images blending to produce the stereoscopic effect.

758,120. SWITCH; Henry Trumbull, Plainville, Conn. App. filed July 18, 1903. Details.

758,157. MEANS FOR PREVENTING ARCING BETWEEN COMMUTATOR BRUSHES; Elihu Thomson, Swampscott, Mass. App. filed May 29, 1903. A barrier of non-conducting material is placed in the space between the brushes.

758,164. RHEOSTAT; William C. Yates, Schenectady, N. Y. App. filed Aug. 16, 1901. A rheostat provided with two ranges of contact studs continuously connected in series relation and means for operating the one having the larger resistance units intermittently during the operation of the other.

758,165. INSULATION; Edmund E. Bechtold, Chicago, Ill. App. filed June

22, 1903. An insulating band attached to the edge of canopies to separate them from the wall.

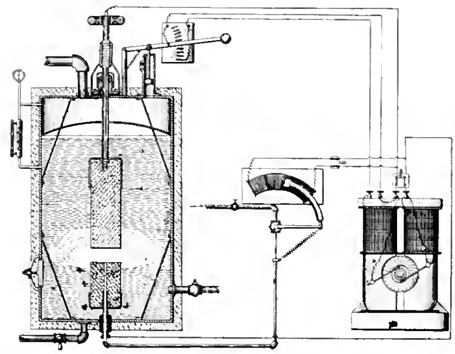
758,172. BLOW OUT FUSE; Fred B. Corey, Schenectady, N. Y. App. filed Sept. 2, 1902. The current carried by the fuse itself develops a magnetic field, the lines of force being carried by iron plates to intensify the field at the point where it acts on the fuse.

758,175. INSULATOR; Scott C. Cutter, Oswego, Ill. App. filed Dec. 11, 1902. A porcelain body having peculiarly shaped slots and openings to receive the wire.

758,116. SUPERVISORY SIGNAL APPARATUS FOR TELEPHONE SWITCHBOARDS; Edwin H. Smythe, Freeport, Ill. App. filed Sept. 14, 1903. (See page 875.)

758,179. SUPPORTING PIN FOR LINE INSULATORS; John D. Hilliard, Jr., Glens Falls, N. Y. App. filed June 16, 1903. To prevent the pin from breaking off, it is sustained by a conical sleeve resting upon the cross arm and bearing against a shoulder on the pin.

758,202. TELEGRAPH RECEIVER; Luigi Cerebotani, Munich, Germany. App. filed May 2, 1900. Electromagnets operate a shutter to allow a ray of light to strike a sensitized strip at intervals to photograph the signals thereon.



758,094. Electric, Steam and Vapor Generator.

758,205. MASSAGE MACHINE; John Graves, Milwaukee, Wis. App. filed Aug. 10, 1903. A massage machine consisting of a hollow handle, battery, conducting cap, a spiral wire roller and means for making a circuit from the cap through the roller.

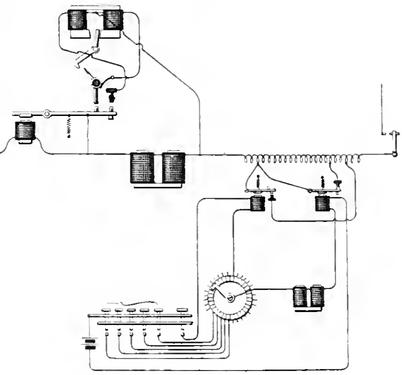
758,225. ELECTRIC MOTOR; Alexis Vanderbeck, Roseland, Kan. App. filed Oct. 10, 1903. A reciprocating motor in which the pole pieces are arranged so that unlike poles will attract and like poles repel at the same time.

758,230. TRAIN CONTROL SYSTEM; Harold E. White, Schenectady, N. Y. App. filed Nov. 20, 1902. The motors throughout the train are connected in pairs in such manner that the armature of each motor of a pair is in series with the field of the other motor of a pair; the armature and field combinations are then treated as if they were series motors by connecting them in series and parallel in the customary manner.

758,232. TELEGRAPH TRANSMITTER; Charles Adams-Rabdall, New York, N. Y. App. filed Aug. 25, 1902. Details.

758,236. ELECTROMAGNET; Harold W. Chamberlain, Brunswick, Me. App. filed Aug. 27, 1903. A two-limbed electro-magnet having an armature fulcrumed thereon in direct polar and magnetic contact therewith, and guiding means for the armature permitting it to be so fulcrumed during its entire movement, the magnet having one pole extending inward toward the other and situated under the inner side of the armature.

758,250. PRINTING TELEGRAPH; Clarence L. Healy, Newark, N. Y. App. filed June 16, 1903. Two stops are provided for an armature lever, one



758,250.—Printing Telegraph.

of which moves in proportion to the type carrier, and a detent for the type-carrier is set or not by the fact of the lever colliding with one or the other of said stops.

758,293. ELECTROMAGNETIC GEARING; Edward M. Bentley, Lawrence, N. Y. App. filed Dec. 2, 1903. A regulator for a dynamo electric machine acting to vary the effective rate of relative movement of field magnet poles and armature, comprising a pole shifter for the field magnet, giving the pole a rotation adjustable for regulation and supplementary to the relative mechanical movement of field magnet and armature.

758,297. RAILWAY SIGNAL APPARATUS; Clarence W. Coleman, Westfield, N. J. App. filed April 4, 1902. The signal is operated by fluid pressure from a tank arranged near the signal, from which the pressure is released to a pressure applying chamber in operative connection with the signals, by electrically operated valves.

758,303. ELECTRIC HEATER; Ernst Eckmann, Berlin, Germany. App. filed Aug. 15, 1902. Electric heater wires are stretched across the outlet conduit of a blower.

758,304. OFFICE DESK TELEPHONE; Alan Robb Fergusson, New York, N. Y. App. filed Nov. 16, 1901. (See page 875.)

758,306. ELECTRIC SWITCH; Alan R. Fergusson, New York, N. Y. App. filed Dec. 16, 1902. An automatic switch mounted on a pivoted arm which carries telephone instruments, is arranged to cut the instruments into and out of circuit with the changes in position of the arm.

758,324. SUPPORT FOR ELECTRIC CONDUCTORS; Fred C. Locke, Boston, Mass. App. filed Jan. 24, 1903. Details of a supporting clip.

758,328. DEVICE FOR SECURING INCANDESCENT LAMP FILAMENTS TO LEADING-IN WIRES; Albert W. W. Miller, South Orange, N. J., and Geo. P. McDonnell, St. Louis, Mo. App. filed July 3, 1903. Adjustable clamping devices mounted on a movable carrier, for holding the filament and leading-in wires in position while they are being connected.

758,342. SWITCH MECHANISM FOR ELECTRIC SIGNS; Frank S. Wahl, Buffalo, N. Y. App. filed July 14 1902. Details.

758,352. APPARATUS FOR ELECTROPLATING SOUND RECORDS; George K. Cheney, New York, N. Y. App. filed June 6, 1903.

758,355. TROLLEY WHEEL; James S. Fletcher and Donald H. Waters, Chicago, Ill. App. filed Sept. 3, 1903. Details of the mounting and contact devices of the wheel.

758,363. TELEPHONE RECEIVER; Miller Reese Hutchison, Norwood, N. J. App. filed Nov. 25, 1902. (See page 875.)

758,378. ALTERNATING CURRENT MOTOR; Ralph McNeill, New York, N. Y. App. filed Dec. 4, 1902. The armature circuits are each adapted to successively make contact with each of a number of energizing circuits, without being at any time short circuited upon themselves, and to always be in contact with at least one of the energizing circuits.

758,398. SIGNAL OPERATED BY CAR BRAKE BEAMS; Samuel N. Wilcoxon, Collingwood, Ohio. App. filed Jan. 13, 1904. When the brake is applied, the circuit to a special signal lamp on the car is closed, to notify a following car, in the dark, that the car ahead is being stopped.

758,415. TELEPHONE INSTRUMENT; Albert C. Christopher, Chicago, Ill. App. filed Feb. 3, 1904. (See page 875.)

758,430. APPARATUS FOR CIRCULATING LIQUIDS IN TANKS; George E. Dunton, New York, N. Y. App. filed Sept. 15, 1903.

758,445. TROLLEY HEAD; Peter D. Hean and John J. Eagan, Media, Pa. App. filed Dec. 26, 1903. Details of a construction to prevent the wheel from jumping from the wire.

758,468. ALTERNATING CURRENT SIGNAL RECEIVING APPARATUS; Greenleaf W. Pickard, Amesbury, Mass. App. filed Feb. 29, 1904. A relay consisting of two iron pole pieces with adjacent ends and an armature space, a pivoted armature having its free end held at the middle of the space and adapted to swing toward either pole, a coil surrounding one of the pole pieces, a magnet adapted to revolve around or past the other ends of said pole pieces and to induce opposite and cyclically changing magnetizations in the respective pole pieces.

758,478. ELECTRIC SWITCH; Joseph H. Resby, Nutley, N. J. App. filed June 25, 1903. Details.

758,485. RAILROAD SIGNAL OR ALARM; Robert F. Stuart, Logansport, Ind. App. filed Oct. 14, 1903. Details.

758,503. PROCESS OF FORMING VESSELS FROM SHEET METAL; Hermann G. Blevins and James E. Whittaker, Newcastle, Pa. App. filed July 1, 1903. The seams are electrically welded.

758,513. APPARATUS FOR CIRCULATING LIQUIDS IN TANKS; George E. Dunton, New York, N. Y. App. filed April 26, 1904.

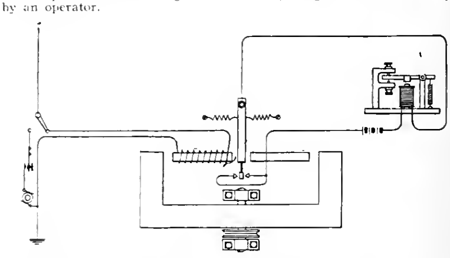
758,517. ART OF WIRELESS TELEGRAPHY; Lee De Forest, New York, N. Y. App. filed Sept. 21, 1903. The method of determining the distance to a sending station consisting in employing a choking influence of regulable amount in the receiving apparatus to thereby reduce the intensity of the signals received to a standard of comparison and in comparing the amount of such influence required with results obtained under known conditions.

758,527. SIGNALING AND OPERATING SYSTEM; Hedley C. W. Graham, Rochester, N. Y. App. filed July 9, 1903. A wireless transmission system is used to stop a train following too close upon another.

758,528. CURRENT COLLECTOR; John E. Greenwood, Utica, N. Y. App. filed May 16, 1903. Details of a double wheel trolley.

758,541. BLOCK SIGNALING APPARATUS; John A. Lehr, North York, Pa. App. filed Feb. 18, 1903. The signals received through a third rail arrangement are made to act successively on three different signaling devices, so that in case one should be out of order, the others will still respond.

758,589. LIGHT CONTROLLING SYSTEM; Harry Faltermayer, Philadelphia, Pa. App. filed Oct. 2, 1903. An apparatus wherein the lighting of the lamps of a sign to form various combinations is done automatically after a plate or card having in it certain openings, is once inserted properly by an operator.



758,468.—Alternating Current Signal Receiving Apparatus.

758,592. SAFETY TROLLEY; William M. Gruner and William C. Fink, Springdale, Pa. App. filed Nov. 5, 1903. Details.

758,594. ELECTRIC RAILWAY SIGNAL; William S. Jackson, Hoboken, N. J. App. filed June 30, 1902. Details.

758,598. TRANSMISSION OF ELECTRICAL IMPULSES; John S. Richmond, New York, N. Y. App. filed April 27, 1901. The art of electrical transmission consisting in producing in adjacent conductors electrical impulses simultaneously equal at contiguous points, but differing in that the potential of the one is above and that of the other below the maintained zero potential.

12,214. PROCESS OF OBTAINING TIN BY ELECTROLYSIS; Ernest Quintaine, Argenteuil, France. App. filed April 26, 1904.

CONTENTS.

Visitors from Abroad.

It is interesting to note that provision is being made betimes by the American Institute of Electrical Engineers for the reception of the visitors from abroad who will attend the Electrical Congress in September. It is true that the Institute has its annual meeting in this city next week, but interest is concentrated more particularly on the important work to be done later in the year; and we are encouraged to note that a number of European engineers and others may be expected. In fact, according to cable advices received from President Gray, of the British Institution of Electrical Engineers, its contingent is already one hundred strong, and other large delegations are known to be preparing for the voyage. All this promises great success for the Congress, and is also to be hailed as a sign of a desire to become better acquainted with this country and its development. American engineers are far better acquainted with Europe than European engineers are with America, and it is for the benefit of all that the inequality should be redressed. There cannot come too many from abroad this year, and the heartiest welcome awaits every one. In fact, it promises to be so hearty we may have to mitigate its rigors a bit for those who are not accustomed to jump around 500 miles a night in sleeping cars.

Street Railway Municipal Ownership.

The recent balloting in Chicago on the subject of municipal street railway ownership and operation will doubtless lead to a general agitation of that issue, at least where politicians think that it may be to their advantage to bring it into the field of practical politics. We have some sympathy with the general feeling of irritation that can be aroused by a prolonged wrangle with transportation companies punctuated by strikes and riots, but the merits of the controversy which led to the action in Chicago are neither here nor there; they are utterly inconsequential in the present issue. Nor do we consider the failure or success of municipal tramway enterprises abroad of any particular consequence. If they have uniformly failed, so much the worse for them; if they now and then succeed it is to the personal credit of the administrators rather than to the glorification of the principle. We are not so deeply rooted in pessimism as to hold that nowhere upon the orb of the earth can a municipal transportation enterprise be operated with honesty and economy, but we do submit that the past record and present character of municipal administration in Chicago and in the cities of this country apt to follow in the footsteps of that city, are such as to foredoom the result of any experiment made.

The current demand upon tramway companies is in its essence a demand for reduced fares. The several propositions brought to the front may bear either directly or indirectly upon that purpose, but they all come ultimately to the same issue. Adequacy of the accommodations is sometimes a subject of discussion, but upon this matter the tramway companies and the citizens soon meet upon common ground and work together. Attempts to lower the customary five-cent uniform fare meet, however, with determined opposition. The difference between four cents and five cents is on its face trivial, but it aggregates twenty per cent. of the gross receipts of a tramway company, and a three-cent fare would cut the gross receipts forty per cent. In theory some allowance would have to be made for increased traffic at the lower fares, but it has yet to be shown that the gain would be material. On the relatively long hauls there is small reason to expect much increase of patronage, and even on the short hauls the gains would be small unless a complete zone system with graded fares were adopted, and this in an American city would be unpopular. There are few commercial enterprises that can stand a cut of even twenty per cent. in their gross income unaccompanied by any reduction of expenses. Even granting that some urban roads are grossly overcapitalized and that their earnings upon the actual cash invested are very large, yet a loss of twenty to forty per cent. in gross earnings would be disastrous. The zone system will probably have to be tried sooner or later as a means of cutting fares, but we think a very short experience with it will be sufficient for the American public.

As to municipal ownership itself, its only excuse for being is a desire to obtain for the public in one form or another the profits of the enterprise. Practically it stands for reduced fares with all the financial difficulties thereby implied. Its real reason for existence, however, is far less innocuous than its nominal excuse. Graft is written large all over any municipal tramway scheme. As a source of jobs and miscellaneous swindling, a municipal tramway in an American city would be in a class quite by itself. The number of employees involved is large, the annual supply bills are large, and the pickings and stealings would be upon a scale of magnificence difficult to equal. And does any sane man suppose that such opportunities would be neglected even for a single season? All that dishonest officials now get from the bland almoners of corporate bounty would be only as a drop in the bucket compared with the results of municipal ownership in any American city. If Chicago really desires to inaugurate a carnival of graft the preliminary steps now taken are emphatically in a suitable direction. Fortunately for Chicago and the country at large, further steps will be more difficult, and there will be time for the sane second thought of honest citizens to come to the rescue. We cannot seriously believe that the metropolis of the West will place itself definitely upon a platform of which "Millions for Graft" is the one conspicuous plank.

Electric Automobiles.

It has not escaped general notice that in the large automobile parade held in this city recently, a considerable proportion of the industrial vehicles were of the electric character. In other words, nearly all of the 80 or 90 commercial vehicles in line were of the electric type, and it is matter of common observation that very few of the industrial automobiles seen hereabouts are other than electric. In this category we do not include the cabs and hansoms of the electric type, which are also so numerous, and which apparently have very little competition from gas or steam automobiles of the same type. Whatever may be the status of electricity in regard to pleasure automobiles, it certainly seems to be holding its own in doing the work of the world, and in the long run we think that after some of the craze for fancy automobiling has died out this condition will not be altogether to the disadvantage of electricity.

Meantime we believe that the central stations in this country can do a great deal to foster and encourage the use of electric vehicles, not only in supplying current, but in operating vehicles of this character themselves. We are glad to call attention to the fact, for example, that the New York Edison Company has in its own service just about a score of these vehicles, not all but mostly of the industrial type, and all of them employed in facilitating the service of the company; some in transporting the officials and inspectors from point to point; some in handling lamps and supplies; some in conveying heavy material, and some in such work as hauling in underground cable. In fact, a case came to our notice recently where 4,400 ft. of high-tension cable was safely hauled in in a ten-hour day and 500 ft. in 18 minutes. It is by applications of this kind that central station companies not only give an admirable example to the public, but tend to build up their own business in a department which should afford a field of very large consumption of current. The Boston Edison Company has also done admirable work in this field, and we believe the convention in that city this month could well devote, and profitably, an hour or two to the general subject.

Harnessing the Hudson.

We are now glad to be able to give our readers, supplementing data given last year, a rather detailed account of the immensely interesting power developments in the region around Albany. The generating plants for this important network, distributing power to all the electric systems in an area of more than 600 square miles, have already been fully described in our columns, and the present article relates merely to the utilization of that power at various points in the territory reached. This work, involving the displacement of steam in stations doing all sorts of work and long established, required no small amount of engineering ability, for it is always easier to lay out a great system *de novo* than to adapt a new transmission plant to the various exigencies of a heterogeneous electric service already long in business. In such a task there are likely to be required a wide variety of compromises, and the warring demands of various customers are apt to stimulate the ingenuity of the engineer. The details of a group of sub-stations make instructive reading, but they seldom pulsate with the vital interest that inspires editorial comment. In the mass, however, one can find occasional bits that rise above the plane of constructive common-place and illustrate methods or tendencies which have more than a local importance. In the present instance there are three salient features of the system which separate it from many recent plants which we have described. In the first place the frequency is 40 periods, as in the original Mechanicville station, a periodicity which is unusual in this section of our country. Second, there is a considerable use of high-voltage, three-phase cables not only underground, but for crossing the bed of the Hudson. And finally there is in the sub-stations a very wide use of synchronous motors, in utter contravention of the practice in some plants of the past few years.

As regards the question of frequency, the three-phase system started out both here and abroad at a periodicity of 40 periods to 50 periods, in the days when ordinary alternating plants ran at 120 periods to 130 periods. The lower frequency enabled one to run incandescent lamps admirably and gave also good motor service. At 50 periods, certainly, alternating arc lamps could be used with good results and the frequency was well suited to mixed service. But a new line of transformers was required, and presently in a rather rash attempt to make the old transformers answer for the new apparatus everybody had a try at a frequency of 60 periods to 70 periods. This process of putting new wine into new bottles led to the customary result, but by the time a new line of transformers had replaced the misused ones which had burned out, many polyphase plants had gone in at the increased frequency. By this time, too, the rotary converter was in full swing, and a sharp demand had sprung up for low-speed motors. Under the pressure thus created, inasmuch as rotaries and low-speed motors are not easy to build at 60 periods or so, a new line of apparatus at 25 periods came into use. Just why this frequency which is just too low for the advantageous working of incandescent lamps was chosen it is hard to say—possibly because some engineers thought that in the rotary converter they saw the finish of alternating distribution circuits. Now, the plant under consideration has come back to first principles at 40 periods, and apparently without inconvenience, save in the matter of frequency-changing for some of the arc service; and merely as a matter of saving changes, it would appear, for part of the incandescent circuits. Rotary converters up to 600 kw output are operated at 40 cycles and we do not imagine that the slightest trouble will be experienced with them. It is difficult to predict the trend of frequency, especially since alternating-current motors for railway service are beginning to be introduced, but it certainly has been demonstrated that it is unnecessary to go to extra low frequency merely on account of rotaries.

The cable feature in this plant is of particular interest. It was necessary to use underground lines in going into Albany. This was a comparatively straightforward job, and cables at the pressure used, about 10,800 volts, had already been made; but, still, the performance of these paper-insulated, lead-covered cables at so high a pressure will be exceedingly well worth watching. We are inclined to the opinion that they will answer the purpose well. In entering Troy it was necessary to cross the Hudson, and a choice had to be made between a high span from steel towers and an underwater cable. Just what determined the choice of the latter we are unable to state definitely, but we are glad that the cables were chosen, if merely for their value in experience. Like the underground cables, these are paper-insulated, lead-covered cables, but armored with galvanized iron laid over jute. Barring danger from lightning, lessened by careful local protection by lightning arresters, the cables run no especially severe risks, and their performance in steady use will be immensely instructive. So little is known about the working of high-tension cables under water that every instance of their use is of direct importance to the art.

Finally, we must note the regular use of synchronous motors in the various sub-stations. Two or three years ago the trouble from "hunting" in these machines had the bulk of the engineering profession pretty well scared, and many enormously big induction motors were being installed to avert the difficulty. The big induction motor is a beautifully simple machine, but it is not altogether a good thing to encourage in a large transmission system, and we are glad to see that the synchronous motor has been mastered sufficiently to allow its free use in situations where it can be of value. One other point in this system awakens a lively interest—the use of automatic three-phase regulators in one of the sub-stations. It is only recently that such apparatus has been put out, although it has been greatly needed. If thoroughly successful, and there is no good reason why it should not be, one of the standing difficulties in long-distance power transmission will have been obviated. Hand regulation is effective enough, but good automatic regulation is greatly to be desired for all classes of service.

THE MAGNETIC OBSERVATORIES OF THE UNITED STATES.

The United States Treasury Department, controlling the United States Coast and Geodetic Survey, has recently issued a very entertaining buff book marked "Appendix No. 5 of the Report for 1902," reciting the conditions of the United States magnetic observatories in operation July 1, 1902. Careful records of terrestrial magnetic elements have been compiled during the last three centuries. The results acquired are of great scientific value, and indicate the possibility of important utilitarian application in the future, when they shall be better understood and interpreted. A few years ago the capitals of nearly every important country had a magnetic observatory in full operation, recording from moment to moment the direction and intensity of the earth's magnetism. Thus, London had Kew Observatory, the United States had the Washington Naval Observatory, Canada had the Toronto Observatory, etc.

Alas for the mutability of magnetic forces! The all-invading trolley car has been more fell than hunger, anguish or the sea. The magnetic observatories have been put out of business by the central stations. Kew, Washington, Toronto and Paris have all banished their observatories to fresh fields and pastures new. Kew fought hard against the deadly trolley and invoked Parliament and City Council, but finally packed up her instruments. Numerous other observatories have followed a similar flight. The magneticians all ask the same question: "Where can we erect our altars and set up our instruments out of the ruthless reach of the desecrating trolley?" The Emperor William of Germany, reposing upon the divine right of kings and kaisers, uttered a royal decree forbidding trolley cars to come within 16 km. of his Potsdam observatory. This solved the difficulty for the two observers and the six suspended magnets at Potsdam. But the various thousands of disinterested German citizens in the neighborhood protested, in favor of rapid transit. According to the report, there has been some talk of taking back the decree and taking away the observatory. The United States has joined in the exodus. The Washington Observatory gave up the struggle. There are now four United States magnetic observatories that the experts consider safe for the time being from the trolley cars. One is in Sitka, Alaska, "near the new Russian cemetery," a quiet, remote place. The second is "on an immense coral plain" 20 km. west of Honolulu in the Island of Hawaii. The third is in Baldwin, Kan., 21 km, in an air line, south of Lawrence, Kan. This, however, is but a temporary site, and, if trolleys should come the equipment can be shipped quickly. The fourth is at Cheltenham, Md., on the grounds of the Maryland Reform School. Two local passenger steam trains pass Cheltenham daily. The report states that the land in this region, while in a flourishing condition before the civil war, when slaves were available for tilling the soil, is now so undesirable that so far as can be seen at present, there will be little inducement to run electric car lines into this region. The civil war was thus evidently not in vain from one special viewpoint.

Great pains have evidently been taken with the construction of the buildings for these observatories, so as to maintain a nearly uniform internal temperature at the magnetographs. This thermal insulation has been provided by using multiple walls and large thicknesses of dry sawdust. Three thousand sacks of sawdust are stated to have been used in the Sitka Observatory alone. The thermograph records for Cheltenham Observatory inside and outside the building during a week show that while the external range of temperature during that time was about 50°, the internal range was about 1°. It is interesting to observe that the apparatus employed for making and recording the observations differs but little from that employed thirty years ago. Of course, it is only reasonable to expect that observations and apparatus may crystalize after three centuries of use. Moreover, there is one advantage of uniformity of type, in that all observations may have a greater degree of approximation. On the other hand, it seems strange that portable magnetometers, on electromagnetic lines, have not come into general use for rapid work in traveling. The absence of a proper scientific terminology in the magnetic c.g.s. units reveals itself in the work of the department, which has created a unit and name of its own. The earth's horizontal intensity, if interpreted as $\mathcal{H}$, a magnetic force, would be expressible in gilberts-per-centimeter; or, if interpreted as flux density $\mathcal{B}$, would be expressible in gausses. Not having the gilbert-per-centimeter, the tabular results are "expressed in gammas." The gamma, a unit of magnetic intensity, invented and christened by the department, is 1/100,000 of one gilbert per centimeter. The results are expressed, as a rule, to five significant digits, and are probably conveniently written in terms of a unit of that particular magnitude. A more conformable method, with respect to other branches of magnetic science, would be to shift the decimal point, and express the result in milligilberts, or microgilberts-per-centimeter as $\mathcal{H}$, or if the values may be interpreted as $\mathcal{B}$, to write them in milligausses or microgausses. The adoption at the 1900 International Electrical Congress of the name gauss to designate the c.g.s. unit of flux density, renders particularly inappropriate the invention and use by a government bureau of a new unit and new name. That it will survive in view of the international action above noted is improbable, and in the meantime it will give rise to confusion.

National Electric Light Association.

Mr. Charles L. Edgar, president of the National Electric Light Association, spent two or three days in New York last week making final arrangements for the convention to be held in Boston May 24-27. Owing to President Edgar's energetic methods 25 papers and reports are now in type, and it is expected that copies will be distributed to those members who have announced their intention of attending the meeting, reaching them before they leave home, and thus enabling them to prepare themselves to discuss the papers intelligently.

Mr. Hodskinson, chairman of the committee on hotel accommodations, has succeeded in getting replies from every member company, stating whether or not a representative would be in attendance, and from these replies it is estimated that the representation will be far in excess of that at any previous meeting. Most systematic arrangements have been made for the reception and registering of delegates, and a plan of distributing and looking after the papers has been formulated which promises to make that part of the convention routine run very smoothly.

Heavy Travel in Greater New York.

A report of the New York State Railroad Commission covering the year ending February 29 shows the number of cash passengers and also the number of transfer passengers carried by the local traction systems as follows:

Interborough, 273,133,242, increase 37,318,852; car mileage 60,730,337, increase 12,870,859.

New York City Railway (Interurban), 397,644,829, increase 144,311. On transfers there were 166,310,453 passengers carried, an increase of 11,435,049; car mileage 62,412,527, increase 954,666. The number of passengers carried in the first three quarters of the year increased 5,129,287, but the loss in the winter months practically offset this.

Brooklyn Rapid Transit, 285,725,986, increase 23,280,423. On transfers 55,146,001 passengers were carried, an increase of 3,772,959; car mileage 54,394,315, increase 3,025,769.

Coney Island & Brooklyn, 33,129,812, increase 967,765. On transfers 6,016,455, increase 88,063; car mileage 6,212,762, increase 43,854.

Union Railway, 21,273,870, increase 1,998,543.

The chief item of interest is the rapid gain on the Interborough elevated system as compared with stationary conditions on the Interurban surface system in New York. Probably the latter will improve when the fearful mess and obstruction of the underground railway work is cleared out of the way.

Annual A. I. E. E. Meeting.

A departure will be made this year from past practice in relation to the annual or business meeting of the American Institute of Electrical Engineers, which will have somewhat the character of a general meeting. The meeting will extend over two days, with a programme covering the morning, afternoon and evening of the first day and the morning and afternoon of the second day.

The first session will be called to order at 10.30 A.M. Tuesday, May 17. During the morning the following papers will be presented: "Predetermination of Sparking in Direct-Current Machines," by W. L. Waters; "Effect of Self-Induction on Railway Motor Commutation," by E. H. Anderson; "On the Calculation of Line Batteries," by W. E. Winship.

At 1 P.M. there will be a luncheon, followed by a visit to the Rapid Transit Subway. At 8.15 P.M. a meeting will convene at which the annual reports will be read, announcement made of the results of the annual election, to be concluded by a paper by Mr. B. G. Lamme on "Data and Tests on a 10,000-Cycle Alternator."

At a morning meeting on Wednesday the following papers will be presented: "Notes on Fly-Wheels," by H. H. Barnes, Jr.; "The Single-Phase Induction Motor," by Prof. W. S. Franklin; "Wave Form Variations of a Long-Distance Line," by Prof. Geo. H. Rowe. At 1 P.M. there will be luncheon, after which the library and technical laboratories of Columbia University will be visited.

It is announced that the general meeting of the Institute will be held at the St. Louis Exposition during the week ending September 17, 1904, at which no unsolicited Institute papers will be presented or discussed.

Convention of Texas Electrical Associations.

The Southwestern Gas, Electric & Street Railway Association and the Southwestern Electrical Association held a joint annual convention at Dallas April 25, 26 and 27, at which it was decided to unite the two organizations under the name of Southwestern Electrical & Gas Association. Those eligible for active membership in the new association are companies, firms or individuals engaged in the manufacture of gas, generation of electricity, operation of electric railways, telephone exchanges and telegraph lines. The officers-elect of the new association are as follows: President, J. F. Strickland, of Waxahachie; secretary, F. E. Scovill, of Austin, and treasurer, A. E. Judge, of Tyler, Tex.

Most of the first day's session was occupied with discussions as to the benefits and evils of telephone competition. This discussion grew out of a paper read by Mr. J. E. Farnsworth, general manager of the Southwestern Telegraph & Telephone Company. Mr. James Moroney, of Dallas, favored independent companies and pointed out the benefits to be derived through their service. At the conclusion of the afternoon session the members were tendered a trolley excursion around the city. In the evening various entertainments were provided for the visitors. Forty candidates were put through the initiation of the "Sons of Jove," after which a smoker was held.

Among the papers announced on the programme were "Municipal Franchises," by John W. Shartell, president of the Metropolitan Railway Company, of Oklahoma City, and "Advantages of Combination of Gas & Electric Plants," by R. R. Stitcher, of the Cleburne Gas & Electric Company, of Cleburne, Tex. Mr. H. F. MacGregor, vice-president of the Houston Electric Company, read a paper entitled "Accidents and the Damage Suit Industry." Mr. MacGregor referred to the growing evil of damage claims based on the slightest pretext and frequently on fraud, and gave some advice as to the management of this department of companies. He stated that the increase in the amount of damages paid for the work of damage suit bureaus in magnifying slight injuries and prompted fraudulent claims until finally the matter has attracted the attention of the Railroad Commission of the State of Texas to the injustice. Every member of the Association, he said, should enlist in the campaign of exposure of fraudulent claims. Corporations have suffered from the administration of justice in Texas, not so much from the intent of juries not to reach the justice of the case, but from perjured testimony that creates confusion; and the inaction of the judges.

Western Union and the Poolrooms.

The relations of the Western Union Telegraph Company to the pool rooms which are carried on contrary to law in New York, but which it furnishes a special service, continue to attract considerable attention and excite comment. President Clowry, of the company, in a public statement, says: "In view of recent occurrences I have to say that I do not believe any fair-minded person will suppose that the Western Union Telegraph Company would willingly become party to any criminal undertaking. While we cannot put ourselves in the attitude of passing upon the morals of the people for whom we transmit messages, or to whom we lease wires, we are quite ready to co-operate with the constituted authorities in their efforts to suppress crime, and we will go just as far in the direction as, under the advice of our counsel, we are permitted by law to go. Surely, no one will expect us to enforce one law by breaking another law. If the authorities will give us evidence upon which we can prudently act, they need have no fear that we will not aid them. Whenever those charged with the enforcement of the law will furnish this company in writing with the names of persons who are engaged in keeping unlawful pool rooms, and specify the places where the pool rooms are located, and state that they have decided to take action to close them up, if they request the telegraph company to cease the transmission of intelligence to such places we will promptly comply with such request, even though the public authorities should prove to be mistaken and the telegraph company be thereby involved in litigation and liability."

The attack is now being leveled at the New York Telephone Company as well, on the ground that it also gives service in the pool rooms; and the accusation is made that the attitude of Col. Clowry is hypocritical. Several of the papers print in "caps" the names of the directors of both companies, as men willing to make a special profit out of business with gambling hells.

Hudson River Power in Albany, Troy and Schenectady.

ELECTRICAL supply in Albany and Troy, N. Y., is now drawn from Spier Falls on the Hudson 40 miles up stream, and from the falls at Mechanicville, 15 miles away. This transmitted energy is supplied to the local companies in Albany and Troy by the Hudson River Water Power Company, and the contracts call for the immediate delivery of a maximum of 6,000 hp in each city.

The water power plants at Spier Falls and Mechanicville, and the transmission lines, switch houses and sub-stations of the Hudson River Water Power Company have already been described in previous issues of the ELECTRICAL WORLD AND ENGINEER, dated June 27, October 24 and 31, and November 7, 1903.

Two three-phase transmission lines from Spier Falls, and one three-phase line from Mechanicville, run to the Watervliet sub-station of the Hudson River Water Power Company, which is just across the Hudson from the city of Troy. Each of these three circuits is made up of three bare solid copper wires, size 3/0 B. & S. gauge. Energy delivered to the line at Spier Falls at about 30,000 volts reaches the Watervliet sub-station 35 miles away at about 26,500 volts, and the current from Mechanicville comes into the same sub-station at approximately 10,800 volts. Transformers at the Watervliet sub-station reduce the 26,500-volt current from Spier Falls to the 10,800-volt pressure, and the energy from both Spier Falls and Mechanicville is then transmitted from Watervliet at this latter voltage to the local sub-stations of the lighting and traction systems in Albany and Troy. The energy from Spier Falls is reduced in pressure from 26,500 volts to 10,800 volts at Watervliet because it is necessary to cross the Hudson River with a cable in order to reach Troy, and to run underground in entering Albany. It was not thought desirable to use as high a pressure as 26,500 volts in the submarine and underground cables necessary for these purposes. At Mechanicville the current is developed at a little above 10,800 volts, and the reduction of the 26,500-volt current to this lower voltage at Watervliet brings both sources of energy there to the same pressure.

At the Watervliet sub-station the equipment includes nine transformers rated at 1,000 kw each, which are arranged in three groups for the transmission circuits above mentioned, and reduce the voltage from 26,500 to 10,800. From Watervliet two 10,800-volt, three-phase overhead circuits run to another sub-station of the Hudson River Water Power Company about four miles distant near the city limits of Albany and called the Albany sub-station. The object of this sub-station is to regulate the pressure of the two 10,800-volt circuits, connect their overhead wires with underground cables, and to reduce the voltage of a part of the energy for local distribution. This sub-station is 55 ft. 9 in. by 31 ft. 6 in. on the ground, partly one and partly two stories in height, and has a basement underneath its entire area. In structure the walls of this building are brick, the floor of the basement concrete, the upper floors concrete on steel I-beams, and the roof tile, also supported by I-beams.

The central portion of the basement forms an air pressure chamber over which the transformers on the first floor are located. On this first or main floor there are also located two so-called I. R. T. automatic regulators of General Electric make rated at 300 kw each. Each of these regulators is connected to one of the 10,800-volt, three-phase circuits, has capacity to raise or lower the voltage thereon by 7.5 per cent., and is designed to maintain a constant voltage to within one-half of one per cent. Room is provided over the air pressure chamber for nine transformers of 500-kw each, these transformers to be arranged in three groups and reduce the voltage from 10,800 to 2,300 for local distribution. From these transformers the 2,300-volt circuits lead to a switchboard on the same floor that controls the local lines. Two motor-driven blower sets occupy a part of the floor space over the air pressure chamber, and maintain the pressure that forces air through the transformers and the I. R. T. regulators.

In front the sub-station is two stories high above the basement, and the two-story portion is 10.5 ft. wide between 12-in. brick walls and its length occupies the entire width of the building. Into this front end of the sub-station, which is thus separated by a brick wall from the remainder of the building, come the bare overhead transmission lines. For the entry of these lines nine circular openings,

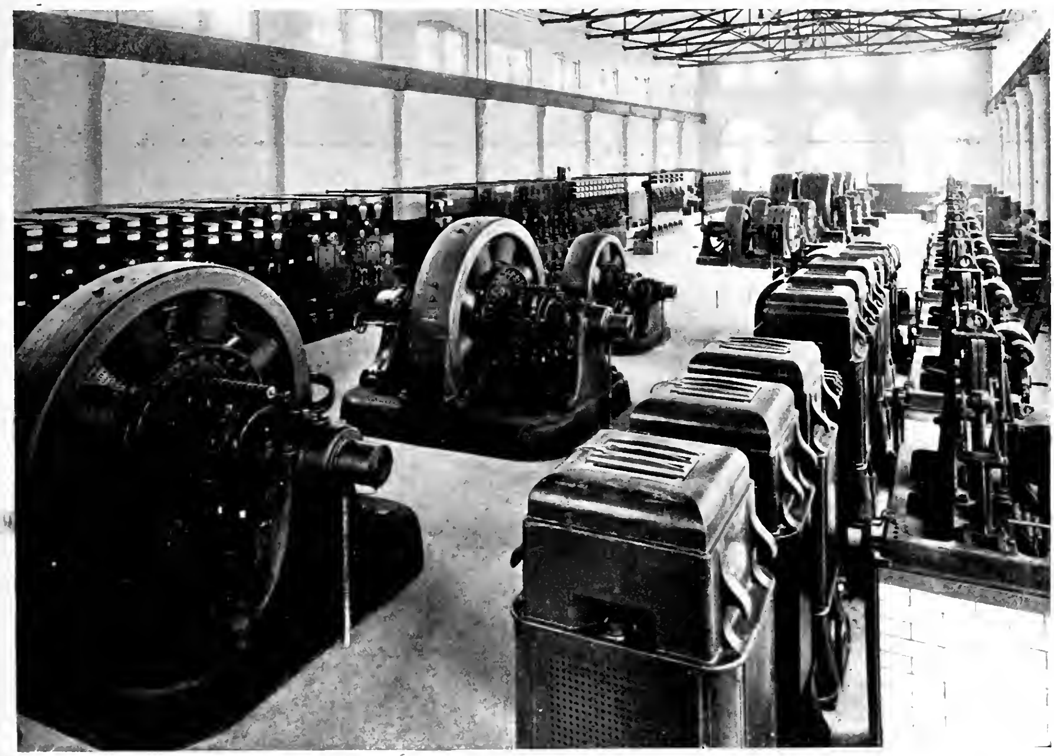

FIG. 1.—VIEW OF INTERIOR OF SUB-STATION OF SCHENECTADY RAILWAY, SCHENECTADY, N. Y.

each 15 in. in diameter, were made in the brick wall along the same horizontal line and with centers $21\frac{1}{2}$ in. apart. These openings in the brick wall are protected from storms by an extension of the roof, which is about 2 ft. above the openings, and by a cement wall 2 in. thick and 2 ft. outside of the brick wall that drops from the extended roof of the front part of the building to the lower roof of the rear part.

In this cement partition or wall there is a row of circular holes opposite to the holes in the brick wall, but each hole in the cement wall is only 10 in. in diameter. After passing through these two sets of openings the nine wires of the three transmission circuits enter single-pole, double-blade knife switches that connect each wire with a bank of lightning arresters and with a 10,000-volt type H oil switch

FIG. 2.—DOCK STREET SUB-STATION, SCHENECTADY.

of General Electric make. From these oil switches two of the three circuits go through other knife switches to the two I. R. T. regulators; thence through still other knife switches to 15,000-volt, type K oil switches of General Electric make, and from these K switches to more single-pole, double-blade knife switches that connect with static discharges and underground cables. The third 10,800-volt circuit, after passing through an H oil switch with knife switches on each side, goes to the transformers that lower the pressure to 2,300 volts for local distribution.

All three of the 10,800-volt circuits, after leaving the H oil switches, connect with duplicate sets of bus-bars by means of which any one of these circuits can be joined to either I. R. T. regulator, or to the transformers. The lightning arrester cells, the static dischargers

of the Albany company the distance is about two miles, and twelve standard clay ducts, each 4 in. in diameter, have been laid in Portland cement concrete between these two stations. For present purposes two three-phase cables have been laid in these conduits in order to deliver the 10,800-volt current at the Trinity Place station. Each of these cables contains three 3/0 stranded copper conductors, is insulated with paper, and covered with a lead sheath $\frac{1}{8}$ in. thick. At the station of the Albany company a new fire-proof addition has been built to receive the 10,800-volt underground cables and contain the high-tension switching and transforming apparatus. This addition adjoins the brick wall that forms one side of the main steam power station, has brick walls one story high, measures 32 ft. 4 in. by 37 ft. 4 in. outside, and has a concrete floor and a concrete cemented roof, this latter being supported on steel I-beams. A 15-ton traveling crane sweeps the entire space included within the addition save what is devoted to the switching apparatus and bus-bar compartments.

On the distribution system of the Albany company the load consists of open direct current and of enclosed alternating arc lamps, incandescent lamps on two-phase circuits, and of direct-current motors. The entire load has previously been carried by steam power at the Trinity Place station, and the plan in the application of transmitted water power in the system was to abandon the regular use of steam and yet make no changes in the character of the connected loads. To avoid any such change it was necessary to continue the operation of the 9.6-amp., direct-current arc dynamos and of two-phase, 60-cycle alternators, also to substitute rotary converters for the abandoned direct-current, 500-volt generators that had been used to carry the motor load.

On entering the new addition of the Trinity Place station the two underground cables connect with oil switches and high-tension bus-bars of Westinghouse make. From these switches and bus-bars connection is made with four banks of transformers all located in the fire-proof addition to the old station. Each of two of these groups of transformers consists of three units rated at 200 kw, making 600 for the group. These three transformers reduce the 10,800-volt, three-phase current to 375 volts for a 500-kw, 550-volt rotary converter that is located in the main station. There are thus two of these converters with a combined capacity of 1,000 kw for the load of direct-current motors. Each of the other two groups of transformers consists of two units rated at 400 kw each and connected Scott fashion so as to change the current from three-phase to two-phase, while reducing its pressure from 10,800 to 2,300 volts. This 2,300-

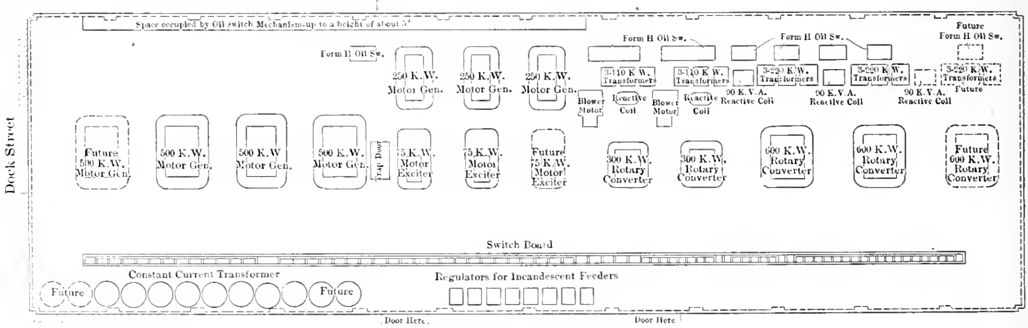

FIG. 3.—PLAN OF DOCK STREET SUB-STATION.

and both the types of oil switches are all located in the front end of the sub-station on two floors, and are separated from the remainder of the sub-station by the brick wall already mentioned. The conductors between these several switches and bus-bars are bare copper, and like the knife switches are supported at the tops of large porcelain insulators like those used outside on the line. Each of these insulators is mounted on a wooden pin that is 9 in. long above the shoulder, and that is cemented into the brick wall of the building. The clips of each knife switch are attached to a cast-iron cap that is cemented to the top of one of the insulators just named. This method of insulation is highly effective.

After leaving the K oil switches the 10,800-volt circuits connect with underground cables that run to the station of the Albany Electric Illuminating Company on Trinity Place. From the above sub-station of the Hudson River Water Power Company to the station

volt current passes to the switchboard for distribution lines in the main part of the station, which is separated from the transformers by a brick wall. With the 2,300-volt, 40-cycle current thus obtained the distribution circuits for incandescent lamps and induction motors are supplied.

The old station contains a long main shaft to which the arc dynamos and 60-cycle, 2,300-volt alternators have been connected by belts in the past, the shaft itself being driven by steam power. The steam engines have been uncoupled from this shaft, though the connection can be quickly remade if it becomes desirable, but the arc dynamos and one 225-kw alternator remain belted to it. Near each end of this line of shafting and directly coupled therewith are synchronous motors, each rated at 550 kw, 10,800 volts and 343 r.p.m. These motors draw their current from the high-tension switches and bus-bars in the new addition to the station, and the same is true of a third motor of like voltage and capacity that is direct-connected to a 225-kw alternator at each end of its shaft. This third motor and the two alternators to which it is coupled operate at 480 r.p.m., and the alternators develop two-phase, 2,300-volt, 60-cycle current. These alternators are devoted to the circuits that operate commercial, enclosed arc lamps. The transformers, rotary converters and synchronous motors just mentioned were all furnished by the Stanley Company.

Public street lighting in Albany is done entirely with open arc, direct-current, 9.6-amp. Brush lamps, and about 680 of these lamps are in use and connected to the station of the Albany Electric Illuminating Company. To the circuits of the company there are also connected direct-current motors of about 1,500 hp total capacity at 550 volts and arc and incandescent lamps of about 2,000 kw combined capacity on 2,300-volt, two-phase lines.

In order to reach the electric lighting station in Troy from the Watervliet sub-station of the Hudson River Water Power Company it is necessary that the 10,800-volt lines cross the Hudson River. A point about one mile down stream from the sub-station and nearly opposite to the lighting station in Troy was selected for this crossing, and a cable was laid in the bed of the river. Bare overhead conductors run from the Watervliet sub-station to the cable landing on the west bank of the Hudson, and there enter a small brick terminal house where they join the cables and have lightning arresters attached.

After crossing the river the cables enter a large manhole close to its east bank and are there connected to underground cables that run to the lighting station, a few hundred feet away. Two cables were used to cross the river, which was covered with a thick coating of ice at the time they were laid, in December, 1903. By means of horses the two heavy cables were dragged across the river on the ice so that they lay side by side over the location on its bed, where they were to rest, which had been previously determined, and then the ice was sawed through on each side of the cables so that they sank into position by their own weight.

Each of these two cables contains three No. 3/0 stranded copper conductors, is insulated with paper, enclosed within a lead sheath, and protected on the outside by a layer of galvanized steel wires that are laid in spiral form on a bed of jute that rests on the lead sheath. Between the 3/0 wires the thickness of paper is ½ to 9/16 in. and between each wire and the lead sheath the paper measures about ⅜ in. This insulation was tested with 25,000 and 50,000 volts applied for one hour. The lead sheath outside of the paper has a radial thickness of 3/16 in., and then comes the layer of jute or other fibrous material, which is 1/16 in. thick, and supports the armor of No. 4 Birmingham gauge steel wires. Outside of this armor the cable has a diameter of 3⅜ in. Both of the cables were made by the National Conduit & Cable Company.

At Troy the connected load on the electrical supply system includes about 15,000 incandescent lamps of nominal 16-cp rating, 290 enclosed arc lamps in commercial use, 427 direct-current, open-arc lamps for street lighting that are rated at 2,000 cp each, 40 open arcs for stores, and 125-kw capacity in direct-current motors. Dynamos for the operation of these several loads have been previously driven by steam power through a long main shaft at the Troy lighting station. In the application of the transmitted water power to these loads the steam engines were disconnected from the main shaft, and synchronous motors were installed to drive it and the several types of dynamos. These dynamos include direct-current arc machines of 9.6 amp., 2,300-volt alternators, and 500-volt, direct-current generators for the motor load. The underground cables bringing the 10,800-volt, three-phase current from the Watervliet sub-station enter the old lighting station at Troy, and this current, after passing through oil switches, goes to the 10,800-volt synchronous motors without transformation. In this way the old generating equipment at Troy is retained, and is driven by synchronous motors and water power instead of by steam engines.

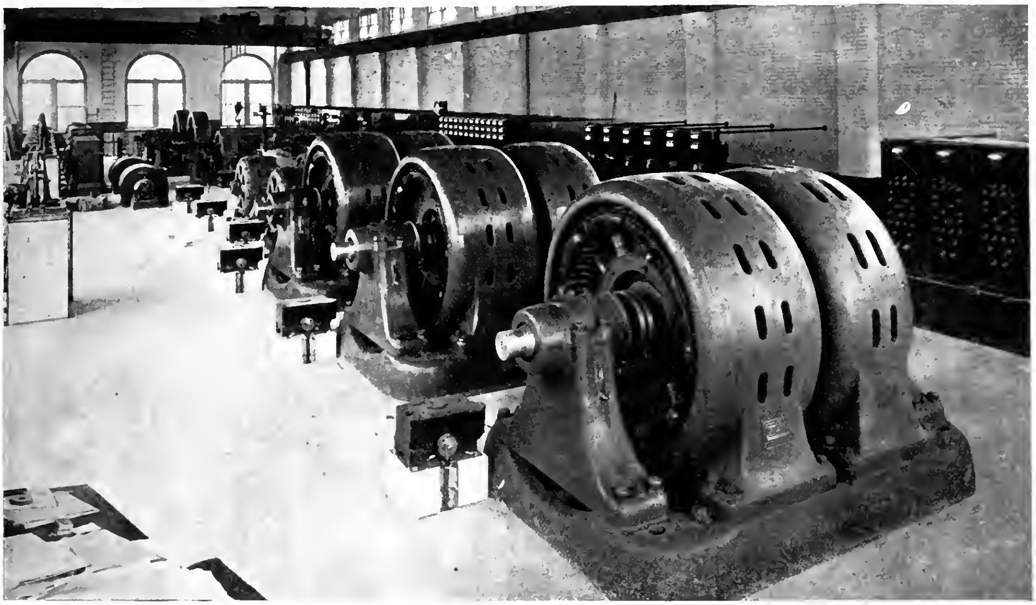

FIG. 4.—ANOTHER VIEW OF INTERIOR OF DOCK STREET SUB-STATION, SCHENECTADY.

Besides the supply of transmitted energy to the local lighting systems of Albany and Troy, as above outlined, the Hudson River Water Power Company also furnish a large part of the power used to operate the electric car lines of the United Traction Company in and between these two cities. Power for this electric railway system is delivered in the form of 10,800-volt, three-phase, 40-cycle current at two sub-stations of the United Traction Company, one located near the Watervliet sub-station of the Hudson River Water Power Company, and the other at North Albany some four miles away. At each of these railway sub-stations the 10,800-volt current from the water power plants is transformed to about 375 volts and delivered to rotary converters that supply direct current at about 550 volts. The contracts between the Hudson River Water Power Company and the Albany lighting company, the Troy lighting company and the United Traction Company look to the complete substitution of transmitted water power for steam in the entire public lighting and street railway systems in these two cities as soon as sufficient generator capacity has been installed in the great plant at Spier Falls to meet the maximum requirements at these and other points, when operated in conjunction with the water power station at Mechanicville.

The transfer of electric lighting and railway loads in Albany and

Troy to the water power system completes the substitution of energy drawn from the Hudson River for steam power in electric systems over a territory some 15 miles wide east and west, and 45 miles long north and south. This territory includes Glens Falls on the north, Troy on the east, Albany on the south and Schenectady, Ballston and Saratoga on the west. Probably no other single electric system in the United States serves an equal population over an equal area with an equal amount of power.

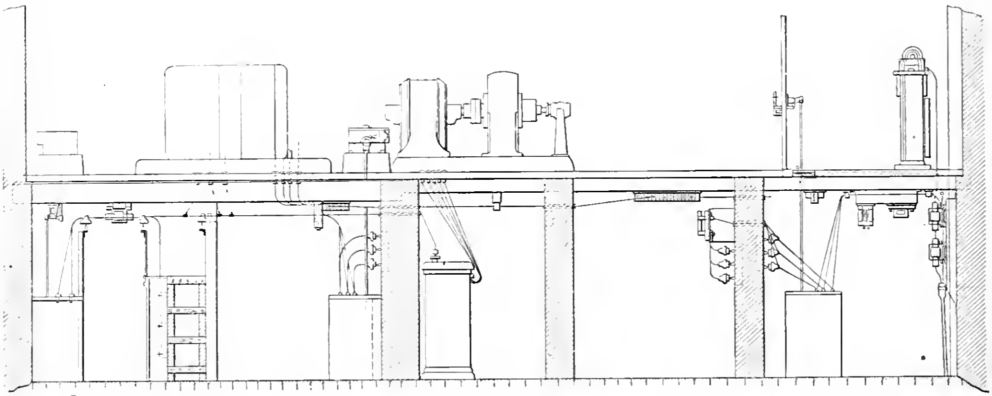
Transmitted water power from Spier Falls and Mechanicville also operates the electric railway and lighting systems of Schenectady, N. Y. Both of these systems are owned by the Schenectady Railway Company, and the energy for their operation is delivered through the main switchboard in the power station at the General Electric Works. Energy from steam as well as from water power is available at the General Electric switchboard, so that certainty of continuous service on the railway and lighting systems is secured without auxiliary steam equipments in its sub-stations.

As at present operated, the railway and lighting systems have three sub-stations, one on Dock Street close to the General Electric Works in Schenectady, one at Colone on the branch of the railway that connects Schenectady and Albany, and one at Latham's Corner on the railway between Schenectady and Troy. The Dock Street sub-station distributes light and power in Schenectady, besides delivering current to the railway, but the other two sub-stations carry only railway loads. When the branch of the Schenectady railway that connects that city with Ballston Spa is in operation a fourth sub-station located at the latter place will supply power to that branch.

Between the power station at the General Electric Works and the new sub-station on Dock Street there are three underground cables each containing three 3/0 stranded copper conductors. Each of these cables carries 10,000-volt, 40-cycle, three-phase current drawn from step-down transformers in the General Electric plant, and the current delivered by two of the cables is devoted to railway work, while the third supplies energy to the lighting system. From the Dock Street sub-station to that at Colone there are two circuits of three No. 1 B. & S. gauge wires each, and between the Colone and the Latham's Corner sub-stations there is one circuit of three No. 2 B. & S. gauge wires. Between the Dock Street sub-station and the city limits of Schenectady the two circuits of No. 1 wire are made up of two paper-insulated lead-covered underground cables, with three conductors each, but the remainder of these circuits, and that of No. 2 wire are bare overhead conductors. These circuits running to the Colone and Latham's Corner sub-stations transmit the 10,000-volt, three-phase current delivered to the Dock Street sub-station from the General Electric Works.

When the sub-station at Ballston Spa is in operation its energy will be drawn directly from one of the two transmission circuits between Spier Falls and Schenectady, before they reach the General Electric Works. At the sub-station just named the electric railway equipment will include two 300-kw, 550-volt, 40-cycle rotary converters to operate at 800 r.p.m. three 220-kw air-blast transformers with double secondary windings, and two 45-kw air-blast reactive coils, all made by the General Electric Company. A 2-hp, three-phase induction motor will drive a direct-connected, 35-in. blower, and a 20-hp motor of the same type will operate a Magan air compressor. At the Colone and also at the Latham's Corner sub-station, both of which have been in regular operation for some time, there are three 300-kw rotary converters supplied with energy from the 10,000-volt line through transformers and delivering direct current of about 550 volts.

The new sub-station on Dock Street has recently been put into service to replace an old power house and sub-station nearby and carries all of the lighting and stationary motor service at Schenectady as well as a large share of the street railway load. The ground area of the sub-station is 165 ft. 8 in. by 45 ft. 2 in., and its elevation includes a high basement and main operating room or first floor above. The basement floor of this sub-station is slightly above the ground level outside because the Hudson River and Erie Canal near which it is located are liable to overflow. From ground to coping the height of the sub-station is 40 ft. 4 in., from basement floor to main floor the distance is 10 ft., and main floor to the lower cord of the steel roof trusses the distance is 24 ft. In structure the sub-station is of



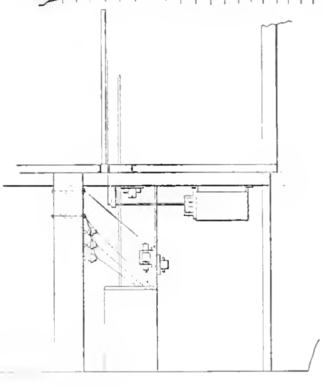


Fig. 5.—Cross-Section of Lighting End Dock Street Sub-Station, Showing Wiring.

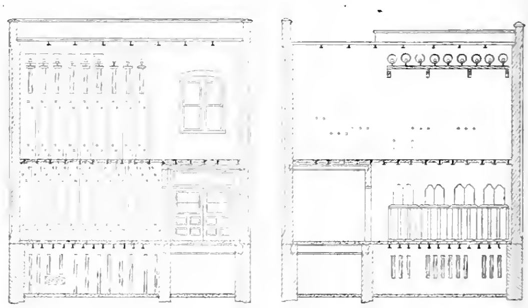

Fig. 6.—Cross-Sectional Elevations of Cell Rooms.

stone, brick, concrete and steel, save for the three-inch plank that supports the slag covering of the roof.

Up to the level of the main floor the outer walls are of brown stone, and above this they are brick. In thickness the stone wall is 20 in., increasing to 27½ in. at buttresses, and the brick wall above is 12 in. thick, increasing to 24 in. at buttresses. The basement floor is formed by a one-inch layer of cement on 4 in. of concrete, and the main floor is composed of concrete arches resting on steel I-beams and all supported by the outer and by interior walls. The sub-station is lighted by large windows along three sides and smaller, high windows on the fourth and along the center line of the roof are ranged four 36-in. globe ventilators.

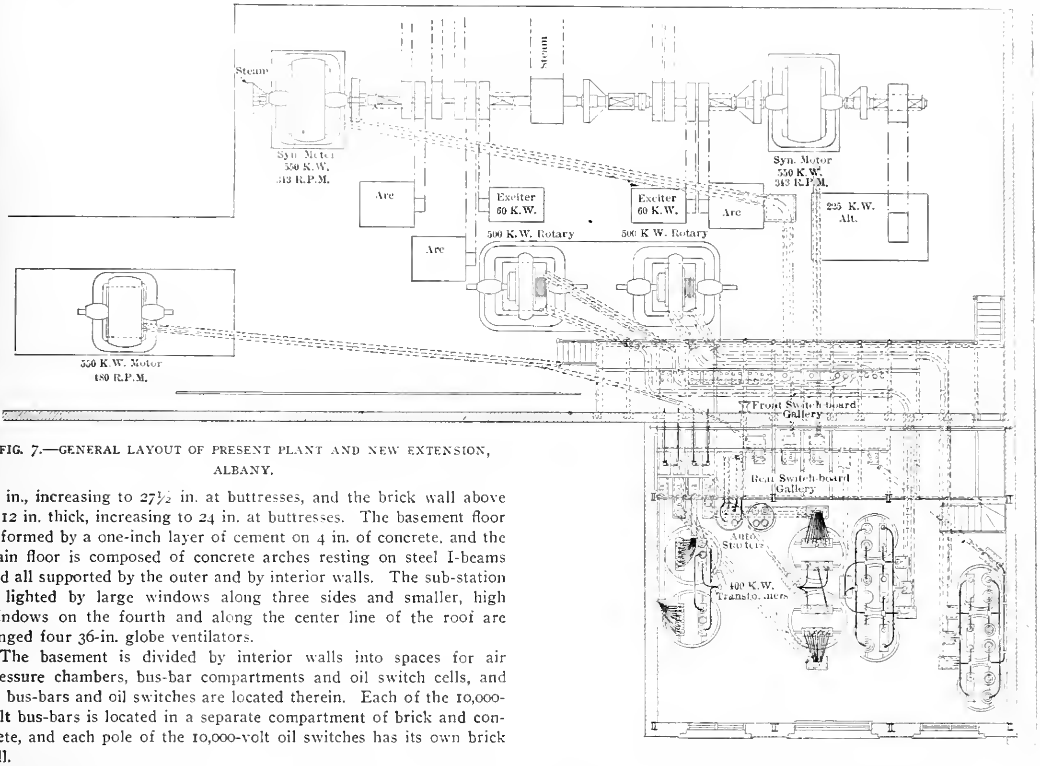

FIG. 7.—GENERAL LAYOUT OF PRESENT PLANT AND NEW EXTENSION, ALBANY.

The basement is divided by interior walls into spaces for air pressure chambers, bus-bar compartments and oil switch cells, and all bus-bars and oil switches are located therein. Each of the 10,000-volt bus-bars is located in a separate compartment of brick and concrete, and each pole of the 10,000-volt oil switches has its own brick cell.

The entire main floor of the sub-station is swept by a 15-ton traveling crane, and this crane runs over an archway at one end of the building, where teams can drive in at the basement level. The 18-in. I-beams on the side walls of the sub-station on which the crane travels are supported by the brick abutments, and these abutments are not reinforced by steel columns. On the main floor of the sub-station are located transformers, the operating gear of oil switches, rotary converters, exciters, synchronous motor-generators and the switchboard panels. Along one-half of the main floor the railway apparatus and along the other half the lighting apparatus is located. Current is supplied to this apparatus in part by six transformers, each rated at 10,000 to 375 volts, and 110 kw, and of the air-blast type. These six transformers are connected in two groups with two rotary converters, each rated at 300 kw, 40 cycles and 600 volts. Two other banks of transformers are made up of six units with a rating of 10,000 to 375 volts and 220 kw each, and each of these banks feeds a 600-kw, 600-volt, six-phase, 40-cycle rotary converter. With each of the 300-kw rotary converters there is a 45-kilovolt-amp. reactive coil of the air-blast type, and with each 600-kw rotary there is a 90-kilovolt-amp. reactive coil of the same type. Space has also been provided for three more 220-kw transformers and one 600-kw rotary converter with its reactive coil. Each group of three transformers

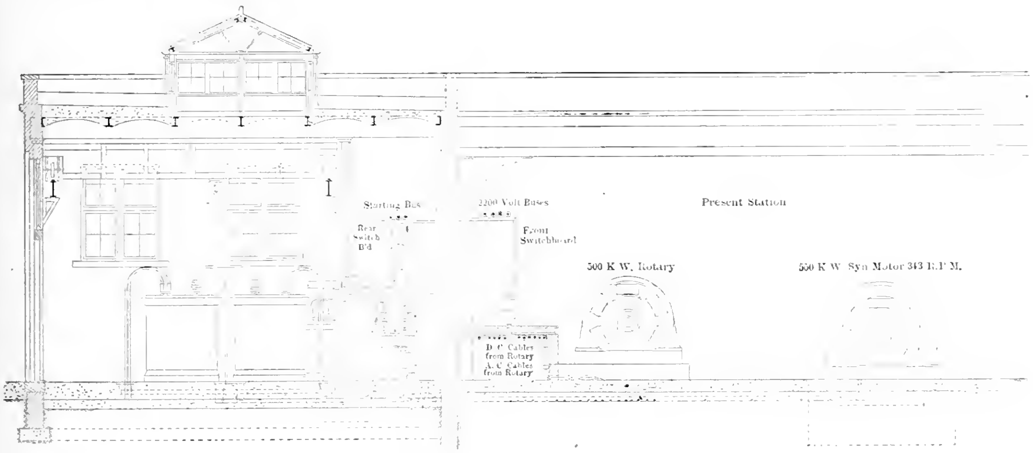

FIG. 8.—CROSS-SECTION THROUGH PRESENT STATION AND NEW EXTENSION, ALBANY.

is connected to the 10,000 bus-bars through a type H General Electric oil switch, electrically operated by current from a battery of 55 type E storage cells made by the Electric Storage Battery Company. The panels that carry the controlling switches for all the apparatus at the sub-station are of black enameled slate, and the maximum pressure to which they are exposed is 15 volts. Of these panels three carry instruments for three incoming lines of 10,000 volts and 4,000-kw capacity each. On each of these three panels there is one horizontal edgewise ammeter, one voltmeter of the same type, one double-pole

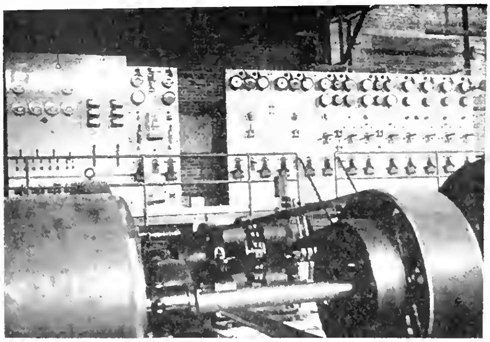

FIG. 9.—SWITCHBOARD, ALBANY.

overload relay that indicates by lamps whether the oil switches are open or closed, one controlling switch for the type H oil switch, and a current and potential transformer and static dischargers. The two panels for outgoing lines are of 10,000 volts and 1,500-kw capacity each, and equipped like the incoming panels with the addition of polyphase induction recording wattmeters. For each rotary converter the panel includes a recording wattmeter, power factor indicator and overload relay, besides volt and amperemeters, controlling

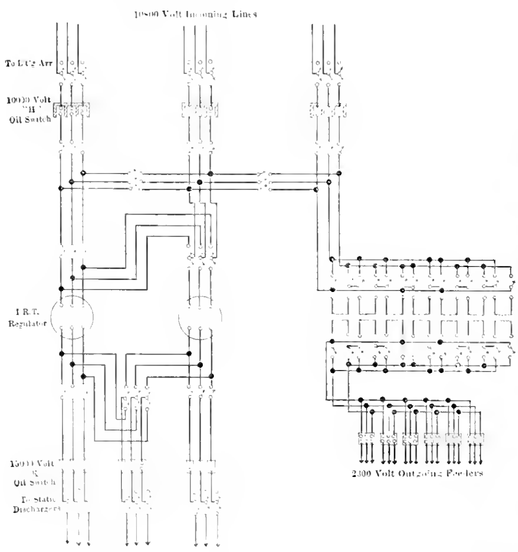

FIG. 10.—DIAGRAM OF MAIN CONNECTIONS, ALBANY SUB-STATION.

switches for the type H oil switch, indicating lamps and secondary transformers. Lamps in the sub-station may be operated from either the regular lighting circuits, the railway circuit or from the storage battery above mentioned.

Two 75-kw motor-driven exciters are already in use at the sub-station, and space has been provided for a third set when required. The lighting equipment at this sub-station includes synchronous motor-generators and constant-current transformers. Each of three of the motor generators is made up of a 550-kw, 10,000-volt, 40-cycle, three-phase motor, and a 500-kw, 2,300-volt, 60-cycle, three-phase generator. Space for a fourth motor generator of this capacity is also provided. Each of the other three motor-generators is of 250-kw output capacity, and converts the 10,000-volt, 40-cycle, three-phase current to 2,300 volts and 60 cycles. Each synchronous motor of these motor-generators is connected with the 10,000-volt, three-phase bus-bars through one of the electrically-operated type H oil switches. Series arc lighting is provided for by eight constant-current transformers of 4,000 volts and 6.6-amp. capacity each. These

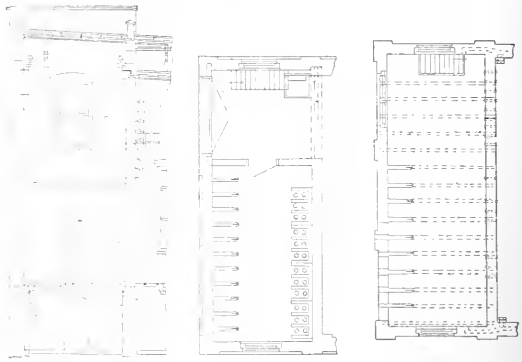

FIG. 11.—SECTION AND PLANS, ALBANY SUB-STATION.

transformers are supplied with 2,300-volt, 60-cycle current from the motor-generators. Current of 40 cycles was tried for arc lighting from the old sub-station, but its use has been abandoned. As may be seen from this list of equipment, the sub-station sends out only two sorts of current for the general supply of light and power; that is, current of 60 cycles at 2,300 volts and constant-current of 6.6 amp. and the same number of cycles as the other. Two automatic regulators are provided at the sub-station for the two most important 2,300-volt circuits that leave it for lighting service, and hand regulators are connected in the other 2,300-volt lighting feeders.

Between the Dock Street sub-station and the main business parts of Schenectady the lighting and power circuits are composed of underground cables in Camp tile ducts. Feeder cables for the 2,300-volt circuits have three conductors each, and these conductors in

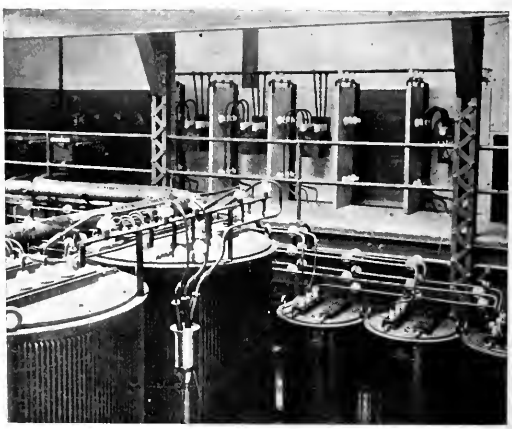

FIG. 12.—TRANSFORMERS, ALBANY.

most cases are each of 500,000 cm. cross-section. For the constant-current arc circuits single-conductor cables are used. The general distribution system for light and power at constant pressure includes 2,300-volt, 60-cycle, single-phase primary mains, subway transformers in manholes and three-wire secondary mains at about 250 volts. In the outlying parts of the city the 2,300-volt underground feeder cables connect with overhead feeders, and these feeders supply banked transformers and secondary three-wire mains as far as is practicable. Separate transformers for single customers are used only in isolated locations. The connected load of the Schenectady electrical supply system includes constant, alternating-current arc lamps, constant-pressure alternating arc lamps, incandescent lamps on constant-pressure circuits, and induction motors at 550 or lower voltages. All arc lamps are of the enclosed type. Substantially all of the commercial service is supplied through meters of which there are 5,306 in use with 5,309 customers. The number of arc lamps used for street lighting is 440 of the 6.6-amp. type on series circuits, with an estimated equivalent capacity of 4,400 incandescent lamps of 16 cp each. Commercial arc lamps on constant-pressure circuits number 519, with individual ratings of 4 to 25 amp., there being 10 of the largest size, and the number rated at 6 amp. each is 482. Estimated on the basis of 16-cp incandescent lamps, the equivalent capacity of these commercial arcs is 10,030 in number. Commercial incandescent lamps number 84,572, and their equivalent capacity in lamps of 16 cp is 79,-

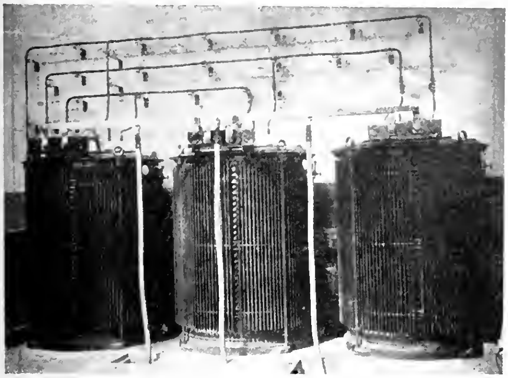

FIG. 13.—A GROUP OF TRANSFORMERS, ALBANY.

180. In candle-power these incandescent lamps range from 4 to 100, and the number of 10-cp lamps is 16,820, of 16-cp 63,769, and of 100-cp 6.

All motors are of the induction type, and their total number is 173, with a combined rating of 671 hp, and an equivalent capacity of 11,140 incandescent lamps of 16 cp each. These motors range from 1/16 to 50-hp capacity, and there are five of the 20-hp, five of the 30-hp, and two of the 50-hp size. The equivalent rating of all the lamps and motors above named is 100,350 incandescent lamps of 16 candle-power.

Besides the above connected load the Schenectady Railway Company has secured a twenty-year contract, subject to confirmation at the end of each three-year period, to pump all of the public water supply for the city. This water is pumped into standpipes under a head of 110 pounds and with a suction of 6 pounds. For the work of pumping there have been provided two vertical turbine centrifugal pumps with a daily capacity of 12,000,000 gallons. To each of these pumps there is direct-connected an 800-hp, 40-cycle, 550-volt induction motor. Each motor is supplied with current from the 2,300-volt, 40-cycle, three-phase line through three transformers rated at 250 kw each. Two pole lines and circuits extend from the Dock Street sub-station to the pumping station, and the supply of power is assured by the fact that not only the water-driven stations at Spier Falls and Mechanicville, but also the steam plants at the General Electric Works can be drawn on. The entire electrical equipment at the Dock Street sub-station, and most of the lamps and motors on the supply system are of General Electric make. The facts as to this notable application of water power have been obtained through the kindness of Mr. A. L. Rohrer, of the General Electric Company, and Mr. F. G. Sykes, of the Schenectady Railway Company. The Schenectady system is shown in Figs. 1 to 6. The Albany system is illustrated in Figs. 7 to 13.

New Rapid Transit Tunnel for New York.

Governor Odell has signed the two New York City rapid transit bills passed by the New York Legislature. The bills were introduced at the request of the Rapid Transit Commission, which is now enabled to proceed with the arrangements for the construction of another independent rapid transit tunnel up and down Manhattan Island.

Lamme Single-Phase Railway System.

Two patents were issued May 3 to Mr. Benjamin G. Lamme on applications filed December 26, 1901, covering his single-phase alternating-current electric railway system, one being a so-called "system" and the other a "method" patent. The specifications cover in an abridged form the specifications of the English patent, which were printed in full in our issue of February 13 of this year. As against the four claims in the English patent, the American "system" patent contains seventeen claims and the American "method" patent eight claims. The illustrations are the same as those in the English patent, with one exception in the "system" patent, which illustrates a method of voltage regulation.

Referring to Fig. 1, the car transformer has two secondary circuits, one of which is closed on itself and the active length made variable by means of a switching device. The variable voltage in this circuit may be impressed upon the motor circuit through the series transformer diagrammatically indicated. By reversing the connections this variable impressed voltage may be employed either to subtract from or add to the voltage of the motor circuit through all of its varying values, thereby providing the necessary variation of

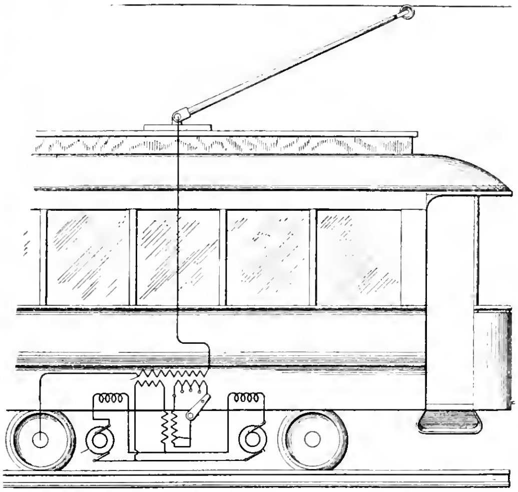

FIG. 1.—DIAGRAM OF CAR TRANSFORMER.

motor speed from zero to the desired maximum. It is stated that with this combined arrangement the motors may be designed for such voltage and such current as are best adapted for their operation, and the controller designed for some other voltage and current best adapted for its operation. Instead of varying the active length of a portion of the main transformer winding, the magnetic relations of the primaries and secondaries may be varied by adjusting one of the parts with reference to the other in a well-known manner; or such adjustment may be combined with means for varying the active length of a portion of a transformer winding.

A third patent issued on the same date to Mr. Lamme, on an application filed October 31, 1902, relates to details of his single-phase alternating-current motor. The object of the invention is stated in the patent to be to provide a single-phase motor with high-resistance conductors between the armature coils and the commutator bars, which shall be advantageously disposed with reference to the other parts of the motor.

In motors of this type the armature winding is of the closed-coil, parallel-circuit type and is closed upon itself, and as the magnetic field of the motor is alternating, any short-circuited turn through which the magnetic flux from a field pole passes will have a secondary current set up in it. By the well-known laws of the transformer, the ampere-turns in such short-circuited secondary will approximate the ampere-turns in the primary winding, which is in this case the field magnet winding. By reason of the character of the armature winding certain of its coils are short-circuited through the brushes when the adjacent commutator bars, to which the ends of the coils are connected, are bridged thereby, and when the brushes are located in neutral positions or without lead the short-circuited turns surround the paths of the magnetic flux and are, therefore, good secondary circuits in which under ordinary conditions relatively large secondary currents are set up by induction. This is the principal cause of the excessive sparking in series motors of ordinary construction when it is attempted to operate them upon an alternating-current circuit.

In order to obviate destructive sparking, the current in the short-circuited turns of the armature coils should be limited to an amount materially less than what would normally flow. This may be effected by inserting a definite amount of resistance in each of the leads between the closed winding and the commutator bars. The working currents in the armature winding will not pass through these resistances except at the bars in contact with the brushes, because the armature winding is closed upon itself inside or beyond the resistance leads. Consequently, the loss in the winding due to the introduction of the resistance may be relatively small, and when the armature is rotating this loss is distributed successively through all the resistances, thus making the average loss per resistance lead very small. Various ways of introducing such a resistance may be employed; but to provide the desired amount of resistance and at the same time so dispose it that it will be securely supported under the comparatively rapid rotation of the armature is a somewhat difficult problem.

In motors of large power employed for operating railway vehicles the space allowable for the motors is extremely restricted, and hence it is a matter of material importance to so dispose the several elements of the motor as to secure the desired ventilation and general efficiency without occupying more than the allowable amount

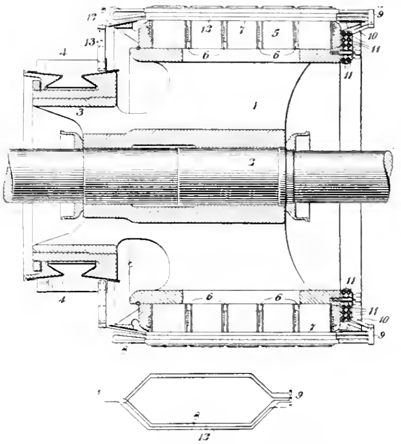

FIG. 2.—SECTION OF ARMATURE AND COMMUTATOR.

of space. Fig. 2 shows a longitudinal section through an armature and commutator of such a section, and a diagram of one of the armature coils.

The skeleton frame or spider, 1, of the armature is mounted upon and keyed to the shaft, 2, in the usual manner and is provided with an extension, 3, on which is mounted the commutator, 4. The laminated core, 5, is mounted and suitably fastened upon the frame or spider, 1, and is provided with ventilating ducts, 6, and with slots, 7, in which are mounted the coils, 8, these coils being connected at the end remote from the commutator by means of suitable connectors, 9, so as to form a closed parallel circuit winding, the winding being also joined by means of conductors, 10, to balancing rings, 11, in order to properly balance the magnetic circuit.

Each coil, 8, is connected to its appropriate commutator bar by means of a conductor, 12, of relatively high resistance and a connector, 13, one end of which is fastened to the corresponding commutator bar and the other end of which is fastened to the corresponding end of the resistance conductor, 12. This conductor, 12, may be formed of German silver or other suitable high-resistance material and is located in the bottom of the slot, 7, it being provided with a suitable insulating sheath in the same manner as are the corresponding portions of the coils, 8. There is, obviously, one of these resistance conductors, 12, in each slot, and since it is located in the bottom of the slot it is advantageously disposed both as regards the security of its position and also because it does not interfere in any way with the proper disposition of the other parts of the machine.

The claims cover the combination with a commutator of an armature core provided with slots, a parallel closed circuit winding and high-resistance leads connecting the winding with the commutator bars, the coils and leads being located in the slots and connected together at the end of the armature remote from the commutator.

On the same date a patent was issued to Mr. Charles F. Scott on a system of alternating-current distribution particularly adapted to

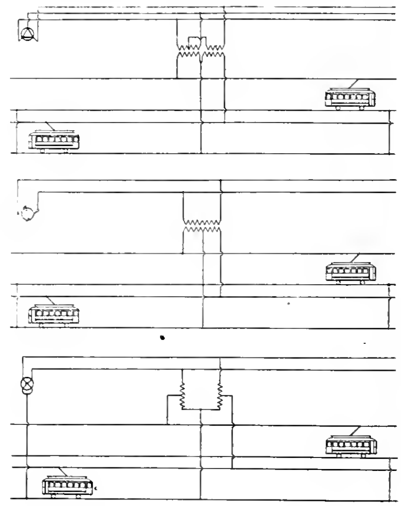

FIG. 3.—DIAGRAMS OF DISTRIBUTION SYSTEMS.

systems employed for operating single-phase alternating-current motors, the armature and field magnets of which are in series relation. The object of the invention is stated to be to provide a system of distribution and transformation which shall insure economy in the use of electrical energy by the use of a single-phase transmission system for the operation of electric vehicles upon two parallel tracks. In the accompanying illustration, Fig. 3, the upper diagram refers to a three-phase transmission circuit, a double-track railway and transformers for supplying single-phase currents to the motors on their respective tracks. The middle portion is a corresponding diagram of a single-phase transmission system, and the lower diagram that of a two-phase, three-wire transmission system.

In the first-mentioned method three-phase currents are transformed to two-phase currents, one side of the two-phase circuit being connected with the track. It is stated that by this arrangement a saving in conductors for the transmission circuit is effected by employing the three-phase system, and that a further saving is effected by using the rails of the two roads as a common return for both circuits. In the single-phase arrangement the line voltage is transmitted at double the voltage of the trolley circuit, the rails being connected to the middle point of the secondary of the line transformer. The third method relates to a two-phase system employed with a ground return. It is stated that with this system there are the advantages of a polyphase transmission system and a saving in conductors by the use of the rails as return circuits for both phases of the high-voltage circuits and also for the two trolley circuits.

Western Union and Erie.

It was reported last week that the Postal Telegraph-Cable Company would displace the Western Union Telegraph Company's service along the line of the Erie Railroad. It was also reported that a like change would take place about July 1 on the Pennsylvania lines west of Pittsburg. As to the former report both President Underwood, of the Erie, and President Clowry, of the Western Union, deny any knowledge whatever.

Recent Electrochemical Developments.

ELECTROLYTIC PROCESSES.

The consumption of tin has increased enormously in recent years, notably on account of the very large amounts of tin used for tinned iron for canning. The production of tin from the ores has also increased, but not to the same degree. Under these circumstances, the electrolytic winning of tin from tinned iron scraps or from the cans after the preserves have been eaten has become a well-paying business. It is estimated that in Germany alone at present about 35,000 tons of tin scraps are treated per year electrolytically, from which 2 to 2.5 per cent., i. e., about 800 tons of tin are won, amounting to about $500,000. These processes are used on a large scale, notably in two German plants, but have been introduced later into Holland, and also recently to this country. The processes used are kept secret, especially the electrolyte, although it is generally understood that the commercially successful companies use an alkaline electrolyte.

A patent granted on April 26 to Mr. E. Quintaine, of Argenteuil, France, relates to a new process of this kind, the feature of which is the electrolyte which consists of a solution of acid nitrate of tin, to which a certain quantity of sulphate of ammonia is added in order to neutralize the bath. The inventor prepares a bath of a solution of acid nitrate of tin, to which is added gradually a certain amount of sulphate of ammonia and a tin chloride. This gradual addition to the solution is continued until precipitation ceases.

A patent granted on May 8 to Mr. H. Spence, of Manchester, England, refers to the production of a "new titanous sodium-sulphate compound" for use as a reducing agent in various manufacturing processes, in the discharge of coloring matters from textile fabrics, etc. The compound is produced by means of electrolytic reduction of titanium sulphate in the presence of sulphuric acid, with an addition of sodium-sulphate, and by means of evaporating the solution afterwards.

The importance of thorough stirring of the electrolyte for certain electrolytic processes is well known. Some means of stirring becomes necessary whenever the object to be obtained by electrolysis requires the solution to be kept as much as possible in its original condition. For instance, if a metal is to be deposited from a solution of one of its salts, the tendency of electrolysis is to render the solution near the cathode poor in the ions of the metal to be deposited. This results then in a new reaction which is mostly generation of hydrogen, and represents a waste of energy. Various apparatus have been suggested by which it is possible to obtain a thorough agitation of the electrolyte. Two patents granted on April 26 to Mr. G. E. Dunton, of New York City, refer to mechanical details of such devices. The author makes use of pumps and pipes provided with nozzles.

A patent granted on April 26 to Mr. G. K. Jenney. of New York City, refers to mechanical details of an apparatus for electroplating sound records. The inventor describes a case or holder by which the sound record discs may be supported through peripheral contact only and the record surface thereby fully exposed to the electrolytic action and protected at the same time from accidental blows or mutilation.

ELECTRIC DISCHARGES THROUGH AIR.

A further contribution to this subject which has been investigated by various experimenters in recent years—mainly with two objects in view, viz.: the fixation of nitrogen and the production of ozone—is given in two patents granted to Mr. J. N. Alsop, of Owensboro, Ky., on May 3. He does not state exactly the chemical compound which he wants to get, but says that the air after treatment contains nitrogen peroxide and traces of ozone and "is in a state of ionization." He states, however, explicitly for which purpose he wants to use his modified air. The object is to whiten and purify cereals and otherwise improve their quality. For instance, flour is very noticeably bleached, the dough then formed is drier and more elastic and sections of the loaves of bread made from such dough have a fine white color.

In his apparatus he uses essentially two sets of electrodes which in turn are separated to form an arc. When the arc between the first set of electrodes is formed by separating these electrodes, the electrodes of the second set are being brought together and when they make contact a short-circuit is produced and the arc of the first set is extinguished. The second set is then separated, etc.

STORAGE BATTERY INVENTION.

The well-known process of Mr. A. G. Betts for electrolytic lead refining has led the same inventor to a storage battery of the following construction described in two patents, granted on May 3. He places two graphite electrodes in a strong solution of lead fluosilicate containing some free acid or a somewhat acid solution of fluosilicates of lead, and another metal, such as copper, capable of being deposited by electrolysis practically free from lead from such a solution. On passing an electric current of moderate strength through the cell, peroxide of lead is deposited on the anode in a dense, adherent and well conducting form, while metallic lead or the other metal (copper) is deposited on the cathode. Free fluosilicic acid remains in solution. This represents the charging of the cell. During discharge the reactions are reversed.

A patent granted on May 3 to Mr. J. T. Niblett, of Greenwich, England, refers to the type of battery in which the cell is filled with granules or pellets forming the active elements. As active material the inventor uses a mixture of granulated lead or granules of lead oxide incorporated with kieselguhr.

A patent granted to Mr. V. G. Apfel, of Dayton, Ohio, refers to the following construction of a storage battery. The whole case is divided into two compartments, the inside surface of each compartment being electrochemically active. Each compartment contains a series of liquid-tight conducting cases, one within the other and insulated one from the other. Their respective interior and exterior surfaces are electrochemically active. Within the inner case of each compartment a central element is provided which constitutes one electrode.

A patent granted to Mr. W. J. Redmond, of Cleveland, Ohio, refers to the construction of a storage battery plate in which the surface is provided with a great many hair-like projections for holding the active material.

New Telephone Patents.

NEW RECEIVERS.

A three-pole receiver is undoubtedly unusual, but such is one recently patented by Mr. E. H. Strauss, of Chicago. The design of this may be best understood by a reference to Fig. 1 wherein, in the upper part of the figure, is shown a section of it. As will be noted, a metal cup supporting both diaphragm and magnetic system, is clamped within the casing by the cap piece. The single oblong coil surrounds

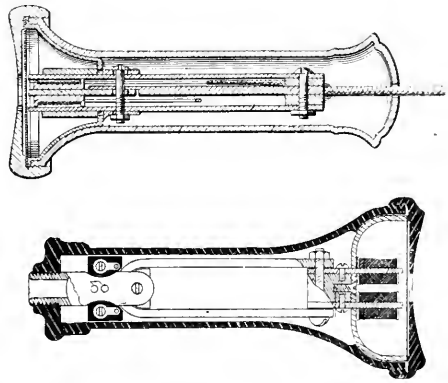

FIG. 1.—STRAUSS RECEIVER.

a flat rectangular pole piece, which is an extension of a central bar magnet. At the other extremity of this bar magnet are iron spacing pieces, outside of which are bolted two other bar magnets in such a manner that each forms a return pole piece extending nearly to the diaphragm. This magnetic system is adjustably supported from the metal cup, the clamping bolt securing it thereto running in slots in the base of the cup. A still further means of adjustment is obtained, by using this same clamping bolt to secure the pole piece to the central magnet and providing this pole piece with a slot. This enables an adjustment of the air-gap of the central leg of the magnet entirely independent of that of the side poles.

Still another receiver having the magnetic system supported from a metallic cup is that patented by J. S. Gemmill, of Cleveland, Ohio. A sectional view of this receiver is shown in the lower part of Fig. 1. The most novel feature is undoubtedly a clevis screwed into the tail of the receiver casing and spanning the closed end of the U magnet.

This serves to take up side strains and at the same time to form a guide for the receiver cords and a mounting for the hard rubber terminal block.

TRANSMITTER.

Mr. Gemmill has also patented a transmitter of a design to prevent moisture penetrating the granular button. This result is accomplished by supporting the front electrode upon a disc clamped between two annuli of sponge rubber. One of these is the insulating medium within the metallic granule box, and the front electrode supporting disc is held tightly against it. This pressure has, however, little effect upon the susceptibility of the electrode to motion, as it is caused by pressure exerted by an exactly similar ring, the net result being a supporting of the electrode between two balanced springs.

AN EXTENSION STATION WIRING.

Another circuit patent is that of Messrs. Charles E. Scribner and J. L. McQuarrie, of Chicago, which describes a method of so wiring a main and extension instrument upon a single line that these may be used independently of the central office and yet may receive their entire current supply therefrom. The circuit hinges upon the removal of the line relay from the ungrounded side of the line as usually arranged in the Bell Company's switchboards and the placing of it in the grounded side of the line. Thus, the battery may be fed

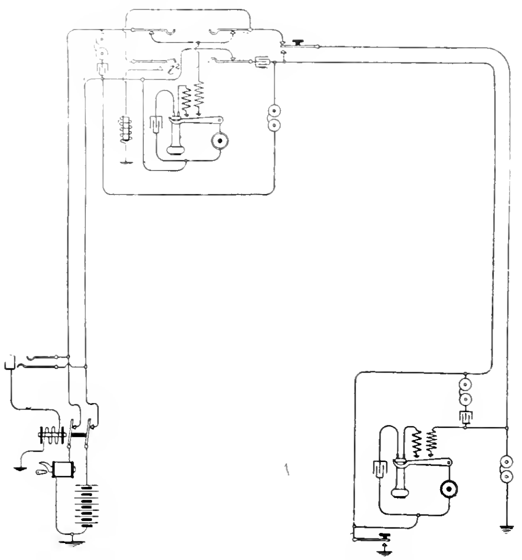

FIG. 2.—SCRIBNER & M'QUARRIE TELEPHONE SYSTEM.

out from the central office over one side of the line and return through the ground, without effecting the display of a line signal. Signalling between the main and extension stations is by single-stroke bells working by direct current under the control of contact keys located at the two stations. Provision is made that either station may call or be called by the central office; that either may call the other without signalling the central office; that that the main station may cut the extension from the circuit at will. With this explanation, the operation of the circuit, shown in Fig. 2, may be readily traced by those familiar with this line of work and to whom alone it is of interest. The Western Electric Company has obtained the patent by assignment.

TWO-WIRE SWITCHBOARD CIRCUIT.

A patent for a two-wire common battery switchboard circuit has just been issued to Mr. W. W. Dean, which differs considerably from the two-wire circuits now used by the Kellogg Company, to whom it has been assigned. In this system a line relay and a cut-off relay are provided, the cut-off relay leaving the talking lines undisturbed, and instead cutting off the line signal apparatus. In such an arrangement, but two wires being available, the cut-off relay must be included in series with the line relay, and to warrant its remaining unoperated during the display of the line signal, its resistance must be made low in comparison with that of the line signal. On the other hand, as during a conversation, the cut-off relay is virtually bridged across the line, a high resistance, therefore, is desirable. To meet both requirements, Mr. Dean has double-wound his relay, the windings being of unequal resistance and in series. The higher winding is normally shunted out by the back contacts of the relay. Now, when a calling signal is sent, the small line relay current passes without effect through the low-resistance cut-off relay coil. When the operator responds a large current traverses the cut-off relay until the relay can respond. Then the line relay being cut off, the shunt on the high resistance part of the cut-off relay is removed, and the relay now of high resistance remains in the operated condition until disconnection is made.

Copyright in Telephone List.

The Rocky Mountain Bell Telephone Company has issued a letter to the public of Salt Lake City asserting copyright in its telephone list. The notice is as follows:

Our attention has been called to a letter sent to our subscribers by the Utah Independent Telephone Company, signed by H. B. Brown, Manager Contract Department, offering to retain in the new company the same numbers now held in ours. For several years we have endeavored to convince the people of Salt Lake that two telephones would be a burden upon them, and that the Rocky Mountain Bell Telephone Company is able to give them all the service they need, and more than can be furnished by any other company for years to come. The letter referred to shows that the Independent Company expects you to subscribe to two telephones, with an added cost and inconvenience, which we claim is unnecessary. With our over 5,500 subscribers in Salt Lake, and our long lines connecting every city, town and village in the inter-mountain region, we feel justified in saying that we can give you a service that no other company can give.

This letter is called forth by a constant demand from our patrons to know what they should do. This is our answer: We have tried to serve you in the past and feel that we can do better in the future. Two telephones are a nuisance and will cost you more money than one; our advice is to wait and see whether the "pig in the poke" is worth buying. We most decidedly object to the use of our telephone numbers by the Utah Independent Telephone Company, or by any other company. Our telephone numbers are all copyrighted, and the property of this company, and will be protected.

CURRENT NEWS AND NOTES.

VOLUNTEER RUSSIAN TELEGRAPHERS.—The Czar of Russia has accepted the offer of the senior class of the Electro-Technical School at Odessa to serve as volunteer telegraphers in Manchuria. These volunteers will have charge of the wires along the Manchurian line.

INDEPENDENT TELEPHONES IN POST-OFFICES.—Some weeks ago the Postmaster-General ordered the removal from post-offices of all telephones that did not have long-distance connection with Washington. This cut out the independent service. The independent telephone interests protested against this action and sent representatives to Washington to secure a modification of the ruling. Their efforts, it seems, have been rewarded with success and a bill has passed through Congress providing for such an ample appropriation for telephone service that the independent companies will not be compelled to remove their instruments from post-offices. One of the principal claims for the independents has been that they have brought the people in touch with the public utilities.

THE EDISON MEDAL.—President Bion J. Arnold, of the American Institute of Electrical Engineers, has addressed to the educational institutions of the United States and Canada a statement with regard to the Edison Medal founded this year and calling their attention to the fact that it is open for competition by students for the best thesis or record of research on theoretical or applied electricity and magnetism. Mr. Arnold announces that the medal committee of the Institute is being formed and requests the authorities of institutions qualified and desirous to compete to send in their names to the medal committee, at 95 Liberty Street, New York City, on or before June 1, when further information will be given. It is hoped and expected that there will be a large competition from among the graduating students in electricity.

EVANESCENT RADIUM.—According to statements made by Prof. Sir William Ramsay, as reported in a recent special newspaper dispatch, there will be no more radium 1,150 years from now. It will all have disintegrated and vanished in the meantime. Radium, Sir Ramsay is reported to have said, instead of being a primeval substance which has been slowly disintegrating since the world began, is merely a temporary phase of matter, an unstable resting point in a series of transmutations, of which nobody knows the beginning, or end, or meaning. The rate of disintegration does not depend upon the quantity existent. It would all vanish, whether it measured a cubic inch or a cubic mile, forming in the process other substances, the only one at present known being helium. It is obvious, therefore, that radium must now be in the course of production. If it had been an original deposit it would have disappeared long ago. It was the merest speculation to discuss how it was produced. Nobody knew, but possibly it came from uranium.

TELEPHONES IN A CONVENTION.—It was decided recently at the St. Louis meeting of the Committee on Arrangements for the convention of the Democratic National Committee to introduce an innovation in the form of telephonic communications between the platform and each of the State delegations at the National Convention in July. The proposal to connect the chairman with all parts of the hall, in order that his attention may be secured promptly by the person first entitled to receive recognition, was accepted after a very brief discussion. In addition to being connected with the State, the chairman will be able to communicate by telephone with the officers of the convention at the doors or any other part of the hall. The importance of the innovation will be appreciated by all who have attended a national convention. Outside of the main hall, the telephone service will be extended to the lobbies, where many additional instruments will be installed, affording long-distance connections.

Letters to the Editors.

Reciprocating vs. Turbine Engines.

To the Editors of Electrical World and Engineer:

SIRS:—Referring to Mr. Seymour's communication in your issue of April 30, I have as much aversion to entering into anything of the nature of a controversy as Mr. Seymour, and would not ask you for space to reply to his communication were it not for some of his statements regarding the steam turbine, which I feel, if left unchallenged, would leave but a poor impression of the adaptability of the steam turbine for general power purposes. Mr. Seymour says:

"According to his figures (that is, mine), if the vacuum should fall to, say, 21 in. instead of 25 in., which, however, does not seem unreasonable, the capacity of the turbine would be cut down 30 per cent., with a corresponding increase in steam consumption, and under such conditions, with a drop in the steam pressure of 10 per cent., the turbine would not pull its rated load, with by-pass full open."

This, in the face of my statement that all Westinghouse-Parsons turbines are capable of carrying full load without any vacuum at all. The 10 per cent. drop in steam pressure would affect the capacity to about a similar extent, but the falling off of economy would be only 3 per cent.

The figures Mr. Seymour referred to were a mere statement on my part, that for each inch of vacuum above 25 in. the economy of the turbine was affected 3 per cent. to 4 per cent.

With reference to an attendant having to be on the spot to open a hand-operated by-pass arrangement for carrying overloads, would say that where the exigencies of the station demand such a thing, this valve is made automatic and is operated by the governor, in which case the turbine is capable of meeting the most exacting demands of fluctuating loads. I fail to see how this feature is any more "a drag upon both boiler and condenser" than in the case of a reciprocating engine carrying overload by means of an extended cut-off.

At the conclusion of Mr. Seymour's letter, he makes some remarks from which inference might be drawn that the economy of a turbine is likely to fall off with age. Experience of five years in this country shows absolutely no deterioration of the working parts, on which condition the economy depends. European experience has been similar in this respect, tests having demonstrated that there has been no falling off in economy.

PITTSBURG, PA. FRANCIS HODGKINSON.

Electric Conductors in Pipe Galleries.

To the Editors of Electrical World and Engineer:

SIRS:—The report of the Plans Committee of the Rapid Transit Commission having again brought the question of pipe galleries prominently to the front, I ask permission to comment briefly on the editorial remarks in your issue of April 16, suggested by the fire in the subway at Broadway and Fulton Street, which temporarily threw out of service so many telephone and telegraph circuits. Your editorial conclusion appears to be that this accident, instead of furnishing an argument for pipe galleries, supplies one against them. Obviously, if the subway had not been built the wires would not have been disturbed, and what happened would not have happened. It may also be true, as you say, that "in most of the pipe gallery schemes which have been discussed from time to time, the plan has been broadly that of carrying the cables in masses through an open tunnel, thus exposing them throughout their entire length to the danger of just such an accident as that which has occurred, and which will inevitably occur again unless greater care is taken."

The prospect of following foreign practice which, in several cities, has given excellent results, does not alarm me as much as it probably would if I had been at less pains to learn what results have followed the crude methods of pipe gallery design which were originally proposed for New York. Permit me to quote further from your editorial comment as follows: "At first glance, the pipe gallery idea has many recommendations, particularly in the ready accessibility of the various services and the facility with which new services can be installed, thus, for example, rendering new competition feasible, which to-day does not appear easy to effect. On the other hand, it does seem as though in working out a pipe gallery scheme, the first consideration should be given to dividing up the services rather than bunching them, so that as in a sectional water tube boiler, the danger would be lessened rather than increased." In the pipe galleries designed for lower Broadway by direction of President Cantor, of Manhattan, at least average intelligence was displayed in planning to accomplish exactly what you deem necessary. Not only did every conductor have its own vitreous conduit encased in cement, but the systems were so divided that the light and power wires were wholly separated from the signal wires, and access to them was had through separate manholes. There was absolutely no connection between the ducts for electric conductors of either class and the chambers containing gas or water pipes. In these respects the system was beyond intelligent criticism, unless based on the ground that it embodied refinements which nothing in foreign experience shown to be necessary for the protection of the public or of private interests. To the engineer responsible for this design it seemed wise to err on the side of safety, and in submitting his plans to President Cantor to say: "Foreign experience in safely grouping high-tension and low-tension electrical conductors, gas mains and water mains in common chambers would seem to indicate that in designing the pipe galleries for lower Broadway excessive regard for safety has been shown in giving the electrical systems ducts in which not only are the high and low-tension wires completely separated, but are wholly removed from even proximity to gas mains. This seemed desirable, if not necessary, in the present instance, but I am of the opinion that in future work of like character the foreign practice may be more closely followed with economy and safety."

The foreign practice here referred to may be learned from the typical example of the pipe galleries built and building by the London County Council, under such of the thoroughfares of that city as are improved in a large way. A sectional drawing given me by Mr. Maurice Fitzmaurice, chief engineer of the County Council, shows the pipe gallery of the Victoria Embankment. It is an arched tunnel without divisions or partitions. Besides the water mains, it contains two 30-in. and one 36-in. gas mains, and a smaller gas pipe of probably four or six inches. The electric wires are disposed of by stringing them on racks dependent from the crown of the arch or on trough-like shelves against one of the side walls. Nothing cruder in design could be imagined, but the system works very well and gives no trouble. The water mains do not break or leak, and an occasional low place where any water which gets on the floor of the gallery may run and be removed by the attendants in pails, is all that is found necessary. There is no gas leakage. Mr. Fitzmaurice, who visits the tunnels daily, assures me he has never noticed even the odor of gas. Permits are freely issued to plumbers to take torch lamps into the galleries, and to maintain naked flames for soldering purposes. I was myself invited to walk through the system with the chief engineer, and was told that I might smoke cigarettes the whole distance. The only persons not permitted to smoke in the galleries are the workmen, and the prohibition applies to them only during working hours.

I make no pretension to being a practical electrician, but the piling of cables one on another in troughs and on hangers suggested an inquiry as to what happened when crosses and short-circuits were established. I was told this rarely occurred, and that when it did nothing happened.

The fact of the matter in few words is that gas and water mains in tunnels do not leak, and that very crude appliances for keeping electrical conductors out of the way appear to serve their purpose very well. The dangers to be apprehended from pipe galleries are wholly imaginary; their advantages are almost incalculable, and without them New York can never hope to attain the character of a city of the first class.

NEW YORK CITY. JAMES C. BAYLES.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Variable-Speed Motors.—PUNGA.—An article on the design of direct-current motors for variable speed. The commutation is by far the most important factor and to get good commutation it is necessary that the number of armature turns per segment is kept small; that the number of lines of force entering the armature is large; and that the effective length of one turn as well as the free length are small. He gives some rules how to alter the design of a constant-speed motor, so as to obtain a good commutation for variable speeds. If the commutator cannot be decreased in diameter and the width of a segment cannot be decreased, then the most effective way to obtain the end in view is to increase the diameter of the armature, keeping the length constant. These deductions are valid only if mechanical difficulties do not prevent an increase of the armature diameter; if the corresponding speed motor has sparking for its limit of output, and if the number of turns per segment is larger than one. These provisions are discussed in detail. The general conclusions arrived at by the author are discussed for the example of a 7-hp, 125-volt semi-enclosed motor. Special devices for the prevention of sparking may be profitably used in variable-speed motors of a wide range. It is thought that a smooth-core motor fits admirably the requirements of the variable-speed motor, because the amount of copper employed is very small, causing only a slight increase of the air-gap. This motor should be designed with small diameter and large length of armature, since this affords the greatest advantage to the use of the smooth-core winding.—Lond. *Elec. Rev.*, April 22.

Predetermining the Regulation of Alternators.—TORDA-HEYMANN.—A paper illustrated by diagrams in which he develops a theoretical basis for the experimental predetermination of the regulation of alternators with reference to a former paper of Behrend (ELECTRICAL WORLD AND ENGINEER, 1903, Vol. XLII, p. 802). The regulation is defined as the drop in voltage which occurs when full load is put on the machine, excitation and speed remaining constant. His method is a graphical one and is based on the knowledge of the following three curves: First, the no-load saturation curve; second, the short-circuit curve, and third the apparent magnetic resistance curve. The abscissæ are in all cases the excitation in field ampere terms while the ordinates in the first curve represent the e.m.f. at the armature terminals, in the second curve the current in the short-circuit armature and in the third curve the apparent magnetic resistance of the alternator which is the ratio of field ampere terms to the e.m.f. of the generator. By means of these three characteristic curves the voltage drop on inductive load with power factor zero may most accurately be obtained by a simple geometrical construction. For other power factors, then, the regulation is easily determined by well-known methods. The method is described in detail and applied to various examples.—Lond. *Elec.*, April 22.

LIGHTS AND LIGHTING.

Gas Versus Electric Lighting.—BOOTH.—An article on the advantages of modern gas lighting over electric light. The author says that for 100 years little or no improvement has been made in the methods of using gas. Nor was it looked upon as good policy to encourage systems of gas burning which made for economy. The standard of gas light was a paltry 16 cp from a flame burning at the rate of 5 cu. ft. of gas per hour. Now, the Welsbach burner using 3 to 8 cu. ft. of gas per hour, gives 18 candles per cu. ft. The present condition of gas lighting is such that the mantle bars the way to any further improvement, but with better mantles there can be better efficiency. "At present with one of the current systems a thousand feet of gas, at three shillings per thousand feet, will produce 36,000 to 40,000 candle-hours, or 1,000 to 1,100 candle-hours for one penny; that is to say, fully 20 hours of 50 cp for one penny. Users of electricity may compare their bills on the basis of three lamps of 16 cp each, run for 24 hours, and they will perceive how exceedingly extravagant a light is that from electricity." Gas lighting with modern methods is claimed to be at present far ahead of electricity in all respects, save convenience, and, under ordinary circumstances, health. Electricity lends itself to situations for which gas is out of question; but it is thought that for plain, straightforward lighting of rooms, workshops and public buildings, it is very doubtful whether electricity will hold first place in any sense of the term. It is pointed out that the "machinery of electric light" has become more complicated instead of simpler as time has moved on. "In coal consumption the incandescent electric light probably demands three times as much as modern gas lighting." It is thought that the hope for electric lighting at present lies in the direction of the arc light.—*Cassier's Mag.*, May.

POWER.

Steam Turbines.—An illustrated description of the power plant of the Yale & Towne Manufacturing Company, of Stamford, Conn., which is the first factory plant which has adopted the steam turbine in comparatively large units. The Westinghouse-Parsons turbine units are of 400-kw capacity each, giving a total capacity of 1,072 electric hp. The equivalent, at the 85 per cent. over-all efficiency claimed for the units, of about 1,260 indicated hp. The space occupied by the turbines and the surface condenser is roughly one square foot for three indicated horse-power, but this does not include the space occupied by the circulating and hot-well pumps which are in the basement nor the dry vacuum pump which is in another part of the engine room. The turbines with their attached generators weigh 33,200 pounds apiece and are set upon concrete foundations which cost less than $400 for the two machines. The cost of installation erected and ready to run was about 65 per cent. of that of a unit of the same capacity and efficiency operated by a reciprocating engine. The first unit was guaranteed to produce an electric hp-hour on 16.5 pounds of steam at 155 pounds gauge pressure, superheated 40°, and with 28 in. of vacuum. With an over-all efficiency of 85 per cent., this would be 14.025 pounds of the superheated steam per indicated hp-hour. On test with the rated load, 150.92 pounds pressure, 19.66° of superheat and 26.95 in. vacuum, the turbine used 22.156 pounds per kw-hour, or 16.53 pounds per electric hp, or 14.05 per indicated hp. As neither the pressure, superheat nor vacuum were what they should have been, the guarantee is recorded as more than fulfilled. In the same issue a description with detailed drawings is given by Levin of a multiple impact steam turbine.—*Power*, May.

Degree of Uniformity of Prime-Movers.—BERKITZ.—A description of a new method for rendering visible the degree of uniformity of the rotation of prime-movers during one revolution. A disc is loosely connected to the machine axle, but is made to revolve with uniform speed. The movements of the machine in relation to the uniform rotation of this disc are used for displacing the position of a mirror which also revolves. This mirror reflects the rays of a stationary series of light upon a surface, so that curves are described on this surface. The form and area of these curves depend upon the degree of uniformity of speed. From the curves it can, therefore, be determined whether the machine runs with the required degree of uniformity of rotation. A practical method of carrying out this principle is described and illustrated.—*Zeit. f. Elek.* (Vienna), April 17.

Electric Cableway.—An illustrated description of the cableway which has been installed for carrying 4,000 tons of railway construction plant over the Zambesi River in Africa. A special arrangement of steel towers for the cable has been adopted, with a special self-contained electric conveyor, which only requires a copper trolley wire to convey the current to it from the generating station on the bank. The conveyor is suspended on two traveler wheels running on the rope. On a frame which hangs down from the wheels are carried an electric motor, a chair for the driver, and two drums, which latter are actuated by the motor on which the hoisting ropes are wound. The conveyor is capable of lifting and carrying a maximum load of 10 tons, and it is estimated that no less than 800 tons of material can be transported across the river in one day.—Lond. *Eng'ing*, April 22.

REFERENCES.

Coal Mining.—FOWLER.—A long illustrated article on coals and coal mining methods of the Pocahontas field. The article deals mainly with general mining methods and the use of electric power is only occasionally mentioned. For ventilation fans are used from 25 to 40 ft. diameter, with a capacity of 300,000 to 500,000 cu. ft. of air per minute, and are driven either by an individual steam engine or an electric motor, dependent upon the location. If they are near the central power house, and within easy reach of steam, engines are used; but if they are over a distant opening in the outcrop, they are driven by an electric motor. The miners' cars are hauled out by either electric or steam locomotives, though the latter are used in the majority of cases.—*Eng'ing Mag.*, May.

Quayside Cargo Appliances.—CUNNINGHAM.—A fully illustrated description of some modern quayside cargo appliances and especially of electric quay cranes.—*Cassier's Mag.*, May.

TRACTION.

Voltage Drop in the Rails with Alternating-Current Traction.—BEHN-ESCHENBURG.—A paper in which the author first discusses the difficulties which arise from the use of the rails as one conductor in an alternating-current traction system, on account of the disturbances set up in telegraph and telephone lines in the neighborhood, using the earth as return conductor. The Oerlikon Company has made a series of tests on the action of sinusoidal alternating currents of various frequencies on a telegraph relay, a telephone bell and a telephone receiver. The disturbances of telegraph relays and of the frequency from 15 to 50 for a given voltage at the terminals; on the other hand, the vibrations of the telephone membrane will rapidly increase for higher frequencies from 25 to 50 periods. The author concludes that disturbances in telegraph and telephone lines using the earth as return, can only be avoided if the loss of voltage in the railway rails is compensated for. He gives some actual data on measurements of voltage drop in the rails on an experimental road of 400 meters length. He then describes a system of the Oerlikon Company in which the voltage loss in the earthed rails is avoided by diminishing the current in the rails. For this purpose an auxiliary line is provided which is connected to the rails at regular intervals. Only on that section of the road on which a train is just running, the rails carry current, while in all other sections the return current does not flow through the rails, but through the auxiliary wire. The advantages of this auxiliary wire, compared with a second insulated return conductor may be questioned, but the enormous simplification of the collection of the current by means of the wheels of the train is of decisive importance. The scheme is shown in Fig. 1, which shows two sections of the road. *L* represents the auxiliary conductor, while *S* represents the rails. Each section contains a transformer, the primary being in the overhead conductor and the secondary in the auxiliary conductor. By properly designing these transformers it is possible to accomplish that the return current flows nearly throughout through the auxiliary line, and that it flows through the rails only in that section on which the car runs. When they applied this method on their experimental lines it was possible to reduce the voltage loss in the rails 25 times. The transformer must be so designed that its self-induction is very large compared with the ohmic resistance of the section of the artificial conductor and that with this transformer an e.m.f. is produced which is equal to the voltage drop in the section of the auxiliary conductor.—*Elek. Zeit.*, April 21.

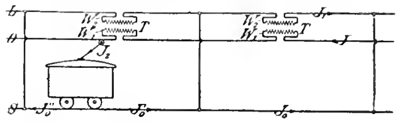

FIG. 1.—ALTERNATING-CURRENT TRACTION.

Petrol Electric Cars.—An illustrated description of the equipment of the petrol electric motor cars, which have recently been installed on the North-Eastern Railway in England. They have a capacity for 52 passengers. The driving power consists of a four-cylinder petrol engine, rated at 80 brake hp at 420 r.p.m. This drives a compound-wound and separately-excited dynamo rated at 55 kw, which supplies current to two 55-hp tramway motors mounted on the front bogie of the car. The exciter is driven by belting from the generator. The exciter is shunt-wound and is also used for running the 30 incandescent lamps of 16 cp and 72 volts, with which the car is lighted, and can further be used to furnish current at 95 volts for charging a secondary battery of 38 cells, each rated at 120 amp.-hours, which is fixed beneath the floor of the car. In starting up, the engine is driven for a turn or two by the generator acting as a motor and taking current from the secondary battery. Once the engine is up to speed and the voltage has been adjusted to 400 volts, the car is started by the controller in the usual way. For slow speeds the car is run with the motors in series, and for high speeds with them in parallel. The voltage of the generator is gradually increased to 530 volts by cutting resistances out of the exciter circuit and the car accelerated until a speed of 36 miles per hour is attained. In stopping the car the controller handle is moved back to the off position, and then over in the reverse direction to supply the magnetic track brakes.—Lond. *Eng'ing*, April 22.

INSTALLATIONS, SYSTEMS AND APPLIANCES.

Small Electric Station.—The first part of a description of small electric plants for little rural towns and summer resorts. The first plant described is that of Mitterfels in Southern Germany, a town of 700 inhabitants. Water power is utilized with a minimum capacity of 12 hp. The two-wire, direct-current system is used with a voltage of 220. A storage battery of 125 cells with a capacity of 10 kw for a three-hour discharge is provided. The price charged for the current is 25 cents per candle-year and, if a meter is used, 12½ cents per kw-hour for lighting and 5 cents for power. The only attendant at the plant is the seventeen-year-old daughter of the proprietor of the mill, which was changed into the station.—*Elek. Anz.*, April 14.

WIRES, WIRING AND CONDUITS.

Eddy Currents in Cable Sheaths.—FIELD.—The conclusion of his paper. The author remarks that in dealing with the sheath losses in multiple-core cables one should form a mental picture of the approximate distribution of the external magnetic field produced at different periods of the cycle by all the currents within. He gives several diagrams and especially one showing the successive distributions of magnetic field around a three-phase cable at six moments within half a cycle. He calculates the possible losses for a three-core, three-phase cable of certain dimensions with an effective current of 200 amp. per core for a frequency of 60. The sheath loss per mile is found to be 0.67 kw. The copper-earthed sheath directly under the lead, now advocated by the British Board of Trade, increases this loss and may bring it up to 2 kw per mile. If the cable is then let in an iron trough or is steel-armored, the total external field will again be largely increased, perhaps two or three times. The author recommends first to wind on the copper strips with a lay as different from that of the cores as possible, and then to apply a thin coat of paint before applying the lead sheath.

This coat of paint will be amply sufficient to prevent eddy currents leaving the copper, but should leakage occur from one of the high potential conductors, this insulation would be either instantly broken down or, failing this, would be sufficiently low to form a thoroughly good earth. He finally considers the case of centric cables. If, on account of faulty manufacture, some eccentricity exists, a cable carrying 200 amp. having an eccentricity of 1/8 in., would produce an e.m.f. in a parallel pilot wire, situated 4 in. away, from 3 to 4 volts a mile.—Lond. *Elec.*, April 22.

Calculating Distribution Networks.—MÜLLENDORF.—The conclusion of his long mathematical article in which he describes a method for calculating a distribution network. Without going into mathematical details, this method is essentially as follows: Feeding points are chosen and the "natural districts of action" are determined for the same. It is then investigated whether one of these districts is relatively too large or too small and whether the feeding points are situated in the centers of gravity of the natural districts of action. For each district the central station is to be taken into account. If this investigation does not lead to any changes in the number or position of the feeding points, the cross-section of the conductors in each district of action is calculated by the simple method of moments of current, and the possible minimum of conductor copper is determined. The network is thus calculated if one does not want to simplify further the cross-section. In the latter case one substitutes the definite cross-section for the former ones and calculates the resulting distribution of the current. The amount of copper thus found is compared with the predetermined minimum. He thinks the value of his method lies in a constant control of the consumption of copper and in the simplicity of the method of controlling it.—*Elek. Zeit.*, April 21.

Testing Networks.—A long editorial on regular tests of electricity supply networks. It is pointed out that they are often neglected, although periodical tests of the insulation—actual quantitative measurements—can be carried out with instruments no more delicate than those which are erected on the switchboard of every modern station, and by men possessing only a very limited knowledge of electrical engineering. It requires a little more to be able to appreciate the exact nature and principle of the tests and the suitability of the instruments used, but a station engineer should have this knowledge. The same applies to fault localization. By carrying out simple instructions there is no reason why even the shiftiest shift engineer should not be able to localize a fault within a network within a yard or two and eliminate it with far less disturbance to the continuity of supply than by means of the cut-and-try method. Of course, there is room for refinements and faults should be discovered and removed before they have become bad enough to do any damage.—Lond. *Elec.*, April 15.

Electro-Physics and Magnetism.

Vacuum Tubes.—TAYLOR.—When electrical energy passes between the electrodes of a vacuum tube, the discharge may be either direct or alternating, continuous or disruptive; but not much is known, except in the case of the continuous discharge, concerning the variations in potential which occur in any of these cases. The author has made a series of experiments in this direction, using first calorimetric methods. Afterwards it was found that better results could be obtained by means of the Braun tube, with which he could determine not only the potential difference with considerable accuracy, but could also observe the variations of potential and the frequencies of discharge. It was found that the potential rises to a certain maximum height and then suddenly falls off to a minimum value, but never to zero, although the maximum and minimum values for any tube depend upon the particular conditions under which the tube is tested. He describes a method by which the Braun tube can be conveniently used to measure high potentials, of say, 1,000 or 1,200 volts, where the fluctuations are not too great. When the limits of variations are great, say 500 volts or more, the problem is more difficult, but the author describes a method for such cases. The measurements of the author show that the manner in which the potential develops and falls off is very largely effected by the capacity of the circuit.—*Phys. Rev.*, May.

Hall Effect in the Electric Arc.—CHILD.—An American Physical Society paper on the phenomenon that if two carbon pencils are so placed in an arc that there is little or no potential difference between them, a potential difference is produced by creating a magnetic field about the arc. This may be as high as 1.5 volt. It appears to be similar to the Hall effect in metals, and if it is this effect it would show that the negative ions have a velocity enormously greater than that of the positive. He describes several observations made concerning this effect, but says that no definite explanation can at present be given.—*Phys. Rev.*, May.

Conductivity and Electrostatics.—VON NICOLAJEW.—A paper in which the author points out that conductivity should enter into electrostatic formulæ as often as the specific inductive capacity, and that the neglect of the factor makes modern electrostatics too much of a fiction. He quotes some experiments in electrostatics, in which the conductivity plays a more important part than the inductive capacity, and yet is usually left out of account. A piece of paraffin suspended in air beside a charged conductor is attracted by the latter owing to its higher dielectric constant. If the conductivity of the air were very much higher than that of the paraffin, the latter would be repelled instead. If the medium and the suspended body have nearly the same dielectric constant, the effect of the conductivity may very well mask that of the dielectric constant.—*Phys. Zeit.*, April 1; Lond. *Elec.*, April 22.

REFERENCE.

Radioactivity.—MARCKWALD.—A paper read before the Berlin Electrical Society in which he gives a review of the researches of various investigators on radioactive substances.—*Elek. Zeit.*, April 21.

Electro-Chemistry and Batteries.

Storage Batteries.—A review of new developments in the storage battery line during the last year or so. It is based mainly on patent specifications, but it is pointed out that most of the patents in this field would not have been taken out if the inventors had not been quite inexperienced. It is stated that the large manufacturers now care less and less for inventions which may be theoretically pretty but are practically worthless, and they try to make accumulators of the most simple construction. For this reason the makes of different firms have become so similar that the accumulator business has nearly become "trading in lead." Concerning electrolytic methods of formation, it is stated that all methods which have been found practically effective, are based on the use of an anion which is able to form a lead salt, soluble in water. Under suitable conditions lead peroxide is formed at once, without a previous production of lead sulphate. It is said that this is an interesting reaction which appears to be related to the passivity of iron, chromium and nickel electrodes and which should be studied more thoroughly not only for technical but also for scientific reasons.—*Zeit. f. Elektrochemie*, April 15.

Glass Furnace.—A note stating that electric furnaces are giving good results at the large glass factories at Matrey in Tyrol and at Plattenburg, in Westphalia. In the latest type of furnace the raw material, before it is exposed to the heat of the arc, is made into a paste with water. It is then pressed and dried and finally it passes in the shape of a ribbon through the arcs between a number of electrodes, out of which it emerges completely fused. The heating is chiefly done by radiation and care is taken to prevent impurities from carbon entering the molten glass.—Lond. *Elec. Eng.*, April 15.

Chemical Engineers.—HERRESHOFF.—A long abstract of an American Chemical Society paper on the training of the chemical engineer. What is needed now in chemical industries is not a chemist, pure and simple, but one who has, besides chemical training, a full knowledge of physics and mathematics and a thorough training in engineering. There was a long and animated discussion in which chemical engineers and professors equally participated. There was unanimity concerning the desirability of such a training, but it was doubted that this could be accomplished with the present system of university instruction.—*Electrochem. Ind.*, May.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Practical System of Units.—ROBERTSON.—A communication in which he remarks that four fundamental quantities are really necessary for a system of electrical units, length, mass and time usually being three of them. In the electromagnetic system, magnetic permeability is taken as the fourth, that of air being the arbitrary unit. The writer recommends to take as the four fundamental or arbitrary units the meter, kilogram, second and ohm (defined from a mercury or wire standard). We thus get a complete system which includes all the established practical electrical units and gives units which have a convenient magnitude for most purposes. Instead of resistance we may take electric quantity, with a coulomb defined from the electrolysis of silver, as the fundamental unit. One advantage of this would be that the dimensions in terms of the fundamentals would have no fractional indices, but the material standard is not quite so direct. He recommends to define the permeability and the specific inductive capacity in such a way that the well-known 4π disappears in most formulas; under these conditions the permeability of air is $4\pi \times 10^{-7}$ henrys per meter, and its specific inductive capacity $(1/36\pi) \times 10^{-9}$ farads per meter. Instead of kilogram he recommends to write k'gram or kram. The name newton is suggested for the unit of force (10^5 dynes), but new names should not be given to other units. Compound names should be used like volt-second for the unit or flux and volt-second per square meter for the unit of flux density, etc. The giving of new names only results in confusion. It is also undesirable to have too many prefixes for sub-units. Only those representing powers of 1,000 have been found really useful and the others should be abandoned.—Lond. *Elec.*, April 22.

Electrical Notation.—EMDE.—A communication discussing the use of various types of letters for notation in electrical engineering and in physics in general. His suggestions cannot be shortly abstracted, but it may be mentioned that the author does not propose to try and get an international system of notation. He thinks it would be valuable only on paper, but not in practice. "German books are mostly read by Germans. If they are translated the symbols may also be changed. If a foreigner overcomes the difficulties of the German language, German symbols will not disturb him." He does not think that *W* for resistance and *A* for work (derived from the German words Widerstand and Arbeit) would be unsuitable for international use.—*Elek. Zeit.*, April 21.

Direct-Reading Instruments.—EDGCUMBE AND PUNGA.—The conclusion of their paper read before the British Institute of Electrical Engineers, on direct-reading measuring instruments for switchboard use. They describe methods of connecting wattmeters for the measurement of power.—Lond. *Elec.*, April 8. The extended discussion which followed the paper is abstracted in Lond. *Elec.*, April 8 and 22. In an editorial it is said that instrument users rather than instrument makers should derive most profits from the discussion and from the paper. They can learn what accuracy to expect from the instruments and one source of serious errors which is too often disregarded has been pointed out, viz.: parallax. Nignoles stated this is especially troublesome with the "edgewise" instruments, in which the angle between the direction of the observer's vision and the instrument scale differs enormously for different readings. It is only on account of the parallax error that "set up" or "open scale" instruments are more accurate than those with equally divided scales, for the percentage accuracy of the instrument itself if the same in the two cases, if the instruments are otherwise similar. Ayrton called attention to the stray field due to the bus-bars. Some switchboards are designed in such a way that the instruments could not possibly be accurate unless they were calibrated in position, and even on the best-designed direct-current switchboard there are magnetic fields, dependent on the current through the bus-bars, which may be troublesome if the instruments are not sufficiently well sheathed. Nalder pointed to an error that could arise from the screening iron case itself.—Lond. *Elec.*, April 22.

TELEGRAPHY, TELEPHONY AND SIGNALS.

Wireless Telegraphy.—BRAUN.—An illustrated article on methods for increasing the transmitter energy of wireless telegraph systems. In so-called closed circuit ("coupled") systems the open circuit of the transmitter is not directly excited, as was the case with the first Marconi arrangement, but is connected with an oscillatory circuit containing condensers and self-induction and serving as an energy reservoir. There are two theoretical possibilities of increasing the energy; first by increasing the capacity, and second by raising the charging voltage. The author shows, however, that both methods have their limitations. He has, therefore, searched for methods which—without altering the frequency of oscillations—would allow the energy disposable for radiation to be decreased in such a manner that the economy of a single jar circuit is retained. Various arrangements of this kind are described. One is shown in Fig. 2 in which the condensers, *C*, are charged in parallel and are connected for

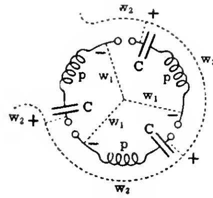

FIG. 2.—WIRELESS TELEGRAPHY.

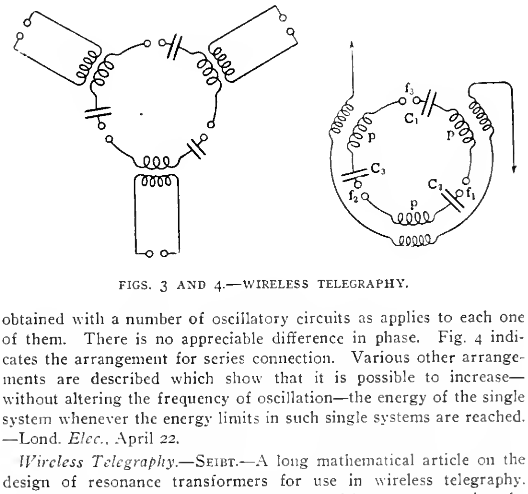
this purpose with non-inductive or inductive resistances, *w*. As soon as one spark occurs, the whole circuit closes within itself. The large charging resistances are then practically inactive. If wholly unforeseen peculiarities of the spark do not exist, then the spark will also act in the same manner as in a single system. It is possible to obtain, as in Fig. 3, the same effects (final voltages, heating effects, etc.) simultaneously on each of three artificial transmitters which are tuned to one another. The same efficiency is, therefore,



FIGS. 3 AND 4.—WIRELESS TELEGRAPHY.

obtained with a number of oscillatory circuits as applies to each one of them. There is no appreciable difference in phase. Fig. 4 indicates the arrangement for series connection. Various other arrangements are described which show that it is possible to increase—without altering the frequency of oscillation—the energy of the single system whenever the energy limits in such single systems are reached. —Lond. *Elec.*, April 22.

Wireless Telegraphy.—SEIBT.—A long mathematical article on the design of resonance transformers for use in wireless telegraphy. The author remarks that the hopes that had been set on tuning the transmitting and receiving stations to the same frequency have been fulfilled in practice only to a very small degree. In order to protect one's self against disturbances from other stations, the only means is at present to diminish artificially the receiver intensity and to increase the transmitter intensity. This means the necessity of radiating larger and larger quantities of energy. This is now possible. The author finally asks whether Marconi utilizes the resonance of the slow oscillations in his large stations. He says that, according to his calculations, this would be possible only if he had provided his transformers with an air-gap of several centimeters.—*Elek. Zeit.*, April 17.

Nickel in the Core of the Marconi Magnetic Detector.—An account of experiments on the changes of sensibility of a magnetic detector as a function of the varying distances between the moving magnet and core. Since nickel is more susceptible than iron in weak magnetic fields and less susceptible in strong fields the author thought that a more uniform sensibility for varying distances might be obtained by making the core of nickel. He found that the sensitiveness of the detector with a nickel core was not very different from the sensitiveness when an iron core was used. Contrary to expectations, however, the sensitiveness with the nickel core appeared to be greater in stronger fields and with the iron core in weak fields. Both show a maximum of sensitiveness at a short distance from the magnet, the maximum for nickel being the farther removed. A mixed core consisting of annealed piano wire and hard-drawn nickel wire produces a more sensitive detector than using a core of piano wire alone.—*Phys. Rev.*, May.

New Books.

WHITTAKER'S ELECTRICAL ENGINEER'S POCKET BOOK. By Kenelm Edgcumbe. London: Whittaker & Co. 444 pages, 149 illustrations. Price, 3 shillings, 6 pence.

While this book belongs in the familiar class of engineers' reference books, it differs in plan from most of those which have previously appeared in that the compiler does not content himself with assembling all the formulæ and empirical data that may be available on given subjects, without any indication to the reader as to which of conflicting rules or formulæ are most generally used or accepted; a clear-cut synopsis of each subject is given. The first 47 pages are devoted to mathematics and physics and contain the usual logarithmic and trigonometrical tables, tables of weights and measures, circular functions, etc., as well as brief discussions of the elementary principles of mathematics and physics. Next, practical mechanics are treated briefly, and then the electrical part proper is reached. There are imperfections, of course; whoever saw a first edition free of them? In the table of units, for example, the practical English unit of acceleration is said to be feet per minute per minute and that of angular velocity to be revolutions per minute. On page 98 we are told that "the C. G. S. unit of inductance is, therefore, the unit of length, i. e., the centimeter," which is news, to say the least. On the whole, however, the subject matter is accurate. The sections on measuring instruments, direct-current and alternating-current dynamos and motors and testing generators and motors are particularly good. The methods of dynamo and motor design outlined in the dynamo and motor sections are thoroughly practical, although somewhat too condensed to be useful without the aid of the more detailed treatment to be found in books devoted exclusively to that subject. The section (if two pages may be so termed) on storage batteries is about as unsatisfactory as those just mentioned are praiseworthy; the paltry amount of information that is given is accurate, but the scope is so limited as to make the discussion negligible. This is also true of arc and incandescent lighting, which has been accorded the space of four pages. With the proper balancing, which the book will doubtless receive in the course of future revisions, Mr. Edgcumbe's work will be of much value to his fellow engineers.

DIE ELEKTROMETALLURGIE DER ALKALIMETALLE. By H. Becker. Halle: Wilhelm Knapp. 128 pages, 83 illustrations. Price, 6 marks.

This work on the electrometallurgie of the alkali metals, containing 135 pages and 83 figures, forms the ninth volume of the "Monographien über angewandte Chemie," but in itself forms an independent work. The first few pages are devoted to the methods of obtaining the alkali metals by chemical means, and as this lays practically outside the scope of this work, little stress is laid on this chapter. The author's object in introducing this chapter is evidently only to show in how far the chemical and electrochemical processes are identical, and then to demonstrate how much easier and more economically the processes can be performed with the aid of the electric current. The rest of the work is a careful and full description of the existing patents for the manufacture of the alkali metals, to which Becker has added his remarks.

The greatest stress has been laid on those processes which are in actual operation to-day; in other words, those which proved commercially successful. Among the successful ones belongs also a process of the author's, and the remarks he adds to some of his competitor's processes, are somewhat bitter and sometimes misleading. In more than one case his information is erroneous and lacks accuracy. He thus states that he does not know whether Castner's process in England is operated by the Castner-Kellner Company or by the Aluminum Company, and it certainly would not have cost him much trouble to ascertain, that the process is operated by the Castner-Kellner Alkali Company, Limited, in Runcorn. The information and illustrations about the Darling process are very interesting, but instead of stating that the same did not prove a commercial success and never passed its experimental stage, he states that it is in operation at the Harrison Bros'. works, in Philadelphia, which is entirely erroneous, although the experiments were carried out in their factory. He also hints that possibly the Darling process is of more commercial value than Castner's process, which is operated at Niagara Falls. Castner's process seems to be a thorn in the author's side; but this is explicable, as his (Becker's) process is operated at the Usines de Rioupéroux works in Isère, France, and Castner's at the Cie de Electro-Chimie, also in Isère. The author tries to minimize the value of Castner's process at all points, but we must consider that this process is possibly the best, as it is the only one which is operated in the United States, England, Germany and France; whilst Becker's process is only working in France and perhaps now in Germany, but apparently not with equal success to Castner's.

In his chapter on the uses of sodium, his information on its application for the production of cyanide is entirely wrong. He states that most of the cyanide produced at present is made by the older method with potassium ferrocyanide and sodium, and that the newer method of making the same, with sodium, charcoal and ammonia gas, is not in operation; this hardly coincides with the fact that both in the United States and Germany certain cyanide factories dispensed with the first method and are, since at least four years, successfully operating the second process, even at the low prices they have to meet to-day. One can, however, easily reckon out that the latter process would still be the cheapest process for the manufacture of cyanide, even if the results were not of the highest efficiency. Becker ends his work with three very complete tables, giving the numbers of the patents described, their inventor and other interesting information in regard to the same.

FREE-HAND LETTERING. By Victor T. Wilson. New York: John Wiley & Sons. 95 pages, 13 illustrations. Price, $1.00.

Much of the draughtsman's success depends upon the appearance of the finished drawing, and no part of it contributes so forcibly to the production of a pleasing impression as correctly designed and neatly executed lettering. In the past draughtsmen's alphabets galore have been published, but these have usually been merely pictures of various styles of lettering which the draughtsman was left to copy either enlarged or reduced, as might suit his purpose.

The present volume departs distinctly from previous precedents in that it attempts to be a scientific treatise upon the principles of lettering, and endeavors to convey the methods by which titles should be designed and executed, rather than to furnish examples purely for copying.

The work consists of seven chapters, the first of which deals with the history of alphabetic characters and the principles which enter into the construction of roman and gothic letters. Chapter II takes up the question of spacing and shows that there is no mathematical rule governing proportioning but that spacing must be altered with the type of letter and with the effect which the draughtsman desires to produce. Then come instructions in the use of the pen and in that off-hand lettering which is becoming more and more popular in all classes of drawings. Chapters IV and VI deal respectively with the designing of titles and the design of letters. Chapter V introduces instructions for special technical lettering such as that required for photographic reproduction, while finally Chapter VII takes up the various mechanical aids to good lettering.

The underlying thought in the volume is that lettering like other forms of art is a method of expression that cannot be done purely mechanically, and that unless the draughtsman is able to design free hand it is impossible for him to become a perfect letterer.

ELETTROCHIMICA. Soda Caustica, Cloro e Clorati Alcalini per Elettrolisi. Ing. F. Villani. Milan: Ulrico Hoepli. Price, 3.50 lire.

This is one of the manuals of Hoepli's well-known series. Three hundred pages deal with electrolysis of aqueous solutions and 15 with electrolysis of fused salts, but of the great number of industrial processes, in use on a large scale, those best known in this country, like the Castner-Kellner and the Acker processes receive no attention. On the other hand, the author's own process is described at length and a large amount of interesting information is given concerning it. The chapters on volumetric analysis and on the continual supervision of an electrolytic caustic soda and bleaching plant also contain much useful information for the specialist in this field.

National Association of Manufacturers.

This Association will hold its ninth annual convention on May 17, 18 and 19 at Carnegie Hall, Pittsburg. The headquarters are at the Hotel Schenley, nearby, in a pleasant part of the city. A good convention is expected by Mr. Marshall Cushing, the secretary.

Electrical Exhibits at the Opening of the St. Louis Exposition.

THE large number of completed and operating exhibits, and the condition of the Electricity Building on the opening day, April 30, received favorable comment from all visitors. While there is considerable installation work to be done in many spaces, on that Saturday exhibits were attractively arranged, aisles were cleared, and the building as a whole made a neat appearance. The accompanying photographs were taken of the several exhibits as they appeared at that time.

The handsome booth of the Bristol Company is located in Section 36, and contains a large variety of recording instruments, for pressure,

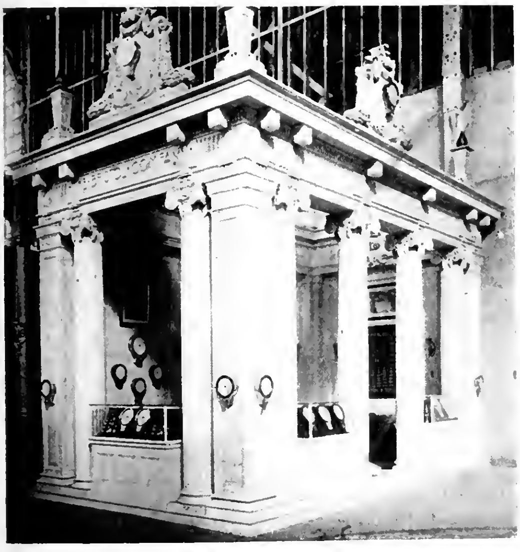

FIG. 1.—BRISTOL COMPANY'S BOOTH.

temperature and electricity. These instruments record continuously and automatically with ink, upon graduated revolving charts, all changes that occur in pressure, temperature or electricity, so that the record after a period of twenty-four hours or more may be observed at a glance. Many of these instruments are in actual operation, and demonstrations will be made for visitors, showing the manner of construction, the scientific principles upon which the operations depend, and the extreme sensitiveness and accuracy that it is possible to attain in instruments of this character without rendering them too delicate for commercial application. Recording pressure gauges are shown for all ranges from full vacuum to 10,000 pounds per square inch. Also recording thermometers and pyrometers for ranges from 60° below zero to 1,000° F. The recording thermometers are made in many varieties of form to make them applicable to all industrial requirements, especially where it is desired to record tem-

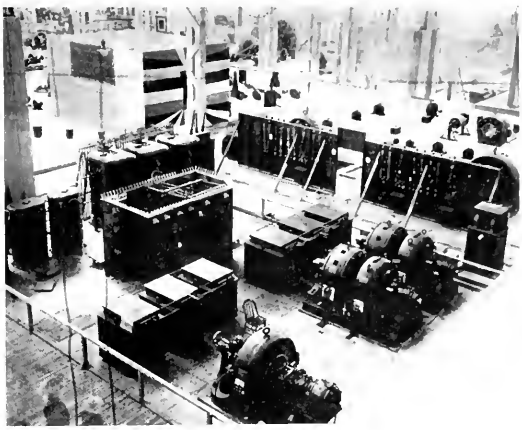

FIG. 2.—SUB-STATION.

peratures at a distance from the source of heat. Recording volt, ampere and wattmeters, for both alternating and direct current, are shown, including a great variety of ranges suited to commercial demands for different voltages and currents in electric light, power and railroad plants. Recording water gauges in operation and a new instrument designated as a thermometer-thermostat will be shown.

The exhibit of the Baldwin Locomotive Works in the northwest corner of the building comprises electric locomotives and electric

FIG. 3.—BALDWIN LOCOMOTIVE.

railway trucks for various conditions of service. The locomotives shown in the photograph include the following: A ten-ton machine equipped with two 50-hp Westinghouse railway motors constructed for the Berwind-White Coal Mining Company, adapted for heavy and frequent service in the coal mines of Western Pennsylvania: a fifteen-ton locomotive constructed for the Norfolk Coal & Coke Company, for use in the mines of West Virginia, where coal has to be handled on the surface in all kinds of weather and conditions of track; an electric locomotive built for surface work, of special design, permitting powerful motors of standard construction to be mounted, adapted to run on track of extremely narrow gauge. The machine exhibited is for operation on a track gauge of 24 in., and at the same time carries two Westinghouse railway motors of 35 hp each. The electric railway trucks consist of one constructed for the Interborough Rapid Transit Company, of New York, and designed for heavy elevated passenger service; one for the Illinois Central Traction Company, designed for high-speed interurban service; and also one for light work. All trucks shown are of M. C. B. design and equipped with Westinghouse Electric & Manufacturing Company's railway motors.

The operating exhibit of the Bullock Electric Manufacturing Company represents the high development of this company as a manufacturer of electrical apparatus of all kinds. The space includes all of Section 15, and is 54 by 104 ft. In the center is erected an ornamental pavilion, handsomely finished and comfortably furnished. Motors direct-connected to machine tools, requiring variable speeds and operating on the multiple-voltage system, in practical operation, are shown in the Bullock exhibit. The main generator furnishes current at 250 volts, and a balancer splits the voltage into 60 and 160 volts for distribution. An engine lathe, a milling machine, a boring mill and a shaper, all direct driven by Bullock motors, will be operated by this set. This gives three fundamental speeds, but by the proper insertion of shunt field resistance twelve speeds in the forward direction are obtained, and nine in the reverse. The controller used in connection with this system is so constructed that a careless operator cannot stop the handle between the voltages. The motors when enclosed are supplied with spun metal covers, particularly adaptable for dirty, damp or dusty places.

The five alternating-current generators on exhibition range in size from 50 to 350 kw in size. An interesting feature in the design of these alternators is that the magnetizing coils of the field are

FIG. 4.—BULLOCK ELECTRIC AND MANUFACTURING COMPANY'S EXHIBIT.

made of strip copper wound on edge. This permits as high peripheral speeds as are possible for steel wheels without windings.

The exhibit includes two heavy street car trucks, on each of which are mounted two 50-hp Bullock street car motors. These are duplicates of the 300 motors now being supplied to the Boston, Haverhill & Manchester Electric Railway Company. The motors will be turning over with current at 500 volts furnished by the 500-kw Bullock railway rotary converter. Alternating current is obtained from the Bullock 3,500-kw, 6,600-volt generator installed in the Allis-Chalmers Company's exhibit in Machinery Hall, reduced in a Bullock 150-kw, oil-filled, self-cooled transformer. There are three of these transformers to be seen in the exhibit. The case of the transformer is made of corrugated sheet steel, which makes it considerable lighter than if it were made of cast iron, as is usually the custom.

The Western Electric Company's space occupies 5,764 sq. ft., having frontage on two main aisles of 88 ft. 5 in., and a width of 65 ft. 2 in. In the center is a motor-generator equipment, consisting of two 100-kw frames, the motor side taking current at 500 volts, and the generator side delivering current at 220 volts. This unit operates in conjunction with a 15-kw compensator, permitting the use of 110-volt current. The center space also contains two switchboards, one for controlling the operation of the apparatus receiving current from the motor-generator, and having all the necessary switches, circuit-breakers, ammeters, etc. The other board is for display purposes only, and on it are circuit-breakers, knife switches, voltmeter switches and kindred apparatus.

In the extreme northeast corner of the space a small machine shop is installed showing the actual operation of modern machine tools driven by Western Electric motors on the three-wire multi-voltage system. West of the machine shop are several direct-connected and belt-driven generators, and a number of Cornish cycle engines direct-connected to generators; these sets being especially for marine use. In the northwest corner of the space are a line of power motors arranged in the form of a pyramid, the smallest ones at the top. In the southwest corner is a series alternating arc light

FIG. 5.—WESTERN ELECTRIC COMPANY'S EXHIBIT.

equipment, consisting of a full line of transformers, regulators and switchboards. Opposite this are ornamental arc lamp stands from which are suspended various types of arc lamps. There are also a number of sewing machine motors in operation. Fan motors and ceiling fans will be distributed throughout the space, suspended from overhead, and a number of boards containing supplies manufactured by the leading companies throughout the country.

Above the space of the Electric Storage Battery Company is a large map of the United States, approximately 40 ft. by 25 ft., which indicates the location of each of the 1,700 electric battery installations made by this company. These are shown by different colored spots of isinglass about one inch in diameter, which will be illuminated by incandescent lamps mounted behind the map, the different colors being as follows: Red lamps for railway plants; blue lamps for Edison plants; white lamps for telephone and telegraph plants, and green lamps for isolated plants. Beneath the map is a model battery house, constructed on exactly the same lines as one forming part of a power house or sub-station equipment. The battery house is of fire-proof and acid-proof construction, properly ventilated and with acid-proof brick floor. A small booster is operated in connection with this battery, and a complete switchboard installed with recording instruments to show what work the battery is doing on a fluctuating load, and also how constant the load is maintained on the generator or bus-bar circuit. The fluctuating load is provided either by switching on or off banks of lamps, or starting up a motor load with brake attached. A railway booster of about 100 kw complete with switchboard and regulator is shown, the motor being connected so that the machine can be run light. A complete line of switchboards for Edison lighting work, isolated plants, railway booster equipment and line batteries; a set of three motor-driven end cell switches connected up complete with motor control and indicator apparatus; complete cells for railway work, such as are installed for the St. Louis Transit Company, and cells of smaller type are set up to show the various types and capacities. A complete exhibit of vehicle batteries for automobile and locomotive work is shown, as well as a collection of photographs and curves as to existing plants and results obtained in them.

The exhibit space of James Clark, Jr., & Co. contains a group of electrically-driven machine tools, small motors and generators and

FIG. 8.—ELECTRIC STORAGE BATTERY COMPANY'S EXHIBIT.

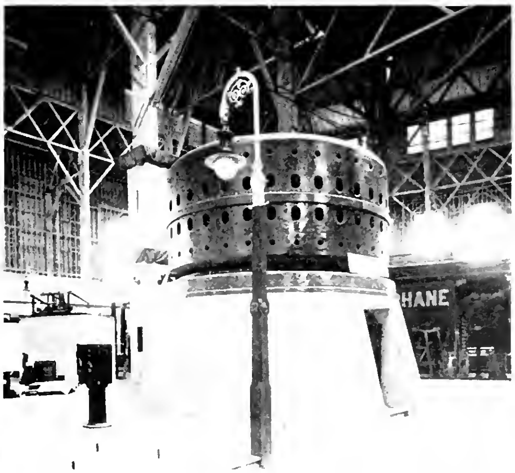

FIG. 11.—PART OF GENERAL ELECTRIC COMPANY'S EXHIBIT.

SOME OF THE ELECTRICAL AND KINDRED EXHIBITS AT THE ST LOUIS EXPOSITION a new variable-speed motor. These electrically-driven tools all have their driving motors built into the machines forming integral parts of them. The exhibit includes a five-foot radial drill, 22½-in. upright drill, automatic armature disc notching machine, a machine for winding magnet coils for electrical machinery, a 14-in. water tool grinder, bench grinder, shop saw, sensitive drills and several sizes of portable drills and center grinders. The radial drill has the driving motor built into the head of the machine, and drives the spindle through the least possible number of gears. The motor is of their variable-speed type, with nine speeds, which, in connection with the lock gears, gives eighteen speeds for the spindle, any of which are instantly available. The lock gears can be thrown in without stopping and the spindle can be instantly reversed for tapping. The spindle has a quick return, eight positive feeds, depth gauge and automatic stop. The arm is raised and lowered by a plain series vertical motor in the top of the column controlled by the small handle on the side of the column. The column swings on ball bearings and can be clamped in position by a lever. The 22½-in. drill has the same features of control as the radial. A 12-in. sensitive drill with motor directly on the spindle demonstrates the adaptability of the electric motor for machine tool driving. The notching machine and magnet winder are machines which will be of special interest to electrical manufacturers, the magnet winder especially being a new development in this class of machinery. The small electrically-driven breast drills are shown in several sizes. There is in operation a 9-kw motor-generator taking current from the 500-volt mains, and supplying the exhibit with 220-volt current, all of the machines being connected so that they can be shown in operation. Several standard small motors are shown, and a new variable-speed motor, designed especially for direct connection to machinery. It has two commutators and two armature windings, having a ratio of five to three, giving three primary speeds, three variations of each of these being made by field resistance giving a total of twelve speeds at high efficiency.

Japan for the first time has made an electrical exhibit, and, to the engineer, it will appear strange to see Japanese characters upon the name plate of a motor. The material and workmanship of the electrical apparatus are of high order, and it will be interesting to ascertain if the operating characteristics are equal to American and European makes. A small steam-driven generator set is exhibited by the Shibaura Engineering Works of Tokio, also a 150,000-volt testing transformer. The Oki Company, of Tokio, exhibits a fine assortment of telegraph and telephone instruments and switchboards. Several models and photographs of hydraulic electric power stations are shown, as well as charts indicating the advance of electrical industry in the empire. The exhibit is enclosed in a handsome booth of Japanese design and erected by native workmen.

FIG. 12.—AUTOMATIC FIRE ALARM COMPANY'S EXHIBIT.

In the French section the exhibit of the Compagnie Francaise des Cables Telegraphiques consists of samples of cables installed in various parts of the Atlantic Ocean and Gulf of Mexico. The damaged cable shown in the foreground of the exhibit was one removed during the repair of Porto Plata, Martinique, cable after the eruption of Mount Péleé in Martinique, May, 1902.

The full-sized model of the latest type of 10,000-kw generator for the Niagara Falls power plant may be seen in one of the engravings. This occupies the southwest corner of the General Electric Company's space. Its great size makes it a conspicuous object in the building.

The Brazilian space is taken up by a display of telegraph, telephone and fire alarm apparatus, porcelain insulators and maps and charts showing the extent of telephone and telegraph lines in the great republic.

One illustration shows the traveling crane over the main aisle along the west side of the building. The craneway has a span of 57 ft. 5½ in. Upon this is a four-motor, 30-ton electric crane furnished by Pawling & Harnischfeger. A 20-hp, 220-volt motor gives a horizontal speed of 250 ft. per minute, an 8-hp motor gives a trolley transverse speed of 150 ft. The main hoist is equipped with a 30-hp motor, having a speed of 25 ft., and the auxiliary hoist with a 15-hp motor, and has a travel from 30 to 90 ft. per minute. The crane proved very serviceable in the installation of exhibits.

FIG. 13.—PAWLING & HARNISCHFEGER CRANE.

The De Forest wireless telegraph station in the Electricity Building consists of three 75-ft. towers, the bases of which may be seen in the illustration. The sending and receiving instruments are placed near the center of the triangle formed by the towers. The ability of wireless telegraphy to maintain simultaneous communications between a number of stations without interference will here be determined. It is largely with this in view that the De Forest Company decided to equip so large a number of stations upon the World's Fair grounds. With eight stations, all in operation simultaneously, some sending messages only a few hundred yards and others to Chicago and Springfield, conclusive tests can be made under adverse conditions. The interference to which the stations in the Electricity Building are subjected from high-tension machinery of all descrip-

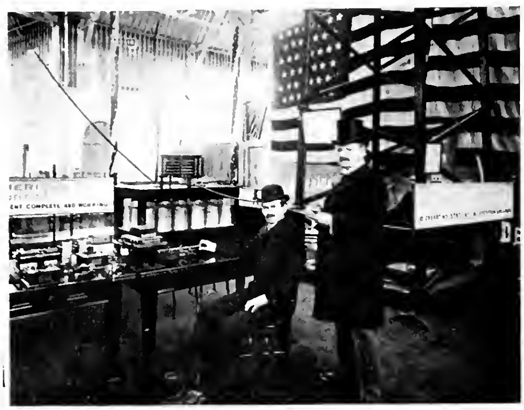

FIG. 14.—DE FOREST WIRELESS TELEGRAPH EXHIBIT.

The governor and pilot valve are operated by a worm gearing on the main shaft, shown in Fig. 5. The pilot valve has no "inertia of rest," and does not stick. On the larger machines a speed limit governor is arranged to instantly shut off the steam supply whenever a predetermined limit of speed above normal is reached.

Oil for the turbine and generator bearings is raised by a small plunger pump, Fig. 7, from a main reservoir in the bed plate and

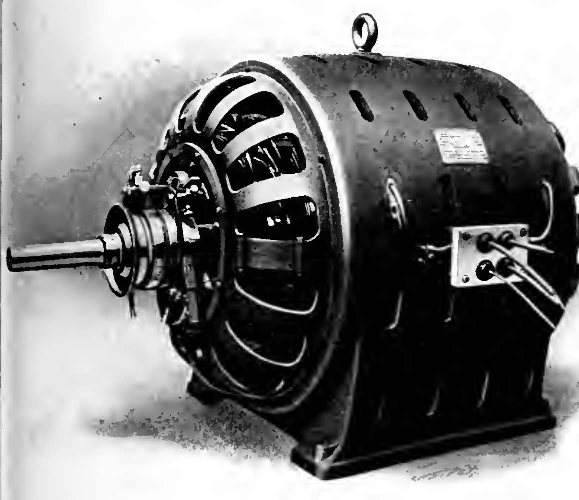

FIG. 8.—400-KW ALTERNATING-CURRENT TURBO-GENERATOR.

circulates by gravity, being cooled by water coils. No oil under high pressure is used in this type of turbine.

For the generators, two frequencies are now standard: 25 cycles per second for railway and power work and 60 cycles per second for lighting. The generator characteristics determine the speed of the turbine units; for instance, the 25-cycle generator which at 1,500 r.p.m. has two poles, has four poles at 750 r.p.m. Fig. 8 shows a generator of 400-kw capacity.

The turbine generator has a revolving field, small in diameter and finished smooth to minimize windage. Ventilation is secured by ducts cut in the solid steel. The standard construction of laminated armature is employed and the structure is well ventilated by air ducts between the laminations, communicating with the exterior through openings in the frame. Bar, strap or wire windings are used according to the voltage and capacity of the machine, and through protection afforded by embedding them in closed slots in the laminations.

The Frost Storage Battery Grid.

On April 12 last there was granted to Mr. George W. Frost, of Columbus, Ohio, a patent on a storage battery grid which merits special attention on account of the unusual design. The accompanying illustration, Fig. 1, will serve in a way to convey the idea embodied in the construction. The cut shows a section of the plate with one side sawed away, in order that the cross-section may be made clear. It would seem that it is practically impossible for the paste or active material to wear away or be forced out of a grid of a type similar to that in the illustration, as the T-shaped cross-section securely holds the paste in place. The paste is forced in while in a plastic condition and afterwards properly hardened and formed.

The grid is cast all in one piece in a two-part metal mould. The retaining strips are cast as thin as practicable, the usual thickness being .06 of an inch. This thickness is greater than is required to give the grid the necessary rigidity, and the cast grids are, therefore, passed under a broad milling cutter, which removes .03 of an inch from each side of the plate. The thickness of the cast grid, which is usually .32 of an inch for heavy stationary cells, is thereby re-

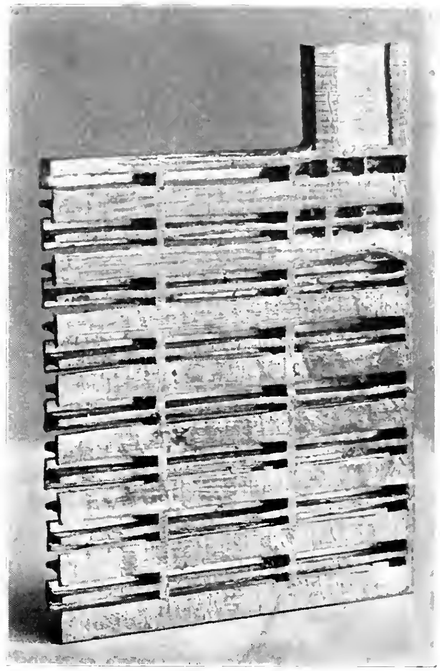

FIG. 1.—BATTERY GRID.

duced to .26 of an inch, the weight of the grid being decreased about one-third. For automobile batteries the grids are cast .25 of an inch thick and milled down to .19 of an inch. As the milling cutter passes over the surface of the plate it leaves narrow burrs or flanges at the edges of the retaining strips and webs. These flanges are of service in retaining the active material in the grid.

All grids are stiffened by several vertical ribs extending from the top to the bottom of the plate. The distribution of the metal of the grid is such as to give it great rigidity, with the least possible weight. The space available for active material amounts to from 50 to 70 per cent. of the total volume of the electrode, and the weight of active material, in portable batteries, may be 50 per cent. of the total weight of the electrode. The exposed surface of the active material is reduced to a minimum of about 40 per cent. of the total surface of the electrode, and the lead surface of the grid increases greatly the capacity of the plate as it becomes oxidized during use.

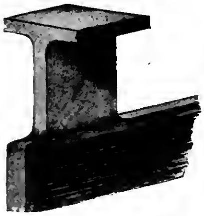

FIG. 2.—PLATE HEAD.

Careful tests have shown that the exposed surface of the active material is sufficient to give ready access to the electrolyte. For example, two cells were placed in series; one of them of 120 amp.-hours capacity of an approved standard design, the other of a similar capacity, but having plates of the design illustrated. A charging current was passed through them so that they received a total of 100 amp.-hours, or, in other words, they were purposely not quite completely charged. The standard type of cell was allowed to discharge its current through a fixed resistance, the output being 86 amp.-hours. Immediately thereafter the new type cell was made to discharge its current through the same resistance, the output being 87 amp.-hours, thus proving that the construction is such that the current is readily absorbed and given out.

The retaining strips and webs not only prevent the plate from buckling, but give a large contact surface, so that current is readily carried to or taken from the active material. The design of the grid is also such that it expands very evenly as the active material increases in volume. The grid can be cast in a simple and inexpensive mould and a workman can cast several hundred medium-sized grids in a day.

Fig. 2 illustrates a T-shaped head, which is cast integral with the plates, and Fig. 3 shows how the plates are lined up ready to

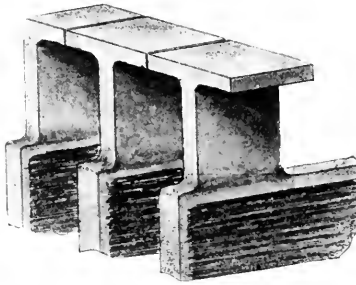

FIG. 3.—PLATES LINED UP.

be burned together with an oxyhydrogen flame; a mould being placed around the joint and the lead melted all the way through so as to produce an absolutely perfect joint.

The Frost grid has been adopted by the Columbus, O., Storage Battery Company as their standard for plate construction, and they have already installed several large lighting plant batteries, with plates of the new design.

Indiana State Independent Telephone Convention.

The annual meeting of the Indiana Independent Mutual Telephone Association will be held in the City of Lafayette, Ind., June 28 and 29. There will be able papers prepared and discussions upon topics of vital interest to all independent telephone people. The leading manufacturers and supply men will make creditable displays of all lines of goods. The headquarters will be at the Hotel Lahr. There will be a programme of entertainment such as trolley rides, vaudeville shows, music, an inspection of the electrical and mechanical department of Purdue University, banquet and a dance, all of which will be free gratis to the members attending the telephone association. The Sterling Electric Company, of Lafayette, have also sent out a warm open-handed welcome.

Theatre Dimmers.

It is a far cry from the earliest theatre dimmer consisting of incandescent lamps or iron wire mounted on a wood frame with crude circuit arrangements, to the thoroughly organized apparatus of today with their refinement of electrical design and excellence of me-

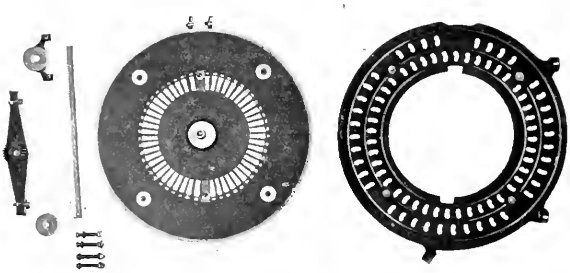

FIG. 1.—DETAILS OF DIMMER.

chanical execution. This is well illustrated in a new type of dimmer being placed upon the market by the Cutler-Hammer Manufacturing Company, several illustrations of which are given herewith. This new type is designed to meet the best requirements of stage lighting, which involve subdividing the lamps into a comparatively large number of circuits, thereby assuring more perfect control of the lighting and enabling special effects to be better obtained. In the dimmer illustrated, known as the "Simplicity" type, each unit or plate has a maximum capacity for 50 16-cp lamps, which number most nearly meets the average conditions for good stage lighting effects. As will be noted from the illustration, the dimmer units consist of circular plates mounted on an open frame, to which they are fastened by screws passing through three lugs into wrought-iron connecting bars. One of the features of this new type is the ease

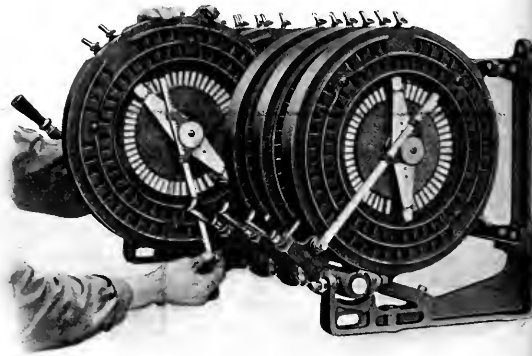

FIG 2.—THEATRE DIMMER.

with which a section may be removed, which operation is indicated in Fig. 2. It is merely necessary to remove a pin from the operating lever and the three screws above mentioned, when the plate can be lifted out. The several plates consist of a base of insulating material carrying the contact parts, as shown in Fig. 2, and all current-carrying parts essential to the operation of the dimmer, including lever contacts, resistance and binding posts, are mounted on this one insulating base and form a complete rheostat in themselves. The plate is enclosed by the gridiron casting shown in the illustration, this simply forming a cover and finish and carrying the lugs whereby the plate is secured to the frame. The several levers connected with the rheostat rack arm are loose on an interlocking shaft and may be moved without reference to the position of the master lever. A slotted cam, Fig. 3, is placed at the side of the lever and fixed to the shaft with set screws so as to be moved when the shaft is moved. This cam is provided with a slot into which the interlocking bolt drops, and is so arranged that if dropped when the slot is not directly below, the bolt will rest on the curved surface of the cam and drop into the slot when the cam is moved into the proper posi-

FIG. 3.—DETAILS OF LEVER.

tion. By this arrangement a dimmer plate may be set at any desired point independent of the master lever, and may be picked up by the master lever when it reaches the corresponding position. The dimmers may have the operating handles mounted on the frame, as in Fig. 1, or mounted on a board in front, the dimmer being provided with rack extensions sufficiently long to pass through the board and be attached to the operating levers.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—Exceeding dullness prevailed in the market, which was entirely professional, the interest shown by the public being confined to the purchase of bonds. The United States Steel stocks were weak on the dissolution of the conversion syndicate and adverse trade reports, but their decline was checked on short covering. There also seemed to be nervousness on the part of the bears in the standard railroad stocks, owing to easy conditions in money and the attending lack of liquidation. Among the industrials, apart from the decline in Steel common and preferred and in the 5 per cent. bonds, there was little worthy of note. United States Rubber attracted some attention on account of the firmness of both the common and the preferred, following the resumption of dividends on the latter. A heavy tone prevailed in General Electric, due to threatened competition in the electrical manufacturing business. This stock closed at 158. Allis-Chalmers common was steady throughout the week, closing at 6½, which is unchanged from the previous quotation. Preferred stock closed at 41, which is a net gain of 2 points. Westinghouse common lost 3 points net, closing at 155, and preferred closed at 175, which is the same as the previous quotation. Bell Telephone remains practically unchanged, closing at 126; and the same applies to Western Union, which closed at 88⅞. Commercial Cable closed at 175. Among the tractions Brooklyn Rapid Transit was quite steady, closing at 45½, while Metropolitan Street Railway was somewhat weaker, closing at 108⅝, being a net loss of 1 point. Following are the closing quotations of March 10.

CONSOLIDATION OF ROCHESTER ELECTRICAL INTERESTS.—Official announcement of the plans of the merger of the Rochester Gas & Electric Company, the Rochester Railway Company and the Rochester Light & Power Company has been made. The name of the consolidated company is to be the Rochester Railway & Light Company and its capital stock will be $3,000,000 of preferred stock and $6,500,000 of common. The issue of the first consolidated mortgage 5 per cent. bonds not to exceed $16,000,000 will be authorized and used to retire the present funded debt of the Rochester Gas & Electric Company. Provision has been made for the sale of $500,000 of these bonds at par, an accrued interest balance to be reserved for the requirements of the consolidated company. Under the provision of the consolidation a balance of about $1,200,000 in cash will be immediately available for the company's purposes, and from further assessments on the common stock and from surplus earnings it is estimated that another $1,000,000 will be forthcoming for betterments, extensions and improvements during the years 1904, 1905 and 1906. In addition to this amount, there will be in the hands of the trustee $4,073,000 of bonds reserved for future requirements.

THE MACKAY COMPANIES.—A director of the Mackay Companies makes the following statement to the *Wall Street Journal* of the amount of the stocks of the companies now held in Canada: "While five years ago fully one-half of the stock of the present Mackay Companies was held in Canada, at the present time not more than one-third of the stock at the very most is held here. It is held by between 400 and 500 people living in different parts of Canada, all the way from the Atlantic to the Pacific. Unlike most stocks, it is nearly all held for investment and I do not think there are 500 shares held by Canadians that could be secured in the open market. We are all satisfied with the plan that is being carried out by President Mackay."

SAN FRANCISCO TROLLEYS.—The United Railroads of San Francisco reports as follows for the year ended December 31:

	1903.	1902.	1901.
Gross	$6,243,219	$5,533,904	$5,125,883
Expenses and taxes	3,910,835	3,274,129	3,059,958
Net	$2,332,384	$2,259,775	$2,065,925
Other income	24,754	28,906	17,230
Total income	$2,357,138	$2,288,681	$2,083,155
Charges	1,536,438	1,324,050	723,200
Balance	$820,700	$964,631	$1,359,955
Sinking funds	123,999	114,000	84,000
Balance	$696,701	$850,631	$1,275,955
Dividends	480,000		
Surplus for year	$216,701		

An allowance of $157,500 for depreciation leaves $59,201 for profit and loss surplus.

CINCINNATI GAS AND ELECTRIC.—The earnings of the Cincinnati Gas & Electric Company for the year were $1,397,000 net, or 4.80 per cent. on the total capital, slightly over $29,000,000. It is expected that during the current year the earnings will aggregate $1,605,000, that for 1906 they will be $1,845,000, in 1907 $2,120,000, and in 1908 $2,436,000. The company now has 4,789 stockholders, against 4,300 last year. After deducting dividends of 4 per cent. for the year there is a surplus of $43,000.

INCREASE IN GENERAL ELECTRIC'S CAPITAL.—The stockholders of the General Electric Company, at a special meeting in Schenectady, on May 10, voted favorably on the proposition to increase the company's capital $3,325,500, making the total capital $48,325,500. Immediately after this meeting the annual meeting of the company was held, at which the present board of directors was re-elected.

Commercial Intelligence.

THE WEEK IN TRADE.—It is a pleasure to note the change in tone of trade reports as compared with the discouraging records of the past few weeks. The long-looked-for good weather has at last materialized, and agriculture and trade have taken on a seasonable aspect in consequence. Farmers are helped by it and crop preparations and planting have made good progress. Retail and wholesale trades, while improved, are not so strong as they should be, and the results are rather under the earlier expectations. Reorder trade with jobbers, as noted by one of the mercantile agencies, is slow and fall orders are backward. Other conditions, it is pointed out, partake of irregularity. Iron is quieter, and prices are weaker. On the other hand, the labor situation is more settled and favorable as compared with that of last year at this season. Pig iron is easy in price in all markets, with limited sales, aside from the placing of contracts for castings for new railway construction work. Finished products are dull and unsettled. Copper also tends downward on enlarged production and less eager demand. Business was on a very limited scale, and the export movement was much below the level of earlier months. The market closed steady but dull at the following prices: Lake, ⅜c. to 13⅝c.; electrolytic, 13⅛c. to 13¼c.; casting stock, 12⅞c. to 13⅛c. The exports of copper for April aggregated 13,567 tons, this being a heavy falling off as compared with previous months of the year. Railway earnings continue to decline. Failures, *Bradstreet's* states, are slightly above the normal in number, but, swelled by suspensions of financial institutions and a few large manufacturers, liabilities are heavy for this season of the year. The number of failures reported by the same authority, for the week ending May 5, was 176, against 188 the previous week and 175 the corresponding week last year.

SOME C. & C. ORDERS.—The C. & C. Electric Company, 143 Liberty Street, New York, has secured a contract for a 150-kw generator, together with six motors aggregating 200 hp for installation in large saw mills operated by A. A. Low, of Brooklyn, brother of Seth Low, in St. Lawrence County, Adirondacks. The plant will be operated by water. The Aetna (Ind.) Powder Company, whose plant is already equipped with 220 kw of C. & C. generators, has just ordered 75 hp of motors. The Arkelyan Press, Boston, Mass., has ordered a 30-hp series-parallel equipment to be utilized to operate a Hoe magazine press and a 35-hp outfit is to be shipped to the Seattle (Wash.) *Post-Intelligencer* for driving a Hoe quadruple press. The latter order is a duplicate of one secured three years ago. Another repeat order comes from the Ohio Quarries Company for two 50-hp motors to be used for operating grindstone lathes at the North Amherst quarries of the company. The St. Paul Roofing & Cornice Company, of Baltimore, is to be shipped four small motors for driving machine tools. Two 50-kw generators have been ordered by John R. Sheehan & Co., the building contractors, for the Gouverneur Hospital, to be used for lighting purposes. The engineering firm of Reis & O'Donovan, 15 Cortlandt Street, has ordered a 20-kw direct-connected generator and five motors aggregating 50 hp for operating equipment in the Manual Training High School. The St. Charles (Ill.) Home for Boys is to have two C. & C. direct-connected generators of 50-kw capacity each. This equipment will be used for both light and power. The C. & C. people also report receipt of a fair number of small orders for motors and generators for export to Canada, Cuba and Mexico.

GERMAN TELEPHONE SYSTEM.—Mr. Richard Guenther, United States Consul-General at Frankfort, Germany, states that the total cost of the German federal telephone system, operated in connection with the German federal telegraph system, is $60,000,000 up to date. The kingdoms of Bavaria and Württemberg are not included, these having their own independent telephone systems. The longest telephone connection in Germany is the one between Berlin and Paris, 742 miles. Next is Berlin and Budapest, 612 miles; Berlin and Memel, 593 miles; Berlin and Basel, 577 miles. The following connections are all more than 300 miles long: Berlin with Dortmund, Düsseldorf, Essen, Frankfort, Gleiwitz, Cologne, Königsberg, Munich and Vienna; Hamburg with Copenhagen; Frankfort with Paris and Hamburg. The line between Berlin and Frankfort is the most used—485 communications daily. The number between Berlin and Cologne is 243; Berlin and Vienna, 118, and Berlin and Düsseldorf, 116. In spite of the high fee not less than 65 communications daily take place between Berlin and Paris.

MANUFACTURING IN IOWA.—The Black Hawk Electric Company is the latest addition to the business concerns incorporated at Davenport, Iowa. The articles of incorporation show the new company to be composed of W. A. Fuller, James E. Bayliss and John H. Eagal. Mr. Fuller is the well-known electrician at the Rock Island arsenal and Messrs. Bayliss and Eagal have been in partnership for some time in Davenport in the automobile business. Mr. Fuller was originally with the General Electric Company for many years. The capital stock of the new company is $10,000 and the general nature of its business is to manufacture, contract and install electrical power and lighting plants, the sale, manufacture and installation of all electrical appliances, apparatus and sundries, mechanical, electrical and hydraulic engineering, and the selling, repairing and renting of automobiles. The officers and directors of the company are as follows: President, W. A. Fuller; vice-president, James E. Bayliss; secretary and treasurer, John H. Eagal.

THE GREGORY ELECTRIC COMPANY, of Chicago, reports among recent orders the sale of a direct-connected, 75-kw, two-phase, 60-cycle Westinghouse alternating generator to W. A. McKay & Co., Sydney, C. B., Canada; two 120-kw Westinghouse alternators to the Fulton Electric Light & Power Company, Fulton, Ky.; a 120-kw General Electric alternator to the Stanberry Electric Light & Power Company, Stanberry, Mo.; a 37½-kw Fort Wayne alternator to the Madeline Electric Company, Madeline, Cal., besides a large number of direct-current generators and motors. Their spring business is exceptionally good, sales being slightly in advance for the corresponding time of last year. The Gregory Company reports an unusual amount of repair work on hand at the present time in its repair department. The force in this department is now larger than ever before in the history of this company.

TURBINES FOR BRIDGEPORT FACTORY.—The Eaton, Cole & Burnham Works at Bridgeport, Conn., are to be operated by an electric plant, which will be one of the most elaborate and extensive equipments ever installed by an Eastern manufacturing concern. The electrical machinery will ultimately be capable of generating 2,400 kw. Westinghouse turbines will be put in while both the Westinghouse and General Electric Companies have secured orders for motors. The turbines, two of which have already been contracted for, will be 400 kw each. The motors, aggregating over 600 hp and ranging from 3½ hp to 30 hp, will be built by the General Electric and Westinghouse people—about 300 hp each. The switchboard, consisting of a combined generator, exciter and thirteen feeder panels, will be of Westinghouse build. G. K. Hooper, Bowling Green Building, is consulting engineer in the matter.

ELECTRICITY FOR COTTON SEED OIL PLANT.—The Stilwell-Bierce & Smith-Vaile Company, of Dayton, Ohio, has secured a contract for the first electrical equipment to be used in this country for operating a cotton seed oil mill. The mill will be built at Sinclair, La., for George H. Laws, of Cincinnati, Ohio, and will have a capacity of 60 tons per day. It will be driven by six motors aggregating 305 hp and varying from 5 hp to 75 hp. There will be two of 75 hp, three of 50 hp and one of 5 hp. The motors will be General Electric alternating-current, three-phase, 60-cycle, 550-volt type.

EQUIPMENT FOR NEW TIFFANY STORE.—The new $1,000,000 Tiffany Building, at Thirty-seventh Street and Fifth Avenue, New York City, is to be equipped with a 275-kw electric plant. There will be three units. The engines will be built by the Ames Iron Works, of Oswego, N. Y. The generators will be Westinghouse. The wiring will be done by Livingston Johnston, Jr., & Co., 113 East Twenty-second Street. The H. Krantz Manufacturing Company, of Brooklyn, took the order for the switchboard. C. O. Mailloux, 76 William Street, is the consulting engineer on the electrical work.

MOTORS FOR COAST FORTIFICATIONS.—The U. S. war department has placed a contract with the Holtzer-Cabot Electric Company, of Brookline, Mass., for a large lot of special motors to be used for the manipulation of disappearing gun carriages in the various fortifications along the Atlantic coast. The machines will be multipolar motors. Sixty motors have already been ordered of 4 hp. capacity, each operating at 400 r.p.m.

EQUIPMENT FOR ABRAHAM & STRAUSS.—Additional lighting equipment is to be installed in the Abraham & Strauss department store, Brooklyn. The outfit will comprise a 400 kw direct-current generator to be direct connected to a 600 hp Corliss engine. Mr. C. O. Mailloux, 76 William Street, is the consulting engineer in the matter. The existing equipment is of 800 hp capacity and has been installed for several years.

ALBERGER CONDENSERS FOR PHILA. R. T. PLANT.—The Alberger Condenser Company, White Building, has secured the contract for the condensing equipment for the Philadelphia Rapid Transit Company's plant. Jet condensers of dry vacuum system with centrifugal circulating pumps and Corliss two-stage dry vacuum pumps capable to taking care of four 1500-kw Westinghouse turbo-generators, will be installed.

TWENTY-THIRD REGIMENT ARMORY CONTRACT.—The lowest bidders on the lighting equipment to be installed in the Twenty-third Regiment Armory, Brooklyn, are Peet, McAnerney & Powers, 225 Fourth Avenue, New York. The capacity will he 185 kw., two 75 kw., and one 35 kw. generators have been requisitioned for. Mackenzie, Quarrier & Ferguson are the consulting engineers.

EQUIPMENT FOR WANAMAKER PLANT.—The John A. Roebling's Sons Company, 117 Liberty Street, has obtained the contract for the wire to be installed in the huge new Wanamaker store, New York, whose electric plant, as stated in our last issue, will have a capacity of 1800 kw. and will have Westinghouse generators and Buckeye engines—six units. The Thompson-Starrett Company is letting the contract.

EQUIPMENT FOR MEXICAN MINES.—An American syndicate in which William M. McCord and Lucien M. Fairbanks, of Chicago, are largely concerned, will very shortly be in the market for electrical equipment intended to operate large mills on its Peregrino mines in the Guadalajara district, Mexico. The properties have been recently acquired by the syndicate from the Gonzales family.

CUTTER CIRCUIT-BREAKERS FOR BRITISH NAVY.—The Cutter Company, of Philadelphia, whose Mr. Scott is now on the other side regarding the matter, has just secured a substantial contract from the British Admiralty for circuit-breakers for navy use. The company has also been allotted a contract for large circuit-breakers by the Philadelphia Rapid Transit Company.

TELEGRAPH WIRE FOR NICARAGUA.—The American Steel & Wire Company has received a contract for wire to be used in the construction of several hundred miles of telegraph lines in Nicaragua. These lines will be built by the United States & Nicaragua Company, a $10,000,000 concern in which prominent Pittsburgers are chiefly interested.

ALLIS-CHALMERS-BULLOCK.—The Canadian businese of the Allis-Chalmers Company, which recently acquired the Bullock Electric Manufacturing Company, of Cincinnati, will herafter be conducted by a new organization bearing the name Allis-Chalmers-Bullock, Ltd. The works and principal offies of this important new Canadian company are in Montreal.

BIG EQUIPMENT FOR GRAPHIC ARTS BUILDING.—Considerable electrical equipment is to be installed in the Graphic Arts Building, to be built by the *Town Topics*. Walter Tubby, the architect, of 80 Fulton Street, has the matter in hand.

General News.

THE TELEPHONE.

FLORENCE, ALA.—The Bell Telephone Company will build a line from Florence to Bailey Springs. Five thousand dollars will be expended in improvements.

DUNCAN, ARIZ.—A new telephone line is to be constructed from this place to Guthrie. The line will connect at Guthrie with the Gila Valley Telephone Company's line which will give Duncan direct communication with the towns of Clifton and Morenci.

TEXARKANA, ARK.—The New Long Distance Telephone Company, of this city, has opened its line from this city to Honey Grove, Tex., a distance of 100 miles. It is stated that a line will be built from Texarkana to Little Rock.

SANTA ROSA, CAL.—The Mark West & Santa Rosa Telephone Company has been organized here with R. Peterson as president and J. M. Laughlin, as secretary.

MONROVIA, CAL.—The Monrovia Telephone & Telegraph Company's system has been sold to Boaz Duncan, W. W. Wollwine and Dr. West Hughes, of Los Angeles.

LOS ANGELES, CAL.—Sealed bids will be received until May 23 by C. G. Keyes, county clerk, for a franchise to construct and maintain for a period of 30 years telephone lines throughout the streets and highways of the County of Los Angeles. Conduits and pole line will be used.

SAN BERNARDINO, CAL.—The United States Long Distance Telephone Company has filed articles of incorporation with the county clerk. The principal place of business is Los Angeles and the capital stock is $3,000,000. The directors are C. A. Gates, A. F. Morlan, D. J. Maguire, et al.

TAYLORVILLE, ILL.—The Interstate Telephone Company has decided to establish an exchange here.

HARDIN, ILL.—The Calhoun Telephone Company has increased its capital stock from $15,000 to $25,000.

MILLSTADT, ILL.—Permission has been granted to the Millstadt Telephone Company to build and operate a telephone line in this village.

EVANSVILLE, ILL.—The Evansville Telephone Company has been incorporated with a capital stock of $2500. The incorporators are William Wolff, John V. Tummel and William R. Mathews.

CHICAGO, ILL.—The charter of the United Telegraph & Telephone Company has been filed with the county recorder. The capital stock of the company is $2500, and the names of the incorporators are Henry E. Weaver, G. Watson French, Henry L. Turner, Harry D. Critchfield and Harry Rubens.

ALEXANDRIA, IND.—The Central Union Telephone Company is arranging to install an entirely new system in this city.

LEISURE, IND.—The Leisure Telephone Company has been incorporated with a capital stock of $10,500. The directors are Arthur L. Hiatt, David T. Hutcherson, David S. Wasdwell, Frank Smith and William Steel.

MECHANICSVILLE, MD.—The Southern Maryland Telephone Company which was incorporated by the last legislature has been organized with the following officers: J. F. Coad, president; L. J. Canter, vice-president; J. B. Ballenger, secretary-treasurer; J. L. Sothoron, recording secretary. A line has already been built by the company between Mechanicsville and Charlotte.

CEDAR FALLS, IA.—The Ced r Falls Mutual Telephone Company has been incorporated.

PLYMOUTH, IA.—The Plymouth Telephone Company has been incorporated with a capital stock of $10,000.

CONESVILLE, IA.—The Conesville Telephone Company has been incorporated with a capital stock of $10,000.

SANBORN, IA.—The Floyd Valley Rural Telephone Company, of Sanborn, has been incorporated with a capital stock of $1000. The incorporators are N. S. Miller, P. H. Miller, Wm. Clarksen, George Dummett, J. H. Greet and J. J. Getting.

OLATHE, KAN.—The Olathe Citizens Telephone Company has been sold to Oscar Ayers, of Gardner, for $20,000. Mr. Ayers is also proprietor of the Gardner Telephone Company. The connections are to be made with the Home Telephone Company of Kansas City within the next 30 days.

FLEMINGSBURG, KY.—The Flemingsburg Telephone Company has increased its capital stock from $25,000 to $35,000.

BOSTON, MASS.—A bill before the Legislature to put telephone and telegraph corporations under the supervision of the Gas and Electric Light Commission of this state was defeated by a tie vote a few days ago, on the third reading.

QUINCY, MICH.—The Michigan State Telephone Company has ordered material for the construction of 115 miles of lines in Branch County.

BEAVER CREEK, MINN.—A local telephone company is projected in this place. Mr. O. M. Page is president.

WHITE BEAR, MINN.—The Twin City Telephone Company has been granted a franchise for an exchange in this place.

SHAKOPEE, MINN.—C. Kopp, C. T. Buchanon and G. H. Reis have been granted a franchise to construct and operate a telephone exchange here.

HOLUM, MINN.—The Sunberg & Brooten Telephone Company will build a two-wire line between the two points named, the distance being 25 miles.

CHAPMAN, NEB.—The Chapman Telephone Association of Chapman has been incorporated with a capital stock of $50,000. This will be an independent system.

TROY, N. Y.—The Cooperstown, Cherry Valley & Sharon Springs Telephone Company has increased its capital stock from $5000 to $10,000.

SYRACUSE, N. Y.—Mr. Frank M. Potter, Jr., general superintendent of the Syracuse Telephone Company, is inspecting the automatic telephone systems in use in some Western cities, and if he believes such a system is feasible for Syracuse it will be installed here.

MIDDLETOWN, N. Y.—The Hudson River Telephone Company has purchased a lot in this city on which it will erect an office building. The new exchange will be fire-proof and will be used exclusively by the company. It is the intention of the company to lay conduit throughout the principal streets and remove its overhead wires.

RAVENA, N. Y.—The Ravena & Medway Telephone Company has been incorporated with a capital stock of $5000. The directors are William C. Harden and Ernest Bilz, of Stanton Hill; Harry Thorne, New Baltimore; Clifton Bedell, Aquetuck; E. L. Haight, Arthur Hartt, Frederick C. Bush and Clarence E. Whitney, of Ravena; Harric McK. Curtis, Coxackie.

FLUSHING, N. Y.—The New York & New Jersey Telephone Company announces that hereafter its local subscribers will have an unlimited local service and that the toll rates for calls to New York, Brooklyn and Long Island City will probably be considerably reduced in the near future. This action on the part of the company is claimed to be the result of the agitation by the Flushing Association for lower rates.

SYRACUSE, N. Y.—One million dollars will be expended in the extension and improvement of the systems of the Central New York and the Empire State Telephone & Telegraph Companies. The bulk of the appropriation will be expended in the city of Syracuse and vicinity. A new five-story exchange building will be erected in this city at a cost of $200,000. The new switchboard which will cost $150,000 will have a capacity for 20,000 lines.

RALEIGH, N. C.—The Ivey Telephone & Telegraph Company, of Mars Hill and Marshall, Madison County, has been incorporated with a capital stock of $125,000.

MIDDLEBURG, PA.—The Snyder County Rural Telephone Company has been organized by the election of Alfred Schloch as president and J. M. Baker, secretary. This company has been organized to take the place of the United Telegraph & Telephone Company.

PORT ROYAL, TENN.—The Cumberland Telephone Company has established an exchange at Port Royal, Tenn.

CUERO, TEX.—A telephone line is being constructed between this place and Cheapside.

PRINCETON, TEX.—The Princeton Telephone Company has increased its capital from $25,000 to $240,000.

TAYLOR, TEX.—The Williamson County Telephone Company will enlarge its system and make other improvements.

ROCKFORD, WASH.—The Rockford Telephone Company has been organized by C. S. Shepard as president; G. Saunders, vice-president, and O. Sullivan, secretary. The company will build a line from Mt. Hope to Rockford.

GLIDDEN, WIS.—The Glidden Telephone Company will build several farm lines during the summer.

ELECTRIC LIGHT AND POWER.

SEWARD, ALASKA.—The Seward Electric Company has been incorporated by George E. Dickinson and George Sohus.

MENDOCINO, CAL.—The Mendocino Electric Light & Power Company has taken possession of the Mendocino Lighting Company's plant. Ths price paid for the old company's property was $15,000. The business has been re-organized, Mr. J. A. Grindle being elected president and Albert Brown, secretary.

SILVERTON, COL.—The town of Silverton contemplates building about two miles of new line for its electric light service and installing 25 series arc lamps.

WASHINGTON, D. C.—Bids will be received May 24 at the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., for furnishing at the navy yards at Mare Island, Cal., and Puget Sound, Wash., a quantity of arc lamps, carbons, incandescent lamps, electric fans and exhausters, conduit and fittings, transformer, etc. Address H. T. B. Harris, Paymaster General, U. S. N.

WOOD RIVER, IDA.—The Idaho Electric Light Company is contemplating the installation of new machinery at this place and will greatly increase its plant.

GREER, IDA.—High water washed away the dam and flume of the Lolo Creek Power Company recently, entailing a loss of $10,000. The dam and flume were built on Lolo Creek at a cost of $25,000. The plant furnished electricity for a lighting plant and mills at Nez Perce. The damage will be repaired as early as possible.

LITCHFIELD, ILL.—The United Gas & Electric Company has been incorporated with a capital stock of $100,000. The incorporators are David David, William F. La Force and Jacob J. Frey.

OTTAWA, ILL.—The property of the Marseilles Water & Light Company has passed into the control of W. D. Boyce. The new board of directors chose the following-named officers: W. D. Boyce president; Benjamin Boyce vice-president; Dwight Cook, treasurer, and L. H. Strawn, secretary.

INDIANAPOLIS, IND.—The Union Trust Company, of this city, has been appointed receiver for the Home Heating & Light Company on the petition of Knight & Jellison Company. The complaint charges that Home Company is wholly insolvent. The plant will be operated by the receivers.

FT. THOMAS, KY.—Bids are wanted May 31 for wiring buildings, furnishing and installing watt and voltmeters, transformers, arc lamps, and other electric fixtures; erecting necessary pole lines on the reservation, and furnishing necessary current for electric lighting at this post. Address Lieut.-Col. W. H. Miller, Ch. Q. M., Pullman Bldg., Chicago, Ill.

BATON ROUGE, LA.—The Capital Light & Power Company has been incorporated with a capital stock of $25,000. The names of the incorporators are C. H. Kretz, E. F. Wieck and Turner Buynum.

ANNAPOLIS, MD.—Bids will be received at the Navy Department, Washington, D. C., until May 21 for boilers, engines and dynamos at the U. S. Naval Academy, Annapolis. Address Chas. H. Darling, Assistant Secretary.

KALKASKA, MICH.—The Kalkaska Electric Light Plant, Saw & Planing Mill contemplates building a dam and installing a plant for the utilization of water power. It intends to change its present direct current system to alternating current.

ANN ARBOR, MICH.—The Michigan Milling Company has two water powers within five miles of Ann Arbor, which are likely to be utilized for electrical work in addition to the present water power plant of the company. Mr. N. J. Kyer is manager.

JANESVILLE, MINN.—The Council is considering plans for a system of water works and electric lighting, to cost $22,000.

MONTEVIDEO, MINN.—The Montevideo Electric Light & Power Company, of Montevideo, has been incorporated; capital, $60,000. Incorporators: E. H. Sorlien and Olaus Lende, Granite Falls; E. A. Aspines and Lyndon A. Smith, Montevideo.

GREENWOOD, MISS.—The citizens of Greenwood have voted to issue $125,000 worth of bonds in order to purchase the electric light plant, water works and sewerage plant.

WOODVILLE, MISS.—Bids will be received by the Mayor and the Board of Aldermen until June 7 for building a system of water works and an electric light plant. W. C. Miller is mayor; C. N. Jenks, Fayette, Miss., is the engineer.

ST. LOUIS, MO.—A $1,000,000 mortgage on the property of the West St. Louis Water, Light & Power Company in favor of the St. Louis Union Trust Company, trustee, was filed in the Recorder's office in Clayton, St. Louis County, April 20. One thousand $1000 20-year gold bonds are to be issued, 600 of which are to be placed on the market immediately.

JOPLIN, MO.—W. G. Sergeant, of Joplin, has begun the work of building a dam across Spring River, at Lowell, Kan. It is estimated that a 7200-hp will be available. An electric plant will be erected on the banks of the river, and power will be transmitted to all sections of the mining district. It will probably be a year before the plant is in operation.

ST. LOUIS, MO.—Plans for a municipal plant to light by electricity that portion of the city south of Keokuk Street are still being considered by the Board of Public Improvements. It was first planned to locate a plant on the river near Elwood Street, but the latest idea is to have it situated at the House of Refuge, Osage Street and Virginia Avenue. The board has not yet progressed far enough to state what the plant will cost. At present the city pays $59,000 per year for lighting the city south of Keokuk Street with gas.

LINCOLN, NEB.—The North Platte Electric Light & Power Company, of Colorado, has decided to do business in Nebraska. Articles of incorporation have been filed with the Secretary of State of Nebraska. The principal place of business is in Denver, and the capital stock is $20,000. The company operates its plants by power obtained from North Platte River.

MUNNSVILLE, N. Y.—The Stanley Electric Company and the Cramp's have completed estimates for the construction of a power plant of 1000-hp at Limekiln Falls, near Munnsville, at a total estimated cost of $45,000.

NEW YORK, N. Y.—The following are the bids opened April 23 by the Bureau of Yards and Docks, Navy Department, Washington, D. C., for a turbo alternator, five induction motors, a generator and two switchboards and accessories: General Electric Co., $47,447 (with certain modifications); Westinghouse, Church, Kerr & Co., New York, N. Y., $54,000.

SALISBURY, N. C.—All the stock and securities, amounting to $50,000, belonging to the Salisbury Gas & Electric Light Company, have been transferred at par value to the Salisbury & Spencer Street Railway Company. H. B. McCanless is president, and H. Vanderford, secretary.

ANTELOPE, ORE.—The citizens are considering the question of constructing an electric light plant.

PORTLAND, ORE.—It is reported that the Portland General Electric Company will expend about $250,000 on an extension to its power plant.

BRADFORD, OHIO.—The Bradford Electric Light Company has been incorporated with a capital of $10,000 by A. W. McCune, G. Z. Arnold and others.

NEWTON FALLS, OHIO.—Bids will be received May 20 by the City Council for an electric light plant. The successful bidder will be given a contract for 10 years for lighting the village and a 20-year franchise for commercial lighting and furnishing power.

SHENANDOAH, PA.—Bids are wanted by the Borough Council for furnishing 60 or more street arc lights of 2000-cp.

CARBONDALE, PA.—The Hendrick Light & Power Company, of Carbondale, has been incorporated with a capital of $5000.

SPANGLER, PA.—The Spangler Electric Light, Heat & Power Company, of Spangler, has been incorporated, with a capital of $5000.

DANVILLE, PA.—The Council has voted to establish a municipal light plant and the Committee on Light has been instructed to procure estimates prior to asking for bids. H. B. Patton is borough secretary.

ANDERSON, S. C.—A company has been organized at Anderson, S. C., to develop the Hatton Shoals on the Tugaloo River. A large electric power plant will be built.

CALDWELL, TEX.—Cypher Bros., of Austin, propose constructing an electric light and ice plant here to cost about $10,000. D. A. Cypher is the engineer.

LEONARD, TEX.—The Leonard Electric Light & Ice Company has been organized to construct an electric light and ice plant. Y. T. Manning is president, L. H. Saunders, secretary.

CLARENDON, TEX.—The City Council has granted two franchises for the operation of electric light plants in Clarendon—one to Chase & Co., who have been for some time operating a plant in this city, while the other was granted to Jas. Trent, who will immediately install a plant.

HOUSTON, TEX.—The Houston Light & Power Company has been increasing the capacity of its plant and it is now ready for the installation of the machinery. The equipment includes three 450-hp Babcock & Wilcox boilers, General Electric generators and turbine engines. The distribution plant will also be extended.

WEST POINT, VA.—Broaddus & Byers, of West Point, are the engineers for an electric light plant for West Point.

WOODSTOCK, VA.—The Woodstock Electric Light & Power Company has been incorporated with a capital of $2000 to $10,000.

MARTINSVILLE, VA.—The Town Trustees have secured an option on the water power of Smith River, about 1½ miles south of Martinsville, and have employed A. L. Scott, representing Lockwood & Green, of Boston, Mass., to make a survey and estimate the cost of bringing this power to the town by electric transmission. The probable cost of the plant is $70,000.

WALLA WALLA, WASH.—A $250,000 mortgage has been filed by the Baker Loan & Investment Company of this city against the electric light plants, water rights, rights of way and other property of the Washington & Oregon Power Company, which is building a large plant on the South Fork of the Walla Walla River to supply power, etc., to Walla Walla, Wash. and Pendleton, Ore. The Washington & Oregon Company has also purchased the local plant at both Walla Walla and Pendleton.

MENOMONEE FALLS, WIS.—This city is reported interested in the construction of an electric light plant.

BURLINGTON, WIS.—An election will probably soon be held to vote on issuing $27,000 bonds for an electric light plant.

ANTIGO, WIS.—The station of the Antigo Electric Light & Power Company was destroyed by a fire of unknown origin on May 5. The loss on machinery is estimated at $20,000, but the indirect loss will be large, as the city is without light, and many small factories are compelled to shut down for lack of power All the local newspapers were also put out of business temporarily for the same reason.

OTTAWA, ONT.—It is reported that the Consumers' Electric Company will expend $30,000 in laying conduits from Chaudiere to its power station on Maria Street.

ST. CATHERINES, ONT.—The Lincoln Electric Light & Power Company of this place will install a 300-kw generator and will build a three-phase line to the power house of the Hamilton Cataract Power, Light & Traction Company for the lighting of the new Welland Canal.

THE ELECTRIC RAILWAY.

BIRMINGHAM, ALA.—The survey of the proposed electric railway from Bessemer to Blue Creek is finished. As soon as the report of the engineers has been accepted a company will be formally organized by the subscribers and work begun.

SAN FRANCISCO, CAL.—The Ione & Eastern Railroad Company (Electric) has been incorporated. The directors and stockholders are Jackson Dennis, of Amador County, and J. J. Fagan, William Pardy, R. E. Wallace, H. H. Ferns and S. C. Sheeline, of San Francisco. The capital stock is $1,000,000.

DENVER, COL.—The Northern Colorado Electric Railway Company has filed its articles of incorporation with the Secretary of State at Denver. The principal offices will be located at Fort Collins. The main line will run from Fort Collins to Denver. Branch lines are planned between Fort Collins, Eaton and Greeley and Fort Collings, Chambers' Lake, Walden and thence to the Grand River in Grand County. The capitalization is $1,000,000. The directorate is composed of P. J. McHugh, L. C. Moore, R. L. McCullogh, H. A. Edmonds and W. A. Mosman.

MERIDEN, CONN.—The transformer plant which the Meriden Electric Railroad Company has been erecting at Hanover Park has been completed. Under the new arrangement the power to operate the local electric railway will be transmitted from the New York, New Haven & Hartford Railroad Company's station at Berlin, a distance of 9 miles. The old power plant on Pratt Street will be kept in readiness for use in cases of emergency.

MT. VERNON, ILL.—The Southern Illinois Electric Railway Company, which has in contemplation the construction of an extensive system of electric railways in this territory, has voted to increase its capital stock from $50,000 to $2,000,000.

ALTON, ILL.—The Alton Light & Traction Company has awarded the contract for building an embankment for its electric railway from Alton to East Alton, and may continue to build the line into St. Louis, independent of the St. Louis syndicate.

MT. VERNON, ILL.—The Traction, Engineering and Construction Company has been incorporated, with a capital stock of $2500, by John R. Piercy, Isaac A. Smith, Fred. L. Webster, E. C. Parker and William C. Blair. The same interests are connected with the Southern Illinois Electric Railway, and the inference is that the Traction, Engineering & Construction Company will build the Southern Illinois Company's lines.

JEFFERSONVILLE, IND.—The Jeffersonville City Railway Company has been purchased by Peter Arundel, representing Louisville capital, and is now being equipped with electricity. The road extends from Jeffersonville to Port Fulton.

KOKOMO, IND.—The Kokomo, Marion & Western Traction Company is building a new power plant with a capacity of 800-kw, all units being direct-connected. The cost of the plant will be $50,000 and the new equipment will be ready for operation July 1 next.

MUNCIE, IND.—A franchise has been granted the Oil Belt Traction Company through the northern portion of Delaware County. It is proposed to build from Alexandria through the northern part of the country to Celina, Ohio. A branch will be extended from Gaston to Muncie.

BOSTON, MASS.—The Railroad Commissioners have authorized the Boston & Worcester Street Railway Company to issue $100,000 additional capital stock at $100 per share; also $200,000 twenty-year 4½ per cent. bonds, the proceeds to be used to pay off floating debt incurred in constructing and equipping the road.

JACKSON, MICH.—Articles of incorporation of the Consolidated Traction Company, of Jackson, have been filed with the Secretary of State. The new company is one formed by W. A. Bowland to take over the property of the Jackson & Suburban Traction Company, now operating the Jackson City lines and a road to Grass Lake, and also a spur line connecting Wolf Lake resort and casino, 10 miles east of Jackson, with the Roland system. The new company is at present independent of the Jackson & Battle Creek Traction Company, and also of the Jackson & Ann Arbor Company. The capital stock of the new company is $1,000,000.

ST. LOUIS, MO.—The St. Louis Elevated & Subway Railroad Company has applied to the City Council for the second time for a franchise to build and operate an elevated and underground railroad subway and tunnel for passenger service from Third Street and Washington Avenue to the city limits. H. K. Gilman, S. L. Langsdale, Harry S. Doyle and J. E. Longworth are interested.

ST. LOUIS, MO.—Further changes in the management of the St. Louis Transit Company, looking to a general reduction of operating expenses, are about to take place. General Manager Robert McCulloch has announced the resignations of W. O. Mundy, chief engineer, and Superintendent Dunne, of overhead construction, both to take effect on or about May 1. Their duties will be merged into those performed by other officers.

JERSEY CITY, N. J.—The North Jersey Street Railway Company has purchased a large tract of land on the Hackensack river front on which it will erect a large power plant. Power for the entire trolley system east of the Hackensack River will be supplied from this station. Architects are now at work on the plans and it is stated that the cost of the buildings and machinery will be at least $400,000.

CUBA, N. Y.—W. F. Mayo, of Cuba, and others, have recently been in conference here regarding the building of an electric railway from Cuba to Weston's Mills, a distance of about 16 miles.

NEW YORK, N. Y.—The proposal of the New York & Jersey Railroad Company to continue its Hudson River tunnel from the terminus of West Tenth and Hudson Streets, originally proposed, under Sixth Avenue and to Thirty-third Street, has been reported adversely by the committee that had the matter in charge.

ROCHESTER, N. Y.—At the annual meeting of the stockholders of the Albion Electric Railway Company the following directors were chosen: Charles B. Hill, E. C. Lufkin, C. L. Ingham, George H. Sickles and Frederick B. Griffith, Jr., of Buffalo; Alvah K. Potter and George E. Greene, of Lockport; Lorenzo Burrows and George B. Church, of Albion. The directors elected these officers: Charles B. Hill, of Buffalo, president; Frederick B. Griffith, Jr., of Buffalo, secretary and treasurer.

ROCHESTER, N. Y.—Senator Merten E. Lewis, attorney for the promoters, says the electric railway from Rochester to Caledonia is assured. The company will be incorporated in about two weeks. Plans and surveys have been completed. The road is to be known as the Rochester, Scottsville & Caledonia Railroad. The subscribers to the new company are: Henry C. Brewster, John F. Alden, Charles T. Chapin and Le Grand Brown, of Rochester; D. C. Becker, of Fairport; Andrew H. Brown, of Penfield; Charles H. Palmer, Eugene Brown, Selden S. Brown and Isaac W. Salyerds, of Scottsville. The company is to be capitalized at $250,000. Henry C. Brewster is to be president of the corporation.

COHOES, N. Y.—The Cohoes Railway Company has filed papers of incorporation with the Secretary of State. The capital is $120,000. The new company is a reorganization of the Cohoes City Railway, which was sold at auction recently. The directors are P. C. Dugan, John W. McNamara, president of the United Traction Company, of Albany; James McCredie, Edgar S. Fassett, Reuben C. Calkins, Eugene Crawford and Thomas Van Antwerp, of Albany; James N. Wallace, of New York, and John E. MacLean, of Cohoes. The stockholders have authorized the issue of the mortgage which is a part of the plan of reorganization. The United Traction Company interests are the controlling factor in the company.

NEW YORK, N. Y.—The Central Crosstown Railroad, which is controlled by the Metropolitan Street Railway Company, has sold to Kuhn, Loeb & Company $2,250,000 of two-year 5 per cent notes, secured by deposit of $2,250,000 guaranteed bonds of the Crosstown Company. The proceeds reimbursed the Metropolitan Securities Company for the money advanced in electrifying the crosstown system. Kuhn, Loeb & Company have also purchased $2,300,000 of the Metropolitan Street Railway refunding 4 per cent. bonds, the proceeds from which will be used in part to pay off the $1,500,000 Broadway & Seventh Avenue first 5s, maturing June 1, and the balance for other refunding operations. This increases the outstanding refunding 4s to $15,080,000. In addition, Kuhn, Loeb & Company have bought $2,000,000 of Third Avenue first consolidated 4s, increasing the outstanding issue to $37,000,000. The new bonds are issued to pay for improvements and other purposes.

CHARLOTTE, N. C.—The route has been surveyed for a trolley line connecting Roanoke, Va., and Mount Airy, N. C.

MARIETTA, OHIO.—The Parkersburg, Marietta & Interurban Railway Company is securing right of way for a line up the Muskingum River Valley to Devol.

DEFIANCE, OHIO.—The Ohio Northern Traction Company is making surveys for its line which is to extend from Defiance to Wauseon, O., and Adrian, Mich.

CAMBRIDGE, OHIO.—The Consolidated Company has filed an amendment to its charter changing its name to the Cambridge Power, Light & Traction Company.

COLUMBUS, OHIO.—The Chillicothe, Bainbridge & Aberdeen Electric Railway Company has been incorporated, with $50,000 capital stock. The incorporators are G. F. Horn, A. A. Luther, O. R. Eyler and Floyd E. Furneau.

INDIANA, PA.—The Indiana Street Railway Company and the Indiana & Blairsville Intersection Street Railway Company have been merged.

WASHINGTON, PA.—The Washington County Street Railway Company has been granted a franchise here. The plan of the company is to build an electric railway from Washington to Pittsburg.

BRADFORD, PA.—It is said that the Bradford Street Railway Company's property and franchise have been purchased by a party of Philadelphia capitalists, and that the Olean, Rock City & Bradford Company is included in the deal.

EASTON, PA.—The Easton Transit system and its allied roads in Easton and Phillipsburg, and the Easton, Palmer & Bethlehem road, now controlled by the Lehigh Valley Traction Company, are to revert to the Easton Consolidated Electric Company. H. R. Fehr is to assume control for the old company. The Lehigh Valley Traction Company has defaulted in the payment of the rentals of its leased lines, and the receivers have been unable to better conditions to any great extent.

CHATTANOOGA, TENN.—The Rapid Transit Company of Chattanooga will issue $250,000 in bonds for improvements and extensions of its consolidated lines.

BEAUMONT, TEX.—It is reported that a large part of the stock and bonds of the Beaumont Traction Company has passed into the hands of a Boston syndicate.

SALT LAKE CITY, UTAH.—Work on the Salt Lake Southern electric railway, which will traverse several miles of the suburbs of the city, has been resumed. The company has filed with the county clerk amended articles of incorporation, increasing the capital stock from $500,000 to $2,000,000, and the Knickerbocker Trust Company, of New York, has been designated as trustee. It was stated recently that $1,500,000 will be expended this year in construction work. A power plant with a capacity of 3500 horse-power is to be established by the company a few miles south of the city.

DANVILLE, VA.—The Danville Street Railway & Electric Company has asked the permission of the County Circuit Court to extend its line to Stokesland, 5 miles south of this city. The line will be extended this spring to the Country Club, beyond the suburbs.

WEST SEATTLE, WASH.—It has been voted to issue $18,000 worth of bonds by the city to build an electric street car line. The city is to own and operate the road.

EAU CLAIRE, WIS.—The Chippewa Valley Electric Railroad Company, of which Arthur E. Appleyard is president, has taken over all of the property of the Eau Claire Light & Power Company, including its franchise.

FOND DU LAC, WIS.—The Fond du Lac Northwestern Railway Company has increased its capital stock from $100,000 to $750,000. Work has been started on the Fond du Lac end of the road, and it is thought a branch will be built to this city, connecting with the Green Bay-Kaukauna interurban.

NEW WESTMINSTER, B. C.—W. Blackmore & Son, architects, have prepared plans for a sub-station to be built by the British Columbia Electric Railway Company.

NEW INDUSTRIAL COMPANIES.

THE CENTURY GAS & ELECTRIC FIXTURE COMPANY, of New York, has been incorporated with a capital stock of $3000. The directors are S. M. Israel, E. M. Pine and S. H. Shinnisky, New York.

THE WOOD CHANGING SIGN COMPANY, of New York, has been incorporated with a capital stock of $100,000. The directors are N. B. Wood and W. A. Kroyer, New York, and B. B. Austin, Brooklyn.

THE JOHNSON ELECTRICAL MANUFACTURING COMPANY, of Phoenix, Ariz., has been incorporated with a capital stock of $200,000. The incorporators are W. Frederick Nutt and Charles H. Johnston.

THE H. R. & K. MANUFACTURING COMPANY has been incorporated in New York to deal in electrical appliances. The capital stock is $75,000 and the directors are W. E. Knight, Fanwood, N. J., and H. C. Workman and M. A. Ryan, New York.

THE HUTCHISON WIRELESS TELEPHONE COMPANY has been incorporated at St. Louis with a capital stock of $3000. The incorporators are M. R. Hutchison, Hallon C. Spaulding, Edward C. Husted, L. Z. Harrison and Joseph A. Wright.

THE TAPE TRANSMITTER MANUFACTURING COMPANY has been incorporated in Jersey City, N. J., with a capital stock of $100,000. The incorporators are Edward T. Clarke, Jersey City, and Elihu Beach and Loyal Ward Reynolds, New York City.

THE ALLENTOWN ELECTRIC CONSTRUCTION & SUPPLY COMPANY has been incorporated at Allentown, Pa., with a capital stock of $30,000. The incorporators are U. H. and W. E. Wieand, W. H. Gangawere, R. E. Wright, J. R. Druckenmiller and W. H. Miller.

THE NEEL ARMSTRONG COMPANY has been organized at Portland, Me., for the purpose of manufacturing and dealing in electrical apparatus. The capital stock of the new concern is $200,000, of which nothing has been paid in. The officers are: President, Willard C. Baldwin; treasurer, Geo. C. Knight.

LEGAL.

WESTERN UNION VS. PENNSYLVANIA.—Judge Gray on May 2 handed down an opinion in the United States Court of Appeals at Philadelphia remanding the case of the Western Union Telegraph Company against the Pennsylvania Railroad Company to the Circuit Court for further proceedings. The litigation involves the right of way of the telegraph company along the lines of the Pennsylvania Railroad Company, and the United States courts in that district have always sustained the position of the railroad. The last decision, however, reverses the Circuit Court on a demurrer raised by the telegraph company and the case is sent back to the lower court for a hearing on its merits.

TO OUST CUMBERLAND TELEPHONE.—At Nashville, Tenn., on May 2, Chancellor Allison handed down a decision to-day ordering that the Cumberland Telephone & Telegraph Company, a Kentucky corporation, be ousted from the State. An appeal to the Tennessee Supreme Court was taken. The grounds for the decision are discrimination and conspiracy to stifle competition. A receiver was also asked for, but the court declined to appoint one, "for satisfactory reasons." One specific charge is that the leasing of the Maury County or Columbia Exchange to Leland Hume, an officer of the Cumberland Company, was an evasion of the law, and designed to permit rates to be illegally cut. It was also charged that the defendants had broken down independent concerns elsewhere by methods which they had no right to practice. Officials of the Cumberland Telephone and Telegraph Company decline to make any statement further than to assert that their business will continue to be transacted as usual. The company has an authorized capital of $20,000,000 and about $12,000,000 is outstanding.

OBITUARY.

MRS. MARY PECK, mother-in-law of Prof. Elihu Thomson, and Mr. E. F. Peck, manager of the Schenectady, N. Y., electric railway system, died last month at Lakewood, N. J. She was the daughter of the Rev. Dr. Emerson Davis, of Westfield, Mass., and widow of Mr. Charles Peck, of New Britain, Conn. She was a woman of strong religious convictions, active social sympathies and prominent in all kinds of philanthropic work. Her death at the Laurel House, Lakewood, was due to a slip and falling down a flight of stairs.

EDUCATIONAL.

HEBREW TECHNICAL INSTITUTE, New York City, will hold its commencement exercises on Wednesday evening, May 18, in the large hall of Cooper Union, preceded by an exhibit of work of the graduating class at the Institute, Stuyvesant Street.

ELECTRO-RADIO THERAPY.—The importance that radio-activity is assuming as an agent in the treatment of disease is emphasized in the establishment by the trustees and medical faculty of the New York Polyclinic Medical School and Hospital of a special department of electro-radio therapy.

PRATT INSTITUTE, Brooklyn, N. Y., in its March *Monthly* gives the annual report of the department of science and technology, including a very interesting illustrated description of the electrical laboratory and the methods adopted there of instruction in testing apparatus, cables, etc. The report is signed by Mr. S. Sumner Edwards, who is to be congratulated upon this useful report of good work done.

PERSONAL.

MR CLARENCE GEORGE has been appointed city electrician of Houston, Tex., by Mayor Jackson.

MR. WALTER H. GRAEFF, of G. & O. Braniff, Mexico City, which concern represents the Westinghouse interests in the Southern Republic, is now on a visit to the States.

CAPT. C. F. GOODRICH, U. S. N., has an interesting article in the latest (March) issue of the *Proc. U. S. Naval Institute* on "Cable Cutting." It is full of data with reference to this important topic.

MR. L. W. MILLER, secretary of the Goudey-McLean Company, 120 Liberty Street, New York, is expected back very shortly from Europe, where he has been for some two years past in connection with the company's business.

MR. J. J. O'BRIEN, who has been for some years past cashier of the Chicago Edison Company has resigned and has become general auditor for the H. M. Byllesby & Company, the consulting and contracting electrical engineers of Chicago and New York.

MR. J. L. LYLE, manager of the New York City offices of the Buffalo Forge Company, has been appointed secretary of the Engine Builders' Association, vice Mr. D. L. Fleming, of the Harrisburg (Pa.) Foundry & Machine Works, who has resigned from the position under pressure of business.

MR. J. W. STEED, of the International Steam Pump Company, will have charge of the installing of the electrical equipment, machine tools, etc., at the huge Worthington works now being hastened to completion at Harrison, N. J. Practically all the electrical equipment will be of General Electric manufacture.

MR. CHARLES H. LEDLIE, Rialto Building, St. Louis, was the consulting engineer of the Kansas City Telephone Company's plant described recently in these pages, the entire system including switchboards, desk equipment and telephones, as well as the outside construction work, having been built under specifications prepared by him, and the work done under his immediate supervision.

MR. H. V. CROLL, who has been in charge of the Salt Lake City, Utah, office of the Allis-Chalmers Company for several years, and who was before that the representative of the E. P. Allis Company at Spokane, Wash., has been appointed to the charge of the Allis-Chalmers office in San Francisco, as the successor of Mr. Geo. Ames, who has resigned. Mr. Croll's San Francisco office is 623 Hayward Bldg.

PROF. S. P. THOMPSON, F. R. S., is now busily engaged on the second volume of his new edition of "Dynamo Electrical Machinery," in which he is giving special care and attention to the subject of alternators. When it is off his hand, he intends making a final effort to complete the rewriting of that valuable work, "The Electro Magnet," now seven years in process of execution, to embrace a large amount of original matter.

CHARLES HENRY DAVIS & PARTNERS, of New York City, have issued an announcement of the dissolution of this firm from May 1, and the formation of Charles Henry Davis & Company, at 25 Broad Street, by that gentleman and Mr. Nat Tyler, Jr. As to the other old members, Mr. T. W. Sprague will practice at 4 State Street, Boston, Mr. John S. Griggs, Jr., 25 Broad Street, and Mr. J. Byers Holbrook, at the same address.

MR. C. P. BRUCH, assistant general manager of the Postal Telegraph Cable Company, is also president of the Canton Society of New York, composed of men who came from President McKinley's city. The society gave a dinner on May 7 to their fellow townsman, Justice Day of the U. S. Supreme Court, at which a number of distinguished public men were present. Mr. Bruch presided and also discharged the duties of toastmaster in a very felicitous manner.

MR. PAUL G. BURTON, formerly chief inspector of the Western Electric Telephone installation department, has been appointed superintendent of maintenance of the Chesapeake and Potomac Telephone Company, the territory of which includes Baltimore and Washington. Before his departure from New York Mr. Burton was the guest of honor at a dinner given at the Arena by the Western Electric Foremen's Club, of which he had been president for several years.

DR. LEE DE FOREST, whose wireless telegraph system is being used so effectively in the Russo-Japanese war by the *New York Times* and *London Times*, is the subject of an interesting biographical sketch in the former paper. It is accompanied by an engraving which shows him mounted as a bugler of the Yale battery in the Spanish war of 1898, when he was one of the first of the New Haven men to enlist. The following year Yale made him a Doctor of Philosophy for his thesis on Hertzian waves.

MR. IRVING A. TAYLOR, who has for many years been connected with the electrical industry both on the manufacturing side and as consulting engineer associated with A. B. Herrick, has joined the staff of the Engineering Company of America. Mr. Taylor has had a very broad experience in central station work, not only with Edison systems but also with high tension transmission plants, one of his recent tasks being the installation of the 12,000-volt generators at the power house of the Niagara Falls Hydraulic Power Company.

MR. T. A. EDISON.—A dispatch from Washington, May 10, states that President Roosevelt recently overruled a decision of Patent Commissioner Allen in a case in which Mr. Edison is interested, and directed that a hearing be given to Mr. Edison, which had been denied. It appears, from the dispatch, that Mr. Edison applied for a patent in connection with his storage battery, and that another inventor working along the same lines, it is alleged, was permitted to withdraw his application and insert in it the substance of Mr. Edison's claims. Mr. Edison protested and asked for a hearing, which the Commissioner refused to grant. President Roosevelt was appealed to with the above result.

MR. S. STERN, vice-president and managing director in Europe of the American Electrical & Novelty Company, returned recently from a trip abroad. The company now has factories and selling agencies in Paris, Berlin and London. "The Germans take most kindly to our ideas and to our goods," Mr. Stern said, "but they are also the best imitators. In July, 1900, I established our first factory in Berlin for the manufacture of portable electric lights. The Germans had never heard of such a thing, then, but inside of a year I had seventy-five competitors. We created a new industry in Germany, and to-day there are at least 150 factories there making electrical devices. The Germans take to all our novelties and are our best customers." Mr. F. J. Alvin, president of the company, has also recently made a quite successful trip through Canada.

MR. G. MARCONI left England last Saturday by the Campania for New York. The ship has been equipped with long distance wireless apparatus, and during the entire voyage Mr. Marconi expects to be able to keep in communication with both shores. He is accompanied by Mr. W. W. Bradfield, engineer of the American Marconi Company, who has been with him for several months past studying the new apparatus designed for the operation of the trans-Atlantic system. The first station to be equipped will be that at Glace Bay, Nova Scotia, following which the station at South Wellfleet will be put in shape. When the stations on this side of the Atlantic have been opened for business there will be stations abroad, to which communications may be directed, at Poldhu, Cornwell and Pisa, Italy. By means of relay from these stations wireless communication may also be had with Amsterdam, Holland; LaHague, France; Gibraltar; Rosslare, Ireland, and other points.

MR. HERMAN A. STRAUSS was appointed general manager of the Sheboygan Light, Power & Railway Company, of Sheboygan, Wis., early this year. This company operates about 30 miles of city and interurban trackage and all the lighting systems of the city of Sheboygan. This appointment of Mr. Strauss comes after one year's service as engineer of the Construction Company of America in the design and construction of ten miles of interurban railway and a large, modern, fire-proof power station for the Sheboygan Light, Power and Railway Company. Mr. Strauss has had a large and varied experience. He was attached to the engineering staff of the Westinghouse Electric and Manufacturing Company for several years; he has acted for two years as an assistant electrical engineer for the Manhattan Elevated Railway Company of New York City, throughout the period of electrification of this system, and has done considerable independent consulting engineering work.

MR. W. E. SHELDON, formerly treasurer of the Fitchburg Steam Engine Company, who was afterwards connected with the Providence Steam Engine

Company and with the Providence Engineering Works, has become connected with the "Manufacturers Agency," Milk & Oliver Streets, Boston, Mass., which has rented an entire floor of 35 rooms in the Oliver Building there. The agency will act as selling agent and purchasing agent for manufacturers, furnishing capital, loans and everything convenient for manufacturers having dealings with it. The proposition is to finance companies and represent them through New England, reaching out for business in a manner which a moderate manufacturer cannot do. A large staff of traveling salesmen has been engaged who know the companies in that territory thoroughly, and who are experts in respective lines. To Mr. Sheldon has been given the engineering department, of which he will have full charge. Mr. J. F. Preston is the president of the organization.

Trade Notes.

THE TOLEDO ELECTRIC STORAGE BATTERY COMPANY, Toledo, Ohio, capitalized at $100,000, has been re-organized with Mr. J. Grasser as president.

ELECTRIC POWER FOR BREWERY.—F. C. Werk, Cleveland, Ohio, has secured a contract for equipping the plant of the Isaac Leisy Brewing Company, of Cleveland, with electric power. A number of motors will be installed.

SPRAGUE ELECTRIC COMPANY has issued a bulletin devoted to its M. C. type motors, direct current, open form and enclosed form, intended for very general application. It is No. 216 and is well illustrated as well as full of detail data.

CUTLER-HAMMER IN WEST AUSTRALIA.—The Cutler-Hammer Manufacturing Company has appointed the West Australian engineering and contracting firm of Splatt, Wall & Co., Perth, as agents for the Cutler-Hammer specialties in that part of the world.

THE F. BISSELL COMPANY, Toledo, Ohio, has just issued a very neat little "Handbook of Switchboards." It is devoted to boards of 2500 amp. or less, complete or in parts, and is profusely illustrated by diagram as well as being carefully explicit as to details of every kind.

H. T. PAISTE COMPANY, Philadelphia, has issued some new calendar blotting pads for May, illustrating and describing its P. K. show window "fieldings," the P. K. Pushin attachment plug, etc. These specialties are thus attractively brought to notice.

THE PROVIDENCE ENGINEERING WORKS, of Providence, R. I., has established a New York office at 42 Broadway, N. Y., in charge of Mr. Wm. E. Hussey, who is well known in engine circles. The New York office will also cover the Philadelphia territory.

COLUMBIA INCANDESCENT LAMP COMPANY, of St. Louis, Mr. A. Garrison, president, has found it necessary to open an office in Minneapolis, and to carry a complete stock of lamps at that point in order to care properly for its large and growing number of customers in Minnesota and the Northwest. The business there has shown a remarkable increase. Mr. J. B. Coale, who formerly represented the company in the district named, will be in charge of the Minneapolis office.

INCREASE OF CAPITAL.—The directors of the Monarch Electric Manufacturing Company, of Warren, Ohio, have decided to increase the capital stock of the company from $10,000 to $50,000. The increasing business of the company requires larger capitalization in order that it may be more properly carried on. The outlook for the fall trade is stated to be very good and the plant will be operated throughout the summer so as to be able to meet the demand for the company's products.

MULTIPLE TAP CABLE SYSTEM.—Mr. L. W. Stanton, telephone engineer, Electric Building, Cleveland, has issued an interesting illustrated bulletin as to the merits of the "multiple tap" system for telephone services, as compared with older methods. This open-wireless or all-cable telephone method has been introduced with excellent results and is highly spoken of by experts and authorities. One view shows a single cable on pole at Austin, Minn., equal to a lead of five crossarms and 50 bare wires.

WARD-LEONARD ELECTRIC COMPANY, of Bronxville, N. Y., has just issued a new catalogue, No. 19,038, covering its enameled resistance units. On account of the increasing demand for new sizes of this resistance unit, it has catalogued three new sizes; one a tube 2 inches long and 7-16 inches diameter, upon which in extreme cases can be placed 5000 ohms resistance. Another is a tube four inches long by 7-16 inches diameter upon which can be placed 11,000 ohms. The SS type covers a tube suitable for small rheostats, as it is divided into eight steps. Copies of the bulletin can be had on application by any one interested.

GENERAL ELECTRIC COMPANY, through its power and mining department at Schenectady, N. Y., has just issued a very handsome and complete report dealing with the subject of electric mine haulage. It is a handsome, small quarto of 70 pages, profusely illustrated and gives also a great variety of interesting details and information, including several quoted articles, and considerable original data. It is the more valuable also because of the historical record presented; but probably its chief value lies in the impressive demonstration that it makes of the remarkable rapidity and extent of the adoption of electricity in mining operations all over the country.

THE MICA INSULATOR COMPANY, of 218 Water St., New York City, has incorporated the exhibit of its well-known specialty "Micanite," with that of the State of North Carolina, in the Mines and Metallurgy Building, St. Louis. The exhibit is an interesting object lesson showing to what utility and extent mica can be put in the ever-expanding field of electrical insulation. Micanite in all kinds of shapes and forms is shown, including flat sheets of various thicknesses, generator and motor commutator segments, and rings of many of the standard types; and Micanite tubes from one-eighth of an inch in diameter to the large tubes entering into the construction of induction coils for X-ray purposes.

ROSSITER, MACGOVERN & COMPANY, 71 Battery Place, New York City, have issued for May an elaborate bulletin of all the second-hand material which they now have ready for the market. The phrase "second-hand" is used advisedly as almost all of the material is of modern design and of standard manufacture; has been thoroughly overhauled in the Jersey City and St. Louis factories of the company, and is ready to go on any circuit to which it is adapted. In fact, Rossiter, MacGovern & Company are ready to equip complete plans for lighting or street railway work, and it would seem as though almost any want could be met from this complete and exhaustive catalogue covering every branch of the light and power industry.

NEW LEFFEL CATALOGUE.—The new catalogue of engines and boilers made by James Leffel & Company, of Springfield, Ohio, is a book that will interest many of our readers. It should interest any one who has to do with steam power. This book goes into the matter of the making of Leffel engines and boilers and shows on what their merit is based. It is well gotten up, printed on heavy enameled paper, has numerous full-page and many smaller illustrations, and is filled with just such detailed information about engines and boilers as to make it truly valuable to those using or contemplating using an engine or boiler. The book will be mailed free to prospective buyers of an engine or boiler, stating wants and addressing the company as above.

A FIREPROOF DREAMLAND.—The H. W. Johns-Manville Co., 100 William St., New York, is supplying the Dreamland Company, Coney Island, with several thousand squares of "Asbestoside" to be used for siding the buildings in "Dreamland," which will be the largest pleasure resort on Coney Island, and the summer attraction of several million people. "Asbestoside" was specified by the architects, Messrs. Kirby, Pettit & Green, of New York, and formally approved by the Building Department, which classified it as a "high grade, slow burning or fire retardent material." The distinctive features of "Asbestoside" are, that it is cut into sheets of 7 feet and crated; is easily applied being finished with large head galvanized nails which are covered with a half round wooden beading or moulding, and does not require painting of any description with the exception that the wooden strips may be tinted any desired color in contrast to the siding which is white. "Asbestoside" is superior to metal siding, along the sea coast, as it will not rust or decay and the first cost is cheaper, besides doing away with the annual coating.

THE STANDARD UNDERGROUND CABLE COMPANY, in conjunction with the McRoy Clay Works, has a joint exhibit in Section 3 immediately adjoining the northwest entrance of the Electricity Building, St. Louis. The exhibit shows a cross-section of an actual conduit consisting of 72 ducts, with a manhole at either end, one manhole being complete with a cover, the other being open. A trench 7 feet deep and 5 feet wide extends the entire length of this conduit, enabling close inspection of the method of laying conduits, including the wrapping, concrete base and top, and the general construction of the manholes, showing hangers, pipes to poles, etc. At one end in the manhole is shown a capstan rigged up for drawing in cables and connected to a cable which is mounted on a reel at the other manhole; the cable being drawn through the ducts and part of the ducts being split so as to show the method of fastening cables to rope, etc. From the manholes, cables go to distributing poles, showing the method of distribution to aerial cables for telephone, electric light and street railway work with various terminals used to protect the ends of the cable in such work. The McRoy Clay Works show piles of clay as it is dug from the ground and the various processes through which the material goes to produce the finished duct. The Standard Underground Cable Company shows samples in handsome cases of all the various cables and appliances made by it. An examination of this system will show, in very complete detail, the method of installing conduits and drawing cables into completed conduits.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MAY 3, 1904.

[Conducted by Rosenbaum & Stockbridge, Patent Att'ys, 140 Nassau St., N. Y.]

758,610. CONTROLLER FOR ELECTRIC MOTORS; Thomas E. Barnum, Milwaukee, Wis. App. filed Feb. 7, 1902. A number of switches connected in series and situated at a distance from the rheostat, for stopping and starting the motor independent of the rheostat.

758,621. HIGH TENSION CIRCUIT BREAKER; Harry P. Davis, Pittsburg, Pa. App. filed Sept. 13, 1902. A construction to prevent danger to neighboring objects from the arc and a means for indicating when the circuit breaker is automatically opened and another means for positively indicating at all times whether the breaker is open or closed.

758,623. TELEPHONE SYSTEM; William W. Dean, Chicago, Ill. App. filed May 11, 1904. (See page 913.)

758,631. COLLECTOR RINGS AND BRUSH HOLDERS; Karl F. Ehlers, Pittsburg, Pa. App. filed Sept. 26, 1903. The object is to provide brush-holder collecting rings for machines having a relatively large number of brushes which shall occupy the smallest amount of space.

758,635. DIRECT CURRENT GENERATOR; William H. Foot, Wilkinsburg, Pa. App. filed Sept. 16, 1903. Relates to the mounting of cross-connecting rings and their connections to the bars of the commutator.

758,638. LIGHTNING ARRESTER; Louis R. Gaw, Asbury Park, N. J. App. filed June 3, 1903. Details.

758,644. ELECTRIC ARC LAMP; Thomas Hamilton-Adams, London, England. App. filed Aug. 29, 1903. Two coils with tubular iron linings and connected in series are substituted for the usual solenoid, the said coils being wound in the same direction and placed one above the other some distance apart and mounted on a tube of non-magnetic material through which the upper electrode passes.

758,646. FUSE BLOCK; John A. Heany, York, Pa. App. filed Oct. 12, 1903. Details.

758,647. ELECTRIC SAFETY FUSE OR CUT-OUT; John A. Heany, York, Pa. App. filed Oct. 12, 1903. A non-conducting plug having an eccentric passage for the fuse with metal end caps having perforations corresponding in position to the bore of the tube, so that by twisting the caps, the fuse can be cut off at a definite length and then held in position by the cap.

758,648. ELECTRIC SAFETY FUSE OR CUT OUT; John A. Heany, York, Pa. App. filed Oct. 13, 1903. Special clamps adapted to engage the caps referred to in the preceding patent, to place them in circuit.

758,649. ELECTRIC SAFETY FUSE OR CUT OUT; John A. Heany, York, Pa. App. filed Oct. 14, 1903. A tube lined with a protective layer and having two metallic plugs arranged therein in which the fuse is centered.

758,650. ELECTRODE FOR VAPOR ELECTRIC APPARATUS; Peter Cooper Hewitt, New York, N. Y. App. filed Jan. 13, 1904. To prevent the spark where the current enters the negative electrode from wandering over its surface, a platinum point is projected from the surface of the mercury electrode, upon which the current enters.

758,655. MAGNETIC ORE SEPARATOR; William L. Imlay, Philadelphia, Pa. App. filed Oct. 2, 1899. Details.

758,669. BRUSH HOLDER FOR ELECTRICAL MACHINES; Benjamin G. Lamme, Pittsburg, Pa. App. filed Sept. 16, 1903. Details.

758,683. SYSTEM OF ELECTRICAL DISTRIBUTION; John S. Peck, Pittsburg, Pa. App. filed Aug. 8, 1903. A system for so distributing the self induction included in the alternating current side of systems of distribution employing rotary converters, that equal differences of potential may be obtained between slip rings belonging to the different phases.

758,684. MOISTURE PROOF CASE OR RECEPTACLE; John S. Peck, Pittsburg, and Albin L. Zwarnik, Braddock, Pa. App. filed Sept. 16, 1903. A corrugated metal casing with specially constructed joints for transformers.

758,692. STORAGE BATTERY; William J. Redmond, Cleveland, Ohio. App. filed Sept. 29, 1902. (See page 913.)

758,701. ELECTRIC BURGLAR AND FIRE ALARM; Solomon Schwarzschild, Rochester, N. Y. App. filed Feb. 24, 1902. A local circuit including an induction coil and vibrator is placed at the premises to be protected and is adapted to send a characteristic signal over a telephone circuit running to the premises.

758,703. APPARATUS FOR TELEPHONE LINES; Charles E. Scribner and James L. McQuarrie, Chicago, Ill. App. filed April 2, 1900. (See page 913.)

758,710. TITANOUS COMPOUND AND PROCESS OF MAKING SAME; Howard Spence, Manchester, Eng. App. filed Sept. 11, 1902. (See page 913.)

758,713. LEACHING APPARATUS; Geo. W. Stead, Philadelphia, Pa. App. filed July 26, 1902. The scrapers projecting into the pan have hinged lips that yield in one direction, but are stiff in the other, so that as the pan is reciprocated, the solid material is moved along the bottom of the pan step by step.

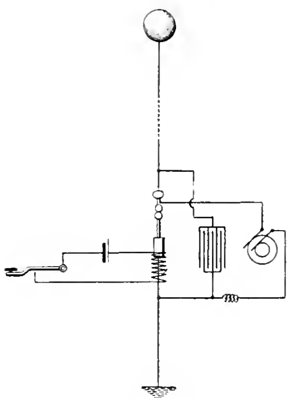
758,722. CONTROLLER REGULATOR; Vandiver J. Von Horn, Keokuk, Ia. App. filed Sept. 10, 1900. Details of a governing device which will enforce a gradual operation of the controller.

758,724. SIGNALING SYSTEM; Joseph Weatherby, Jr., New Cumberland, Pa. App. filed June 1, 1903. Details.

758,730. ELECTRIC LAMP; Alexander J. Wurts and Edward Bennett, Pittsburg, Pa. App. filed Jan. 10, 1901. The insulating frame upon which the parts of a glow lamp are mounted, is covered with a readily removable coat which receives the particles given off when the lamp is burning and by a timely removal of which short circuits may be prevented.

758,732. PRINTING TELEGRAPH; John C. Barclay, New York, N. Y. App. filed July 24, 1903. An arrangement of selecting relays and associated devices whereby the operation of a single relay in a single main line circuit controlling the selective action of the selecting relays, any one of a plurality of type-bars may be actuated at will.

758,650.—Electrode for Vapor Electric Apparatus.



758,842.—Wireless Telegraphy.

758,736. AUTOMATIC FIRE AND BURGLAR ALARM TELEGRAPH; Robert G. Callum, Washington, D. C. App. filed March 1, 1902. Details of construction of a transmitter.

758,775. APPARATUS FOR THE TREATMENT OF GASES; Harry Pauling, Gelsenkirchen, Germany. App. filed Nov. 20, 1903. Apparatus for the continuous treatment of gases by means of spark discharges in such a manner that every particle of the gas is brought into contact with the spark.

758,795. TELEPHONE RECEIVER; Ernest Hugo Strauss, Chicago, Ill. App. filed July 25, 1902. (See page 913.)

758,842. WIRELESS TELEGRAPHY; James F. King, Washington, D. C. App. filed Dec. 17, 1902. The improvement consists in creating a flaming arc in a normally closed generator circuit and simultaneously connecting around the arc a capacity in a vibratory circuit.

758,855. RAILWAY SIGNAL; Edward F. Ryman and Edward W. Stevenson, Wilkesbarre, Pa. App. filed Oct. 19, 1903. Details.

758,860. SELF PLAYING MUSICAL INSTRUMENT AND NOTE SHEET THEREFOR; Chas. A. Shaffer, Philadelphia, Pa. App. filed July 21, 1903. The several movements of the note sheet and the actuation of the notes are obtained by means of a metallic sheet having both surfaces covered with insulating material which is removed in spots where contact fingers are to close the circuit.

758,883. METHOD OF GENERATING GASEOUS MEDIUMS FROM AIR; James N. Alsop, Owensboro, Ky. App. filed May 29, 1903. (See page 913.)

758,884. APPARATUS FOR GENERATING GASEOUS MEDIUMS FROM AIR; James N. Alsop, Owensboro, Ky. App. filed May 29, 1903. (See page 913.)

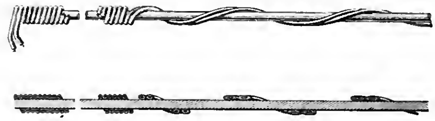
758,922. SIGNALING ON ELECTRIC TRACTION SYSTEMS; T. H. Jones, Portsmouth, England. App. filed July 7, 1902. Details.

758,938. AUTOMATIC MAGNETO CIRCUIT BREAKER; William M. Scott, Philadelphia, Pa. App. filed July 31, 1903. Improvements in the tripping mechanism.

758,946. ELECTROHEATER; Edwin R. Waterman, San Francisco, Cal. App. filed July 13, 1903. A liquid heater consisting of a number of concentric interspaced cylinders each containing electric heating devices.

758,954. AUTOMATIC CUT OFF IN TIME OF STORM; Frank P. Bell, Fairfield, Washington. App. filed April 24, 1903. Details.

758,977. GUARD COVERING FOR THIRD RAILS OF ELECTRIC RAILWAYS; John Kress, New Rochelle, N. Y. App. filed Dec. 30, 1903. A housing for the third rail in which the roof is divided into two laterally sliding parts, which are moved aside by the plow as it progresses and afterwards automatically closed.



759,120.—Electric Inductive Conductor.

758,986. TUBULAR INSULATOR; Fred M. Locke, Victor, N. Y. App. filed Nov. 11, 1901. A plurality of shelves one arranged within the other and having a double conical shape around the center of which the line wire is secured.

759,004. ALTERNATING CURRENT MOTOR; Burton McCollum, Lawrence, Kan. App. filed April 4, 1903. Means for producing in the field of the motor, a special component of magnetism in phase with the main component in space, but differing therefrom in time, preferably by 90°.

759,007. STORAGE BATTERY; Job Thomas Niblett, Greenwich, Eng. App. filed Feb. 5, 1903. (See page 913.)

759,026. ELECTRIC CLOCK; Herbert Scott, Bradford, and Alfred Loebl, London, England. App. filed June 10, 1903. A ratchet wheel and the oscillating means are obliquely arranged to each other, the driving pawl for the ratchet wheel being carried by the oscillating means with the parts so arranged that the power applied by the pawl to the wheel is in a substantially direct line with the movement of the actuated tooth.

759,047. ELECTRIC SIGNAL SYSTEM; George L. Vannais, Hartford, Conn. App. filed June 20, 1903. Details.

759,058. STORAGE BATTERY; Vincent G. Apple, Dayton, Ohio. App. filed June 5, 1901. (See page 913.)

759,060. ELECTRIC RAILWAY SWITCH-POINT AND OPERATING MEANS THEREFOR; Arthur J. Backer, Spracuse, N. Y. App. filed July 8, 1903. The magnet which throws the switch tongue is located in a chamber inside of the tongue itself.

759,062. DEVICE FOR DISTRIBUTING NOXIOUS FUMES; Lyman M. Beckes, Vincennes, Ind. App. filed June 26, 1903. The closure of an electric circuit by a burglar will release noxious fumes intended to overcome him.

759,065. METHOD OF ACCUMULATING AND USING ELECTRICAL ENERGY; Anson Gardner Betts, Troy, N. Y. App. filed Aug. 17, 1903. (See page 913.)

759,066. ELECTRIC STORAGE BATTERY; Anson Gardner Betts, Troy, N. Y. App. filed Aug. 17, 1903. (See page 913.)

759,094. TELEPHONE TRANSMITTER; James I. Gemmill, Cleveland, Ohio. App. filed Aug. 28, 1901. (See page 913.)

759,095. TELEPHONE RECEIVER; James I. Gemmill, Cleveland, Ohio. App. filed Dec. 22, 1902. (See page 913.)

759,096. FRICTIONAL ELECTRIC GENERATOR; Garabet Germakian, Paterson, N. J. App. filed Aug. 22, 1903. The generation of static electricity is aided by providing a heating device other than that due to friction, the heat of which is applied to the plate.

759,098. SAFETY DEVICE FOR ELECTRIC RAILWAYS; George Gibbs, New York, N. Y. App. filed Dec. 24, 1903. The invention is concerned with providing means for cutting off the current in classes of accidents where the working conductor is not interfered with, or in an emergency at the will of an authorized person.

759,119. ELECTRICAL CONDUCTOR; Percy A. McGeorge, West Hoboken, N. J. App. filed Sept. 10, 1902. Two conductors are placed in parallelism with a magnetic strip arranged between them, but electrically insulated, the object being to provide a magnetic as well as an electric conductor.

759,120. ELECTRIC INDUCTIVE CONDUCTOR; Percy A. McGeorge, West Hoboken, N. J. App. filed March 17, 1904. A modification of the preceding invention in which the magnetic conductor is spirally wound by the two electric conductors.

759,121. POLE CHANGER; Roger M. Newbold, Birmingham, Ala. App. filed Aug. 19, 1903. Details.

759,122. ELECTRIC DYNAMO; Roger M. Newbold, Birmingham, Ala. App. filed Nov. 3, 1903. A casing especially adapted to axle-driven railway car dynamos, permitting ready access to the parts.

759,148. ELECTRIC ATTACHMENT FOR ROCKING CHAIRS; Gaines M. Allen and Samuel M. Cawker, Denver, Colo. App. filed Nov. 3, 1903. The movements of the chair are utilized to generate a small current to electrify metal plates placed at various points on the chair, so that a person occupying the chair will receive the current.

759,150. MOTOR STARTER; William Baxter, Jr., Jersey City, N. J. App. filed Feb. 9, 1904. A motor starter provided with a main switch and a rheostat switch, both of which are controlled independently by a magnet that is energized by two coils, one being connected in series with the armature, and the other in shunt relation thereto.

759,166. POWER TRANSMITTER; George M. Eames, Bridgeport, Conn. App. filed Sept. 25, 1903. A device for driving sewing machines comprising a power transmitter which can be operated independently of the motor to stop and start the machine while the motor is continuously in operation.

759,210. SUPPORT FOR FIELD WINDINGS; Bernard A. Behrend, Norwood, Ohio. App. filed Dec. 7, 1903. The winding is supported upon the core by a supporting frame that sustains it interiorly and exteriorly.

759,216. WIRELESS SIGNALING APPARATUS; Lee De Forest, New York, N. Y. App. filed March 14, 1903. The receiving apparatus comprises a syntonic and non-syntonic receiving system, each containing a wave-responsive device; also an indicating device connected with both wave-responsive devices and oppositely effected thereby.

Electrical World and Engineer

CONTENTS.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

All the signs indicate that the convention of the National Electric Light Association in Boston next week will be one of the largest and most important ever held by that body. The engagement of rooms in advance—far exceeding any precedent—shows that the attendance will be very good, while the programme, which we present on another page, is evidence that there will be an abundance of live material for discussion. We give also a little sketch, which, we believe, will be of interest in a retrospective way, of the last convention held by the Association in Boston seventeen years ago. The programme then was indeed meagre as compared with the imposing list of papers, subjects and authors submitted by President Edgar for the coming week. But the same continuing spirit and policy have run through the history of the Association, and its evolution has been marked by steady good work. A few years ago it looked as though the Association had outlived its earlier usefulness, or at least had fallen upon days of restricted opportunity; but it is now easily to be seen by everybody that the responsibilities and duties of the Association to the electric light and power industry are larger than they ever were, and are being met in a manner to command respect and to ensure its growth.

MEETING OF THE INSTITUTE.

During the current week the American Institute of Electrical Engineers has held its annual meeting in New York City. The statement of the directors as to the affairs of the Institute is a highly creditable one, and to all who take interest in the Institute and in the advance of the profession, it must be encouraging to note that with the present month the membership has reached the remarkable figure of 3,000 with an immediately prospective total of 3,300. This rate of growth, of 800 or 900 new members a year, speaks volumes for the expansion of the profession and its allied arts, and shows that the Institute, on thoroughly equal terms, can hold its own with the other great national engineering societies, among which it is the latest comer. The financial affairs of the Institute are also in excellent condition in spite of heavy expenses assumed during the past year or two, while it is also a splendid proof of public spirit to find that the building fund for the Institute's share in the Union Engineering Building project has already been lifted over $60,000 by the contribution of members. The officers who have been elected to the Council are in themselves a pledge that the good work will go on. The new President, Mr. John W. Lieb, is representative of the highest type of electrical engineer and of all the noblest aims and aspirations of the Institute. He is a hard worker and a man of affairs and of culture, and one whose occupancy of the chair coincides happily with the year of the Congress and the visit of so many electrical friends from abroad.

NEW RESOURCES OF ILLUMINATION.

Whatever may be their final outcome, it is interesting to note that in our present issue, three of the newer electrical illuminants are treated under aspects which warrant a very hopeful feeling in regard to them as permanent and valuable additions to the resources of the electric lighting art. In fact, the details given with regard to the adoption of the Nernst lamp for the art galleries at the St. Louis Exposition; and concerning the successful employment of mercury vapor lamps in the largest automobile garage in the country, indicate that both of these forms of lamp are finding quickly spheres of utility and fitting into them. We must all welcome heartily such additions to the means belonging to the art, especially as the whole work and utility of illumination is thereby enlarged. As a general thing we have of late been slower or more timid than European engineers in taking up and fostering these new developments, so that even to-day some varieties of illuminants are in use across the Atlantic which have virtually never been seen here. Even if they are no good, our famous American curiosity and inquisitiveness ought at least to have brought them forward, so that judgment could be formed in regard to them from actual observation.

The third novelty, if we may so describe it, though it has less present actuality than the other two lamps to which our pages draw special attention, is the magnetite lamp. Mr. Charles P. Steinmetz describes this in a characteristic article, which we know will be read with great eagerness. Rumors and reports in regard to this new illuminant have been in circulation for some time past, and Mr. Steinmetz now to some extent gratifies the general desire for information of the subject, supplementing his text with some illustrations of the lamp and its arc. It is to be hoped that the new lamp will be on view in Boston next week, and if so, it will certainly constitute one of the leading novelties of the convention.

The Electrical Hub.

From the standpoint of the central station man the electrical situation in Boston is a most instructive one in many respects. If one were to pick out the features which seem most important to the engineer, the two most conspicuous would be the respective policies of the Boston Edison Company and the Boston Elevated Railway Company in the building up of their distribution systems. The former is an admirable evidence of the progressive instincts of the talented engineer who is the head of the system. The problem which he had to solve was the welding into a coherent whole not only of two diverse urban systems of distribution, but of a group of suburban stations of most heterogeneous character. The task with all its inherent difficulties has been accomplished in a most workmanlike fashion. From the great alternating central station energy is being transmitted more than thirty miles to suburban customers, while the direct-current urban service has been preserved in its integrity, and the improvement in service all over the territory served has been very marked. It is a remarkable example of deft adaptation in a rather trying combination of conditions. The other is the very striking and successful policy of segregated stations of the Elevated Company. The feeding of so great a network from a skillfully planned group of allied stations stands alone in American central station working. In almost every instance this condition has been met elsewhere by generation of power at a single central station and distribution at high tension to sub-stations. We should much like to see a disclosure on the matter of cost of power as between the Boston system and those operated with converter substations. From what data is available on the subject, we are inclined to the opinion that the Boston stations would not come out second best. The sub-stations certainly produce power within a very small percentage of the figure reached by the large new station, and the latter will compare favorably with the best figures reached elsewhere.

Measurement of the Insulation Resistance of an Electric Wiring System.

There is very little trouble in measuring the insulation of an electric plant or wiring system when the plant has been shut down. The system is then an inert network of conductors. But when the plant is at work, or in popular language "alive," the measurement is neither so easy nor so convenient. The difference brings to mind the relative degrees of convenience in measuring the span of an eagle's wings dead and alive. The article of Mr. E. F. Northrup on page 966 relates to the methods of insulation measurement in a working system. These methods are not entirely new, but they are well presented and are set in very practical form. Two methods are described. In the first the source of testing e.m.f. is the generator or set of generators working in the system. A reading of potential to ground from each side of the system through a voltmeter of known resistance, together with the magnitude of the working voltage, suffices to determine the apparent insulation of the system on each side. In the second method, which is better adapted to relatively high insulations, a separate testing e.m.f. is used independently of the working e.m.f. in the system, and the testing e.m.f. is applied to the system at a point such that no appreciable disturbance is effected. The latter method is capable of being employed with a three-wire system, or with a system of any number of wires; but the former method requires some modification to meet the requirements of a working three-wire system.

The Protection of Telephone or Telegraph Lines When in Hazardous Proximity to High Tension Lines.

The article on this subject, by Mr. R. E. Chetwood, Jr., appearing on page 968 of this issue, is of much interest as representing the most modern practice of the Bell Telephone system. The engineering department of that company has faced the problem under consideration for a number of years, and has had a very wide experience in the nature and conditions of the hazards to which overhead telephone wires are exposed by crossing the route of high-pressure wires. The importance of adequate protection from high-tension crosses is manifest after a moment's consideration. If a high-tension line carrying power electrically at a pressure of many kilovolts crosses the route of a telephone pole line, the high-pressure wires must cross either above or below. It is desirable that they should cross above the telephone lines, because the high-pressure wires, being usually much the stouter, are less likely to break accidentally. Nevertheless, there is always the remote possibility of an insulator breaking on one of the poles of the cross-over, thereby bringing much electric pressure on the cross arm, which might burn off and let the high-pressure wire fall upon the telephone wires below. If, on the other hand, the telephone wires cross above, their number may be considerable, say, 30 or 40, and at some time one of these wires may break in the cross-over span, thereby falling on the high-pressure wires below.

In either case the contact between high-pressure wire and telephone wire may be fraught with disastrous consequences. The best result that can be looked for is the rupture of the small telephone wire, at or near the point of contact, whereby the high-pressure connection immediately ceases. If the telephone wires does not break, the high pressure of the transmission wire is led into the telephone central station at one end, and into the telephone subscriber's premises at the other. In each of these places it is the unvarying custom to install protective devices, which are designed either to open or ground the circuit, and to remove the pressure from the terminal apparatus. There is, however, always the remote possibility of something going wrong at a protective device, whereby it may fail to operate. In such a case the high pressure on the telephone line might destroy apparatus at either end, and, under particular conditions, might initiate a fire. It is physically possible for a cross between a telegraph or telephone line and a high-tension line to initiate a fire in a building a hundred miles away from the cross, the high-pressure being capable of carrying a dangerously strong current to similar distances.

Moreover, every year sees more wires strung across the country, more telephone and telegraph wires, and more high-pressure transmission wires. This is only another way of saying that civilization and material wealth are advancing. Nevertheless, there is no cause for undue apprehension merely because the network of line crossings is increasing in complexity. We all know that the staunchest steamer ever built may founder if she collides in midocean with another vessel. The chance for collision undoubtedly increases with the number of ships along the course, and more ships are sent to sea from year to year. The greater the speed of a vessel, other things being equal, the greater the chance of a collision, yet although ocean speeds are increasing, we do not hesitate to embark on a voyage to Europe whenever opportunity smiles upon occasion. The correct course, therefore, is neither to ignore the dangers of high-tension crosses on the one hand, nor to take unreasonable alarm on the other; but to provide against accidents by engineering methods. Since engineering brings about the danger, engineering is able to minimize it. Every step taken from barbarism towards civilization entails some penalty of danger. Tall buildings may totter and fall in an earthquake. Railway trains may be wrecked. Illuminating gas supply may give rise to explosions in buildings. Yet none of these things cause us dismay. We face them confidently with engineering methods.

Mr. Chetwood's article sets forth methods of cross-over construction which are designed to reduce the possibility of accidental crosses to a minimum. The preferred construction is a short cross-over span, with the high-pressure wires above, on double insulators, but not dead-ended. The insulators have steel pins which are grounded. If this plan is impracticable, the telephone wires go over on a short span. Where short spans cannot be used, guard wire spans are introduced. The interesting feature of the high-tension guard wires is that when grounded they must be capable of carrying three times the normal high-tension line current. The real difficulty in many cases is to make an effective ground. The method described is probably the most satisfactory known under the conditions of practical line construction. It consists in employing a galvanized-iron rope and burying a coil of half a dozen turns, not less than eighteen inches in diameter, at the depth of permanently moist earth, in three bushels of fine coke. The general features of the cross-over construction described seem to be well worthy of imitation, which in such cases is known to be the sincerest form of flattery.

Electric Fire Risks.

The last quarterly report from the electrical bureau of the National Board of Fire Underwriters is just at hand, and like its predecessors it contains much that is instructive. The good old times when every fire of unknown origin was charged up to electric circuits have gone by, but the habit of years is hard to break, and we are not surprised to see the report of 181 fires "supposed to be due to electricity." To do the board credit, these fires are not included in its report as electrical, but the average fire chief or inspector greatly dislikes having to report a fire as of unknown origin and evidently soothes his soul by accusing the almost omnipresent electric wire. Fifty other fires charged to electricity proved to be due to quite prosaic causes like overheated stoves, matches and cigar stubs. However, the accredited list shows 135 fires definitely traced to electrical causes; and while this is not a large number considering the almost universal presence of electrical circuits in American cities, it is great enough to bear considerable reduction. From the standpoint of the electrician it is gratifying to note the comparatively small proportion of the total fires due to actual bad construction on the part of the electric light circuits. By far the largest proportion of the fires were caused by the hopeless and irremediable foolishness on the part of the users of electric current. A smaller but still conspicuous proportion was caused by crossing of telegraph or telephone wires with electric light wires. We would much like to know what number of these, if any, came from the fault of the latter. It almost seems as if bad construction were at a premium on these slightly constructed circuits, for their wires seem to break and fall upon the heavier wires beneath on the smallest provocation.

But the plain everyday fool seems to have been the active agency in most of the cases adduced. We should have supposed, for instance, that at this date people of the most ordinary intelligence would have awakened to the fact that incandescent lamps if placed in a confined space in contact with inflamable material are unsafe. But each report brings the same old tale of woe. Even the incandescent lamp as a foot warmer on cold nights comes to the front with each succeeding winter, and each holiday season brings back the fine old sure-fire combination of lamp-bulb and cotton waste. One would suppose, too, that people would have learned to be careful about driving nails through electrical conduits, mixing up electric wires and gas pipes, replacing fuses by copper wire, and all that sort of thing, but they seem to go on in the same old way. Misused flexible cords seem to be responsible for frequent difficulties. But there are still left, after eliminating the fool, a moderate proportion of fires due to bad or stupid house wiring. The old open link cut-out scores quite too frequently. In these days it surely should be replaced by something better, or at least placed where it can do no harm. Even relatively poor material can do good service if it is used discreetly, while the very best can be made dangerous by misuse. When one couples poor material and bad judgment, the combination is invincible. We often wish that the Board of Fire Underwriters would use its power less in general recommendations than in seeing that specific ones are honestly carried out. The modern American frame house is more or less of a fire trap at best, and when built on speculation by an avaricious and unscrupulous contractor, it becomes a menace to public safety.

Every insurance inspector can enumerate a long list of atrocious violations of all rules of decent construction by thievish wiring contractors, and denounces them with hearty indignation in which we earnestly join. There is in these days absolutely no excuse for dangerously bad interior wiring such as is continually being discovered, often, alas, too late. The Board of Fire Underwriters can do more to prevent this than any other power, and in a campaign for good work it will have the cordial support of the electrical public at large, and the support, too, of every honest electrical contractor. For the honest man who insists on doing only good and thorough work is continually robbed of business by the chap who scamps his materials and leaves his work half done. We have personally seen scores of houses being wired in a way that simply courts danger from fire, both as regards material and method of installation. Some of the jobs met the letter of the law; none of them would have passed an honest inspector with any discretionary powers. The bad work of last year and the year before insures fire risks this year and next, and we would like to see opened a campaign of education and rigid inspection for the enforcement of safe installation. The stake is a large one; even though electrical fires have been greatly reduced in number of late years the aggregate annual loss to the insurance companies from this cause would pay for the services of a tremendous force of competent inspectors. Each contractor rigorously brought to book is less dangerous for the future, and by the same token the public is safer. We think the board has erred in the past in trying to do too much in general and too little in detail; in making sometimes hypercritical distinctions in its approved materials of construction, and paying too little attention to the manner of their use in concrete cases. It is quite possible to do a "cheap and nasty" job of wiring with approved material and still follow the letter of the code, and the fellow who does this generally is able to work off poor material to boot.

Programme of the National Electric Light Convention.

The following is the detailed programme of the proceedings of the National Electric Light Association meeting to be held at the Hotel Vendome, Boston, next week. It will be the twenty-seventh convention:

Tuesday, May 24, First Session, 10 o'clock A.M., Convention Hall, Hotel Vendome.—President's address, Mr. Charles L. Edgar, Boston; report of Committee on Progress, Editor Mr. T. Commerford Martin, New York; "A Three-Wire, 500-Volt Lighting System," Walter I. Barnes, Providence; "Luminous or Flaming Arc," Mr. Welles E. Holmes, Newton; Committee on Standard Candle-Power Incandescent Lamps, Dr. Louis Bell, Boston, chairman; Committee on Legislative Policy, Mr. Samuel Insull, Chicago, chairman; Committee on Photometric Values of Arc Lamps, Mr. Henry L. Doherty, Denver, chairman; Committee on Uniform Accounting, Mr. Guy L. Tripp, Boston, chairman.

Tuesday, Second Session, 2 o'clock P.M.—"A One-Hundred-Mile Transmission Line," Mr. Robert Howes, Spokane, Wash.; "Grounding the Neutral of High-Voltage Generators," Mr. George H. Eastman, Chicago; "Remote Control of Electrical Apparatus," Mr. William H. Cole, Newton; "The Organization and Equipment of an Arc Lamp Department," Samuel G. Rhodes, New York; "Electric Heating," Mr. James I. Ayer, Cambridge; report: Lost and Unaccounted-for Current, Mr. C. W. Humphrey, Denver.

Wednesday, May 25, Third Session, 10 o'clock A.M.—"Economy in Minor Station Supplies," Mr. Edgar B. Greene, Altoona, Pa.; "Notes on the Internal Combustion Engine as Applied to Central Station Service," Mr. E. E. Arnold, Pittsburg, Pa.; "Economy Test of a 5,500-hp Three-Cylinder, Compound Engine and Generator.," Messrs. J. D. Andrew and W. F. Wells, New York; "The Mechanical Stoker and Human Operator," Mr. Edwin Yawger, Pittsburg; Committee on Award of Doherty Gold Medal, Dr. Schuyler S. Wheeler, Ampere, N. J., chairman; report: Investigation of Steam Turbines, Mr. W. C. L. Eglin, Philadelphia, chairman; "Practical Notes on Steam Turbine," Mr. Francis Hodgkinson, Pittsburg, Pa.

Thursday, May 26, Fourth Session, 10 o'clock A.M.—"Electric Light and Power Plants in Connection with Ice Plants," C. L. Wakefield, Dallas, Tex.; report on Sign and Decorative Lighting, Arthur Williams, New York; report on Advertising, La Rue Vredenburgh, Boston; report on Purchased Electric Power in Factories, W. H. Atkins, Boston, chairman; report of Committee on District Heating, E. F. McCabe, Lewistown, Pa., chairman; report on Office Methods and Accounting, Frank W. Frueauff, Denver.

Thursday, Fifth Session, 2 o'clock P.M.—"A Proposed System of Standard Instruments for Operating Companies," H. P. Davis, Pittsburg, Pa.; "Single-Phase Power Motors for Electric Lighting Stations," W. A. Layman; report on Analysis of Flue Gases, Henry L. Doherty, Denver, chairman; "Wrinkles," Editor Charles H. Williams, Madison, Wis.; "Question Box," Editor H. T. Hartman, Philadelphia, Pa.

Thursday, Sixth Session, 8 o'clock P.M.—"Types of Large Water Power Installations," with stereopticon, Dr. F. A. C. Perrine, Pittsfield. Executive Session.

An excellent programme of trips and entertainments has been provided, note of which has already been made and which will be carefully arranged in detail. The chairman of this committee is Mr. J. I. Ayer, and the members are: Prof. C. A. Adams, Albert Anderson, William H. Atkins, F. E. Barker, F. P. Barnes, R. N. C. Barnes, George H. Berg, H. Bottomley, Capt. William Brophy, F. E. Cabot, C. W. Cartwright, A. E. Childs, A. T. Clark, Prof. H. E. Clifford, S. B. Condit, Jr., Charles B. Davis, R. B. Edes, George C. Ewing, H. H. Fairbanks, H. C. Farnsworth, George H. Finn, Almon Foster, W. C. Fish, H. A. Hale, Charles J. Hatch, Percy Hodges, W. E. Holmes, C. W. Holtzer, Sydney Hosmer, P. J. Kennedy, A. H. Kimball, George B. Lauder, F. W. Lord, Emil O. Lundin, Norman Marshall, E. H. Mather, Everett Morss, H. W. Moses, W. L. Mulligan, J. H. Parker, H. S. Potter, C. B. Price, C. F. Prichard, Andrew Raeburn, F. H. Raymond, F. S. Richardson, Frank Ridlon, D. P. Robinson, F. P. Royce, G. L. Sadler, F. S. V. Sias, F. E. Smith, Prof. H. B. Smith, J. A. Smith, J. Brodie Smith, George B. Stetson, F. J. Stone, G. M. Stuart, La Rue Vredenburgh, Thomas C. Wales, R. L. Warner, N. T. Wilcox, S. B. Wetherbee, F. S. Wilson, Paul Winsor, W. C. Woodward.

The Executive Committee of the Association will hold a meeting on Monday evening. The members are: Louis A. Ferguson, Harry Bottomley, Alex. Dow, A. C. Dunham, J. H. Perkins, C. F. Hewitt, D. P. Robinson, P. G. Gossler, H. T. Hartman. The officers of the Association are: C. L. Edgar, president; S. B. Livermore, first vice-president; J. W. Lieb, Jr., second vice-president; E. H. Davis, secretary and treasurer; Harriet Billings, assistant secretary; George F. Porter, master of transportation. The usual fare and a third applies on all trips to the convention. The Southwestern Excursion Bureau has granted a rate of a fare and one-third on the certificate plan from all points in its territory to Boston and return to delegates and friends attending the twenty-seventh convention. This is the first time the concession has been made in this territory, and is additional evidence of the geographical as well as numerical growth in membershhip. The reduced rate has now been granted by all the passenger associations, and if the applications already received for rooms at the Boston hotels are any indication, the rate will be very generally taken advantage of.

Tesla on the Patent Office.

The New York *Sun* of Wednesday contained a letter from Mr. Nikola Tesla in which, referring apparently to recent publications concerning difficulties between Edison and the Patent Office, he takes up the cudgels for the office and is particularly complimentary in references to its technical staff. In a long personal experience he said he has found the examiners to be far more satisfactory than he had thought possible, and many times he has noted with astonishment the thorough grasp of ideas, the keenness of the criticisms and the exhaustiveness of the search for anticipations, while invariably he has obtained valuable information through the references cited and the suggestions made. He considers any criticism capable of creating a doubt in the minds of people as to the faithful performance of duties and competency of its staff must be deemed unfortunate, since such doubt may destroy confidence in the value of patent property. Mr. Tesla advocates more liberal appropriations and more suitable quarters for the Patent Office, and refers to the fact that owing to low salaries difficulty is found in retaining the services of competent men.

While examiners, he says, can never keep quite abreast with inventors, they are men well educated and trained, recruited from colleges, and to obtain appointment have to pass a severe examination covering the several branches of applied and cognate sciences. Serious dissatisfaction then is not likely to arise from the examiners' insufficient knowledge or lack of comprehension, nor is it apt to come from an inherent defect of adopted procedures, although some of these might be omitted to advantage. For example, the suggestion of claims by the examiner in a case of conflicting applications is, in my opinion, always in favor of the inventor possessed of better knowledge and stronger imagination. The introduction of greater rigidity in the withdrawal and amendment of specifications might also be helpful. But, after all, what difference does it make how the original documents are modified? The successive changes are all recorded and can be examined at any time. If new matter is injected in an amended application it will not be permitted to remain, and, ultimately, the testimony in the interference will bring out the exact facts which will settle the question of priority. The advantages which might be secured by such or similar changes would be slight. Of late years the demand on certain departments has been increasing so fast that more expeditious methods had to be adopted; and this has naturally detracted from the quality of the work. The remedy for this is a liberal appropriation.

Mr. Tesla considers that one of the greatest problems confronting the world is to devise methods and means for protecting intellectual property. "As we develop, this need asserts itself more and more. The ultimate aim should be to arrive at laws and regulations at least as precise as those which define the ownership of tangible things. A new principle is still to be discovered which will make this possible. Perhaps in the distant future photographic records of the retina of the eye may furnish a foundation for a new and more perfect system of protection and just valuation of the creations of the mind. As far as I am able to understand the working of the human mechanism, such records offer the only chance of doing away with the present imperfect ideas of possession and use of crude equivalents. But let us bear in mind that for the time being the United States Patent Office is the farthest advance toward that ultimate aim. Taking this broader view of the institution we shall better appreciate its immense influence on the welfare and morals of the country."

Fig. 1.—View of Boston Edison Station from the Harbor.

Expansion of the Boston Edison System.

SIXTY thousand kilowatts is to be the ultimate generator capacity of a steam turbine station that is being constructed by the Edison Electric Illuminating Company in Boston. The site of this new station is a plot of land 810 ft. by 1,300 ft., bounded on three of its sides by L Street and East First Street, South Boston, and by the Harbor Commissioners' line. A portion of this plot, perhaps one-third, is now under tide water, and is occupied in part by the coal wharf and the docks of the company. On the dry portion of this area, and not far from its center, is the old Fourth or L Street generating station of the Edison Company, which was built by the Boston Electric Light Company in 1898, and passed to the Edison Company with the purchase of the entire Boston electric system in 1901. An elaborate 26-page article on the then existing Boston system, by Mr. E. S. Mansfield appeared in Electrical World and Engineer in May of that year.

The new turbine station adjoins the generator room of the original plant, fronts Boston Harbor at a distance of about 128 ft. from the water line at the present bulkhead, and is designed to extend back, ultimately to the East First Street line of the property. In plan the new station is, with small exceptions, at its front end, a rectangle of about 252 ft. parallel with East First Street, and about 638 ft. parallel with L, and with the longer side of the old plant.

The ground area represented by these figures is that of the proposed station when fully completed, but at present only the front or harbor end of the station is being built. The length of this portion parallel with L Street is about 230 ft. in its largest part. On the ground where parts of the propsed station will set there are now located several old buildings that will in the future be removed. In general elevation the new station has one high story, but this is varied by a basement under the boiler room, and by dividing the switch house into three low stories with a basement underneath. In general structure the new station is built entirely of concrete, brick, stone, tile and steel from foundation to roof. The main walls of the station, both exterior and interior, are of brick, and the exterior walls, especially on the harbor front, have heavy stone trimmings that give a decidedly ornamental effect. At the harbor end of the turbine room, which juts out a little beyond the boiler room, there is a great arched window whose keystone bears a figure of Mercury, and just above this figure comes the word Edison beneath the letters MCMIII. At either side of this window is a great metal globe in which an arc lamp will be mounted.

As to its interior the new station is divided into the boiler house, the turbine house and the switch house by heavy brick walls that run parallel with the greater dimension of the building. The boiler house thus formed will have interior floor dimensions of about 146 by 630 ft. In the steam turbine house the width is about 65 ft. and the length 642 ft. The front or harbor end of the section of the station called the switch house is devoted to offices, and back of these offices the space on each floor available for switching purposes measures approximately 28 by 562 ft. This switch house adjoins the generator room of the original L Street station on one side and the new turbine room on the other, and communicates by doors with both.

In the design of the new station the controlling idea has been the division of all apparatus into isolated groups in order to reduce as much as possible the damage and delay that might result from any disaster. The unit of division selected for this grouping is the combined steam turbine and electric generator, and the apparatus connected to this unit is distinct, starting with its boilers and ending with its switches. More than this the elements of each group of switching apparatus are separated, the terminals of the generator cables being located in the basement of the switch house, the bus-bar compartments on the floor above, the high-voltage oil switches on the second floor and the controlling switches on the third floor.

The turbine house when completed is designed to contain twelve generating units each rated at 5,000 kw. These turbo-generators will be arranged in a single row from end to end of the turbine house, so that the center of each is about 11 ft. from the wall that separates the turbine house from the boiler house. In line with each turbine unit, but located on the other side of the wall just mentioned, is the row of eight boilers that supply it with steam, each of which has a nominal rating of 500 hp, or 4,000 hp for the group. Each row of eight boilers is set in four batteries and runs across the smaller floor dimension of the boiler house, so that when completely equipped this house will contain twelve parallel rows of boilers. Each group of eight boilers supplies steam to only a single turbine and its pumps. The rows of boilers are arranged in six pairs, the two rows of each pair being back to back with a chimney between them for their common use.

This chimney sets midway between the ends of the two rows of boilers, and has two flue openings in its opposite sides. The eight boilers forming the opposite halves of each pair of rows at one end connect with their chimney through a common flue, and the eight boilers that form the opposite halves at the other ends of the same rows connect with the other side of the chimney through another common flue. Tile arches between steel beams form the floor of the boiler room, and this floor is supported by the brick walls and by steel columns that rise from the basement foundations to the steel beams that carry the roof. These steel columns are so spaced that each boiler sets between and is supported by two of them at both its back and front ends. In this way six of the steel columns carry each battery of two boilers. Beneath the entire boiler room there is a basement whose concrete floor is just on a level with that of the turbine room, but is 18 ft. below the floor of the boiler room.

Down into this basement beneath each boiler projects a brick, concrete and steel ash chamber, which receives the ashes as they fall from the grate above. The bottom of each ash chamber, which is about 8½ ft. above the basement floor, opens by mechanical means so that the ashes may drop by their own weight into either a cart or conveyor underneath. In the basement beneath the rear part of each row of boilers there is a space where the steam and water mains for the boilers of that row are located. The steam pipe from each of the eight boilers in any one row drops at once to this steam main, and this main passes directly through the brick wall that separates the turbine and boiler houses, and to the particular turbine that is in line with this row of boilers.

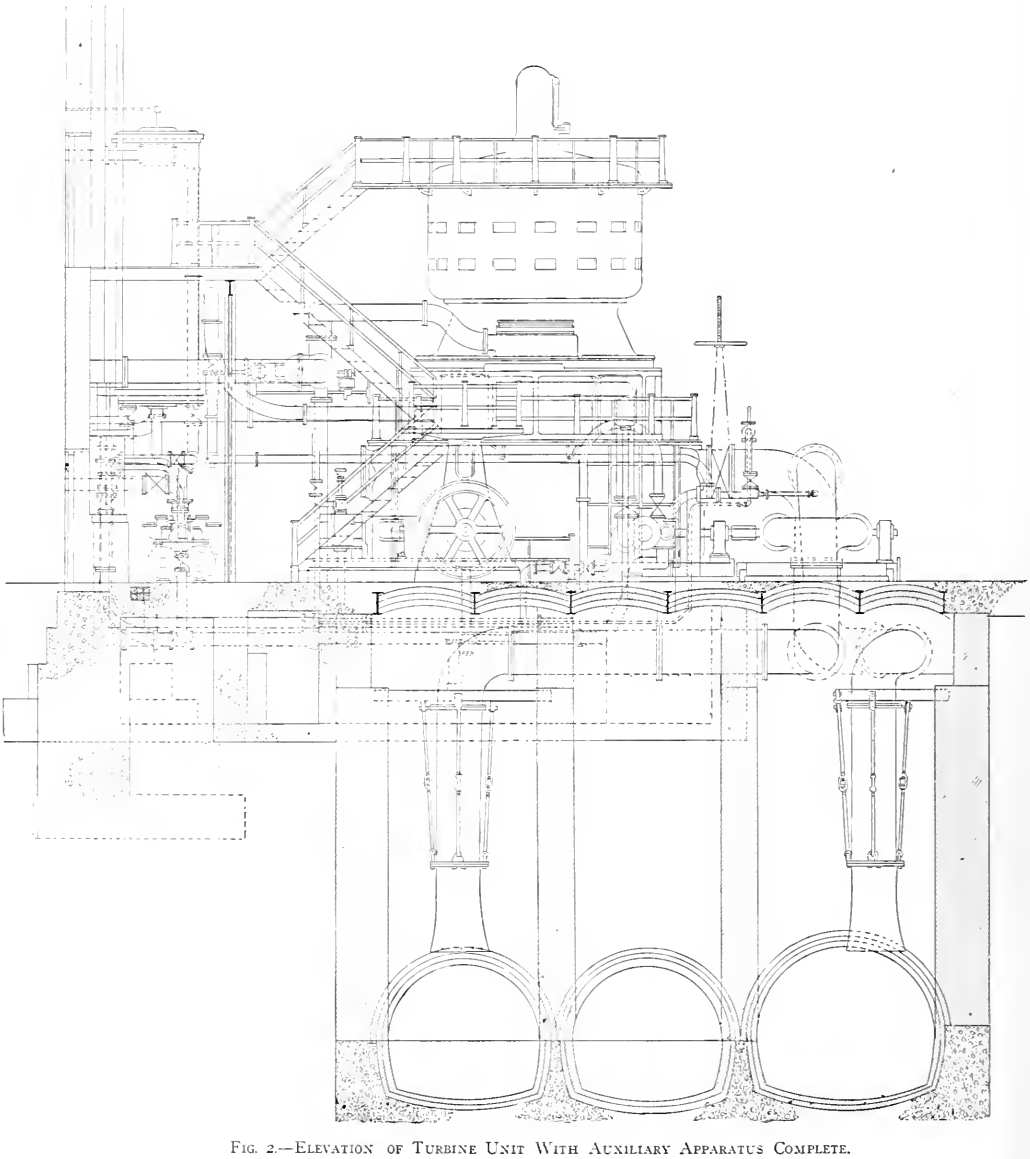

FIG. 2.—ELEVATION OF TURBINE UNIT WITH AUXILIARY APPARATUS COMPLETE.

Above the front side of each row of boilers and extending in part above the roof of the boiler house there is a coal conveyor and bunker of steel, tile and concrete construction, supported on the steel roof beams. The top of this coal bunker is 79 ft. 5 in. above mean low tide water. From this bunker the coal feeds by gravity down to the mechanical stokers in front of the boilers. At the harbor front of the boiler room light is supplied through a row of large windows in the wall, and beneath each large window there are two small windows and also a door leading onto an iron balcony to enable firemen to get readily to the outside air. Windows and large doors admit air to the basement, and all the air for the boiler furnaces enters in this way and passes up to the fires through openings in the sides of the ash pits. In the long outside wall of the boiler house parallel with L Street there is a large window and there are also two small windows and a door opening onto an iron balcony opposite each aisle between the fronts of rows of boilers. On the roof above each of these aisles there is a monitor skylight.

The concrete floor of the turbine house on a level with that of the boiler house basement, and 16 ft. above mean low tide water, rests on the concrete foundations of the station and has no basement under it. The entire turbine house when completed will be divided by cross brick walls into three rooms of nearly equal length, and each of these rooms will contain four of the turbine units. In each of the brick walls between turbine rooms there will be a great window like that at the outside end on the harbor front, and the end on East First Street will also contain a similar window. Besides these windows there will be a skylight along nearly the entire length of the roof. In the brick walls of the turbine room on its longer sides there are steel columns that run up from the basement foundations and support crane beams and also the steel roof trusses. The lower chords of these trusses are 56.5 ft. above the floor of the turbine room.

Beneath the floor of the turbine room are three sluiceways that carry sea water for condensing to and from the turbine units. Two of these sluice ways are equal in size and each of these carries the cold sea water to six turbines. The third sluiceway is larger and carries the heated water from the entire row of twelve turbines back to the harbor. Each of the sluiceways is of horseshoe shape, and the discharge sluice is 10 ft. wide and 9 ft. 3 in. high. In width each of the smaller sluices is 8 ft. 3 in., and in height 7 ft. 9 in. All three sluices have the same bottom level and the top level of each of the suction sluices is 21 ft. 9 in. below the floor of the turbine

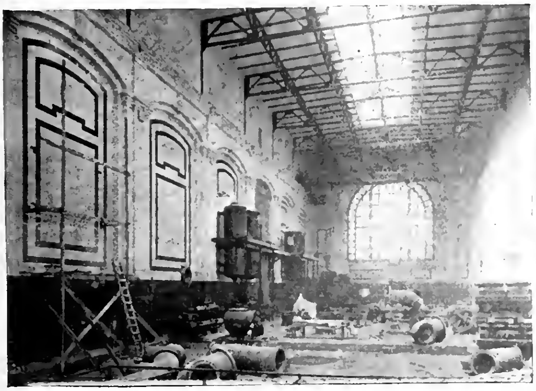

FIG. 3.—INTERIOR OF NEW PORTION, BOSTON EDISON PLANT.

room and 3 ft. 9 in. below the water level at mean low tide in the harbor. Directly in front of the turbine house and about 108 ft. therefrom are the gates for the suction sluices and beyond these but just inside of the face of the bulkhead is the large entrance chamber where the two suction sluices terminate. A channel has been dredged from the mouth of this chamber out into deep water, and over its mouth a screen is located to keep floating objects out of the suction sluices. The discharge sluice goes clear to the face of the bulkhead and a deflecting wall gives the hot discharged water a direction away from the entrance chamber.

Near each turbine unit there are grouped a centrifugal pump with direct-connected engine to handle the condensing water, a wet vacuum pump direct-connected to its driving engine, a steam-driven boiler feed pump, a steam-driven oil feed pump for the step bearing of the turbine, an accumulator to store oil under pressure for the turbine bearing, a separator between the condenser and the dry air pump to prevent the passage of water to the latter and a feed water heater and a hot well for the storage of water arranged side by side on the wall. Feed water for the boilers is drawn from the city mains and this water after condensation is used over and over, so that the loss is very small. Much of the piping between the various pieces of apparatus just named is carried in conduits beneath the concrete floor of the turbine room. Other conduits beneath this floor receive the electric cables from the turbines, and these cables then pass to the basement of the switch house where the floor is 2 ft. 3 in. below that of the turbine. After emerging from the cable terminals in this basement the high-voltage cables run to motor-operated oil switches on the second floor of the

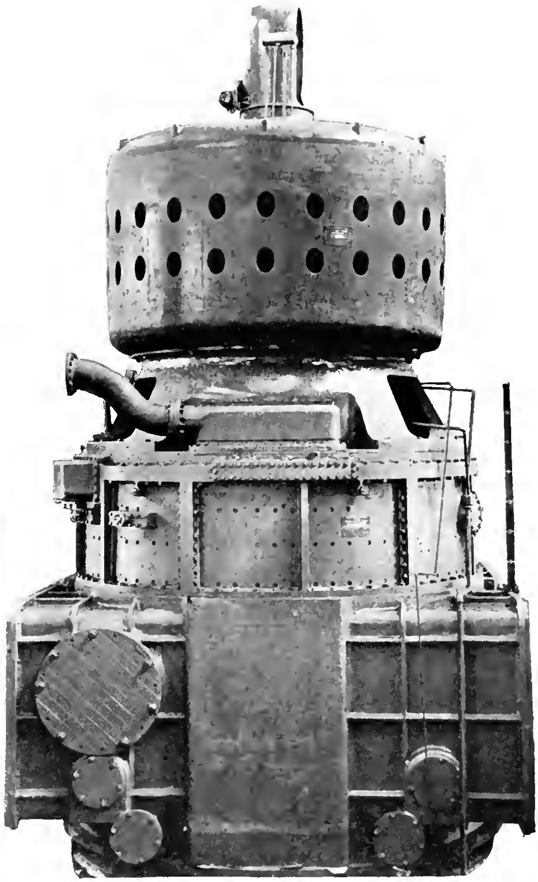

FIG. 4.—FOUR-STAGE CURTIS 5000 KW TURBINE FOR BOSTON PLANT.

switch house, and these switches complete the connections with the four sets of bus-bars on the first floor. On this first floor there are also located the knife switches for opening lines that are not in use, the lightning arresters and the instrument transformers.

The operating room of the switch house is on the third floor and here are located control switches for the oil switches below that make connections between the bus-bars and the generators and the outgoing cables. On this floor there are also control switches for the transformers that raise the voltage of the current from the generators in the old station, and also exciter panels for all of the generators in both the old station and the turbine station. The Corey signal system for both stations is also on this floor. As already pointed out, the switch house lies between the generator room of the old station and the turbine room of the new. From the operating room of the switch house one may pass through a door on one side to the switchboard gallery of the old station, or through a door on the opposite side to an observation gallery that projects out into the new turbine room.

In that part of the old station on the opposite side from the switch house is the coal pocket, and directly in line with this pocket is the coal wharf of the company which extends out into the dock a distance of about 368 ft. On this wharf there are now two coal derricks and a third is to be added. One of the present derricks has a one-ton bucket and works on only one side; the other derrick has a 1½-ton bucket and works on either side. The third derrick will have an equal capacity with the second. Running almost the entire length of the coal wharf and into the coal pocket there is a Robins 36-in. belt conveyor with a maximum capacity of 700 tons of coal per hour. A Hunt conveyor in the coal pocket distributes the coal. At the front end of this pocket there is a crusher that reduces the run-of-mine coal to 4-in. cubes.

Before entering the crusher the coal passes over a sort of screen or grating that allows the finer parts to fall through. Adjoining the coal pocket side of the old station and approximately 288 ft. by 516 ft. in area there is an open air yard for the storage of coal. The storage of coal on this large scale is thought to be desirable to avoid any possible shortage and because the cost per ton of the transportation of coal by water to Boston is the best part of a dollar higher in winter than in summer. In order to distribute coal over this large open storage area, belts numbered 2 and 4 are located across the end of No. 1 belt, that runs along the wharf as already mentioned, and No. 3 belt that is located in the open yard parallel with No. 1. The belts of conveyors Nos. 2, 3 and 4, like No. 1, are each 36 in. wide. After the coal has been dumped in a narrow pile extending the length of the yard under belt No. 3, it must be moved and piled in other parts of the yard, and for this purpose a Brown traveling bridge is employed.

This bridge is a steel truss 248 ft. long mounted on steel towers that move on tracks which extend the entire length of the yard. One of these tracks has a single and the other has two rails, and the distance of these tracks between centers is about 156 ft. One of its supporting towers is under that end of the bridge which is the more distant from the coal pocket in the old station, and the other end of the bridge overhangs the No. 3 belt conveyor that runs nearly the length of the yard. Beneath the bridge there is a motor-driven carriage that carries an attendant and also a 2-ton coal bucket. This carriage travels the entire length of the bridge, and this motion, together with that of the entire bridge up and down the yard, enables coal to be picked up at any point therein and dropped either on the belt conveyor or at any other point in the yard.

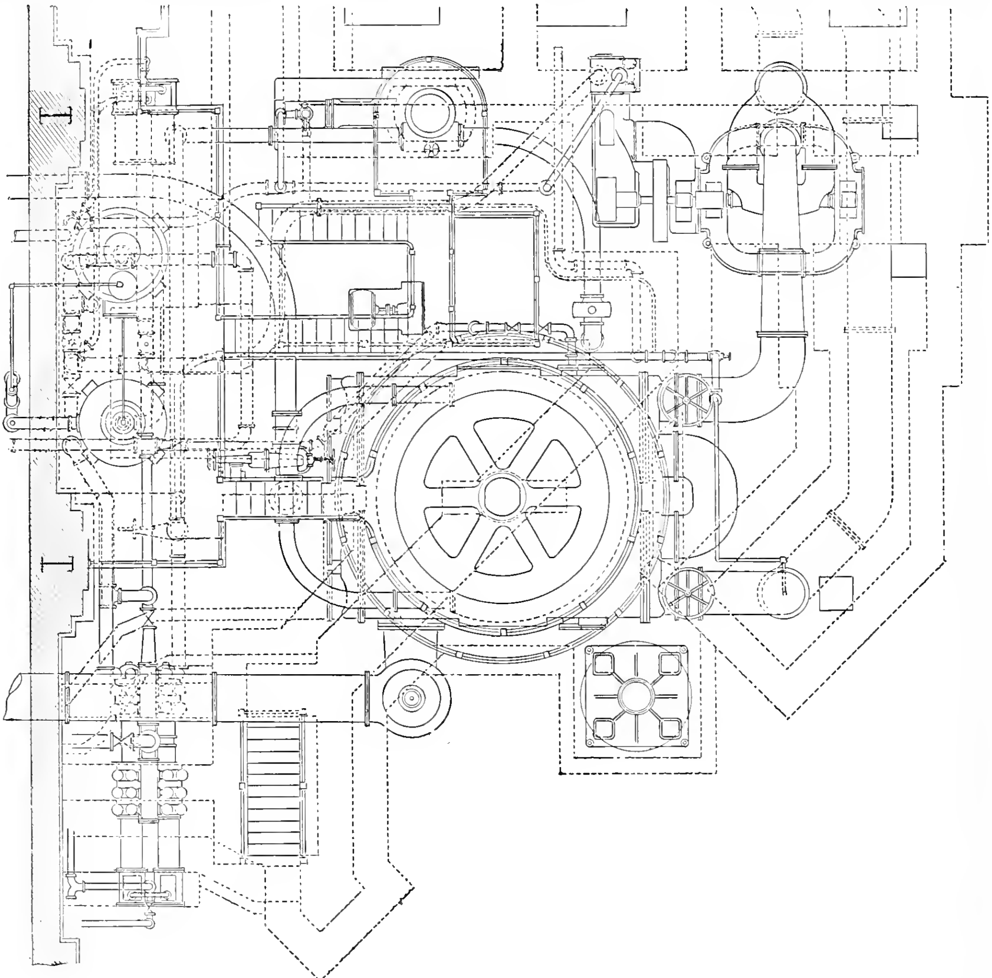

FIG. 5.—PLAN VIEW OF TURBINE UNIT AND AUXILIARY APPARATUS.

From the coal pocket at the side of the old station a belt conveyor is intended to run over the roofs of the turbine and boiler houses for each row of eight boilers that supplies a single turbine unit. Each of the conveyors for this purpose has a belt 20 in. wide, and there will be twelve such conveyors when the proposed turbine station is completed. In front of and above each row of eight boilers the coal bunker into which the conveyor belt empties has a capacity of 44 tons of coal, good for 1½ days' operation at full capacity. From the bunkers this coal passes to Roney stokers with 110 sq. ft. of grate surface per 500-hp boiler. These stokers are driven by induction motors.

All the boilers are of the Babcock & Wilcox water tube type, and each has 152 tubes arranged 14 tubes wide and 18 high. Each tube is 4 in. in outside diameter and 18 ft. long. The tubes of each boiler connect with two 42-in. diameter steam and water drums and the superheater coils occupy a space between the tubes and the under sides of these drums. The tubes and the lower halves of the steam and water drums in each boiler give 5,120 sq. ft. of heating surface, or a little more than 10 sq. ft. of surface per horse-power at a nominal rating of 500 hp per boiler. The hot well for each row of eight boilers is normally nearly empty, and is connected by an automatic valve with the city mains.

The feed water heater for each row of boilers contains 1,600 sq. ft. of coil, is of the National type, and is mounted beside the hot well on the wall of the turbine room near each turbine. Each heater is expected to add 118° to the temperature of the boiler water when it has all of the steam that it can utilize. It is not quite certain at what temperature the water of condensation from the turbines will reach the feed water heaters, but the expectation is that the water will be returned to the boilers with a temperature somewhere between 170° and 200° F. The normal pressure of boiler steam is to be 175 pounds with 150° of superheat. As already pointed out, the circulating pump for condensing water, the boiler feed pumps, the dry vacuum pumps and the oil pumps are all steam-driven, feed water from the 17 by 12 by 15-in. duplex back plunger pump that sits near the turbine. In the dry air pump the 10 by 18-in. steam cylinder is horizontal and the 24 by 18-in. air cylinder is vertical, as this arrangement permits the use of a small fly-wheel. Steam entering this pump is controlled by a throttling governor. To keep water out of this pump, a 10-in. separator is connected between it and the condenser. For handling the condensing water the centrifugal pump at each turbine is of the Worthington volute type, 24-in. size, and is driven by a direct-connected Fleming Harrisburg side crank engine with 15 by 15-in. cylinder, at 200 r.p.m. This engine has a throttling governor.

The circuit of the condensing water through its pump and the condenser forms a syphon, so that the pump is only obliged to give the water a velocity head and to overcome the friction. Though the floor of the turbine room is 16 ft. above mean low tide water, it is estimated that the maximum lift of the pump that handles the condensing water will be less than 10 ft. Each turbine may draw its condensing water from either of the two suction sluices above considered, and this makes it possible to discontinue the use of either of these sluices for the purpose of cleaning or any other reason. The Worthington volute wet vacuum pump is driven by a direct-connected 10-hp motor of the induction type.

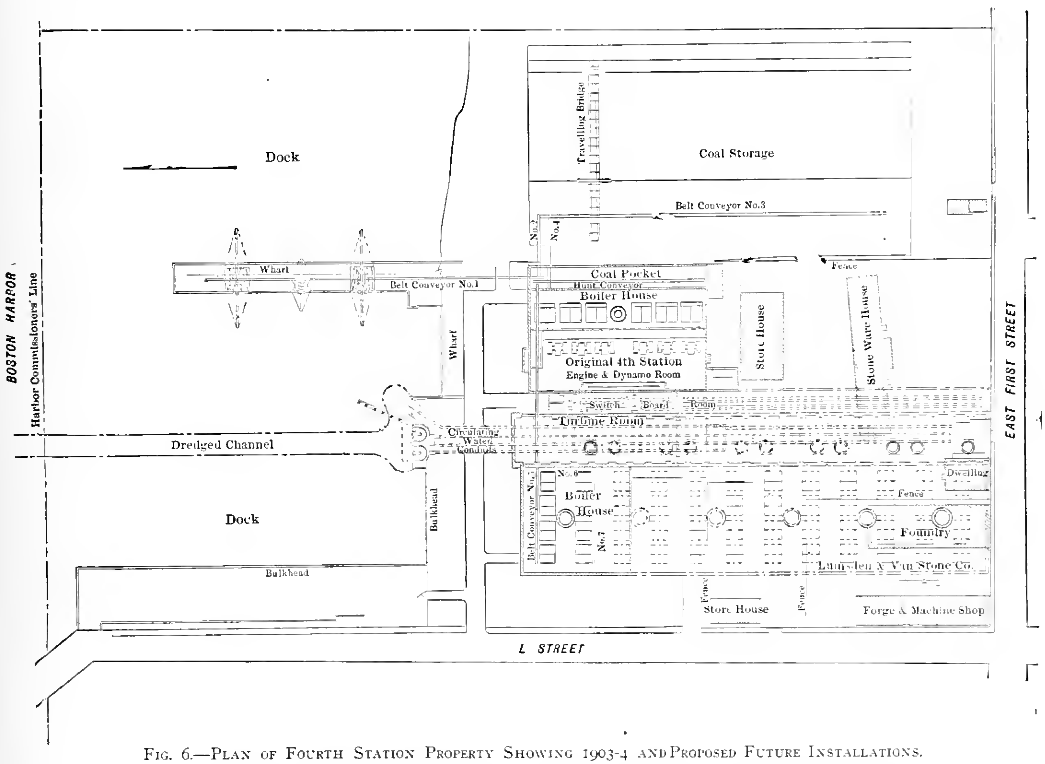

FIG. 6.—PLAN OF FOURTH STATION PROPERTY SHOWING 1903-4 AND PROPOSED FUTURE INSTALLATIONS.

and steam instead of electric drive is used for these pumps because there is not as much exhaust steam available as could be used in the feed water heaters.

No economizers are to be used in this plant, but the gases of combustion from each end group of eight boilers go directly to their chimney through a short iron flue of 8 by 20 ft. cross-section. Each chimney thus receives the gases from 16 boilers through two flues of this size on opposite sides. The number of chimneys for the completed station is thus six, there being one chimney for every two turbine units. Gases from boilers of 8,000 hp nominal rating thus pass to each chimney, which is round in plan with a height of 250 ft. above the foundation, and interior diameters of 18 ft. at the bottom and 16 ft. at the top. These chimneys are constructed by the Alphons Custodis Chimney Construction Company.

The eight boilers that supply steam to each turbine receive their

The steam-driven oil pump that supplies oil for the step bearing of each turbine has cylinders 10 by 2½ by 10 in., and can maintain an oil pressure of 11,000 pounds per sq. in. The oil cylinder of this pump connects with an accumulator that has a 12-in. ram with a 10-ft., 3-in. stroke, and stores 60 gallons of oil, enough to run the step bearing for 10 minutes after the pump stops. At the turbine step the oil pressure is 800 pounds per sq. in.

Each of the 5,000-kw turbo-electric units is of the vertical type, General Electric make, has a weight of 260 tons and stands 29.5 ft. high above the floor. A system of iron stairway and platforms gives ready access to all sides of the turbine. The electric generator of the turbine weighs 82 tons, and the armature alone 42 tons. It has 14 poles and operates at 514 r.p.m., so that the current developed has 60 cycles per second. The Y-connected armature yields 6,900 volts, three-phase. The outside diameter of the generator is 12 ft.

3 in. For maximum exciting current in the magnet coils the required power is 28 kw. or 0.56 of one per cent. of the rated armature output. The exciting current for the turbine generators is supplied at 125 volts, and for the present will be drawn from dynamos in the old station by way of the operating room in the switch house. In each turbine room the great Niles crane that sweeps over all of the equipment is entirely motor-driven and has a lifting capacity of fifty tons.

From each turbine generator the 6,900-volt, three-phase current passes to a pair of 800-amp., 15,000-volt oil switches on the second floor of the switch house, and through these switches to double sets

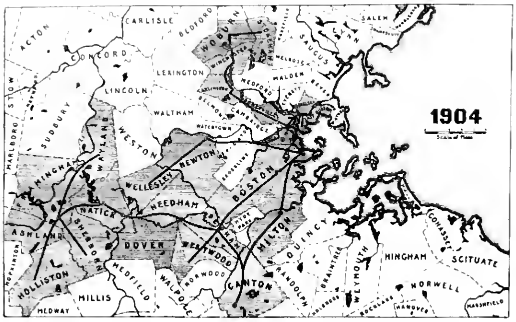

FIG. 7.—MAP OF BOSTON EDISON LIGHTING AREA, 1904.

of three-conductor bus-bars in brick and stone compartments on the floor below. On these bus-bars each connection between a cable and its bar is contained in a separate compartment. Some of the transmission lines to the distant towns supplied by the Edison system are connected to these 6,900-volt bus-bars through 15,000-volt, 300-amp. oil switches. For some of the other transmission lines a voltage of 4,600 is desired, and double sets of three-phase bus-bars of this voltage are, accordingly, mounted in compartments like those for the 6,900-volt bars. In order to obtain the 4,600-volt current and also the 6,900-volt current while the turbine plant has been under construction, transformers have been resorted to. These transformers draw their energy from the main generators in the old L Street station, which operate at 2,300 volts, 60 cycles, three-phase. Space for the transformers in question has been provided by a building at the rear of the old station.

This building is a one-story structure of brick, steel and concrete, with the transformers in the main room and air chambers underneath. In this building there are at present six air-blast transformers of the General Electric make. Each of three of these transformers is rated at 900 kw and has a ratio of three to one between primary and secondary windings, so that with 2,300-volt current from the old generators at the L Street station, a current of 6,900 volts can be delivered to the bus-bars in the switch house. The other group of three transformers have a capacity of 500 kw each, and change the current from 2,300 to 7,960-2,650 volts, from which the pressure of 4,600 volts for the bus-bars can be obtained by suitable connections. Two blowers each driven by a 5-hp, 6-amp., 550-volt induction motor are used to maintain the air pressure in the chamber under the transformers.

The 900-kw transformers are connected to the high-voltage bus-bars through 15,000-volt, 500-amp. oil switches, and the 500-kw transformers are so connected through 15,000-volt, 300-amp. oil switches. To connect the primary windings of the 900-kw transformers with the 2,300-volt bus-bars of the old generators, two 1,200-amp., 2,300-volt oil switches are employed. From the 4,600 and 6,900-volt bus-bars at the L Street station energy is transmitted to the various sub-stations of the Edison system.

Though the design of the new station at L Street contemplates its ultimate extension, so as to include a generating capacity of 60,000 kw, the present structure is of much smaller capacity. The turbine room now nearing completion covers one-third of the area for which the entire turbine house is designed, and provides room for four of the 5,000-kw turbine units. Present plans, however, call for the installation of only two of these turbine generators. Following the present equipment of the turbine room the boiler house has been constructed so as to allow the erection of two rows of boilers, sixteen in all, connected with a single chimney.

These equipments give the new turbine plant a generating capacity of 10,000 kw, and a little more than double the capacity of the L Street station. At this point it is interesting to note the rise in generating capacity of the Boston Edison system. The first station of this system was a rented building located between Bumstead Court and Head Place, and contained at the start a Babcock & Wilcox boiler rated at 200 hp, one 90-hp Armington & Sims engine and two Edison dynamos, type H, of about 400 16-cp lamp capacity each. On the basis of 4 watts per candle-power the kilowatt rating of each of these dynamos would have been 25.6 and 51.2 kw for the pair. This station was first started on February 20, 1886. The equipment at this station was soon increased by the addition of other boilers, similar engines and four type H and two type S Edison dynamos, so that it had a capacity of 2,400 16-cp lamps, or 153.6 kw on the 4 watts per candle-power basis in the H dynamos before the end of

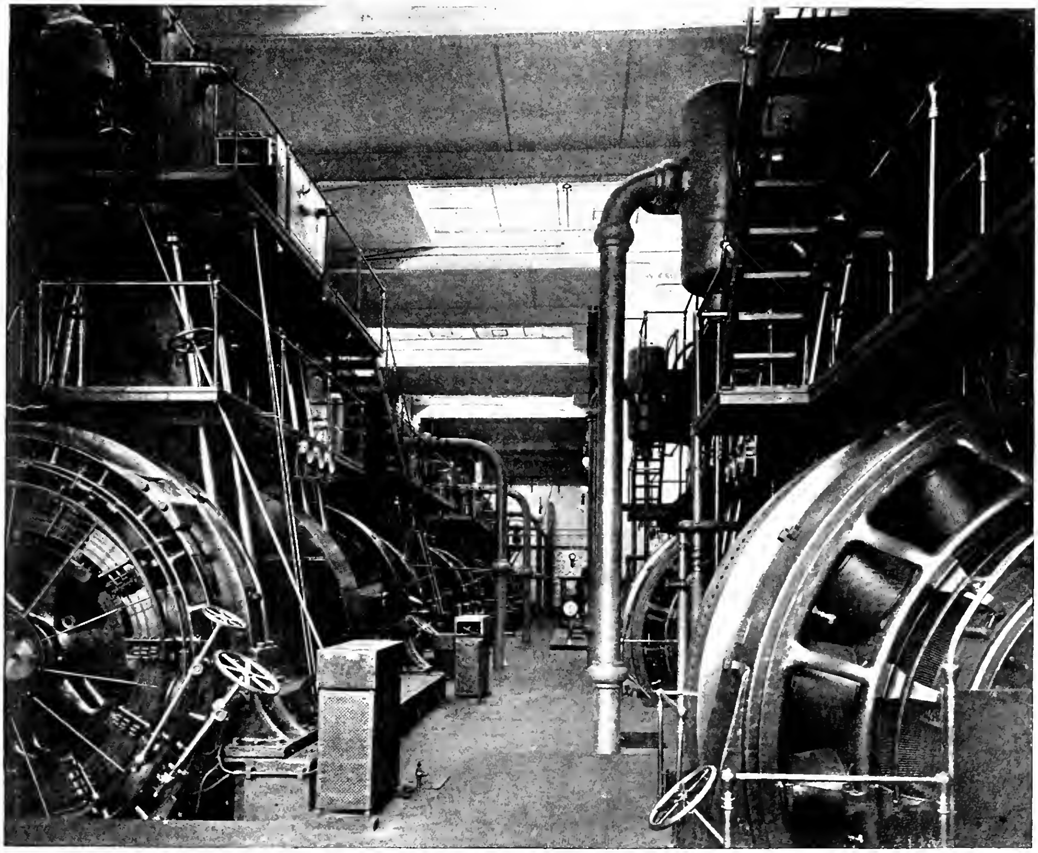

Fig. 18.—View in the Old Engine Room, Boston Edison Atlantic Avenue Station.

the year in which it was started. Even this rapid increase was not sufficient to meet the growing demand for electric light, and a new two-story brick station, 50 by 70 ft. in ground area was erected adjoining the old one in the early months of 1887. This new station was designed for twenty Armington & Sims engines of 150 hp each, and forty Edison No. 20 bipolar dynamos. Two of these dynamos were belted to each engine, and were operated in series on the three-wire system, with approximately 250 volts on the outside wires. This station was started in June, 1887, with seven of the engines and fourteen of the dynamos just named. Rating these fourteen dynamos at 60 kw each gives the capacity of the new station as 840 kw at the start.

In order to reach the north end of the city a second station was built shortly after the first and consisted of a two-story brick building with a ground area 164 ft. deep between Hawkins and Bowker Streets, and a frontage of 38 ft. 3 in. on the former and 15 ft. 3 in. on the latter. This second station was started on December 21, 1887, with an equipment of two Heine boilers, one of 200 and the other of 400 hp, four Armington & Sims high-speed engines of 150 hp each, like those at the first station, and eight of the No. 20 Edison dynamos belted in pairs to the engines. At 60 kw each the rating of these eight dynamos would amount to 480 kw, and this added to the capacity at the first station gives a total of 1,320 kw for all the dynamos of the system on the date last named. This second station was designed for an ultimate equipment of 12 of the 150-hp engines and 24 of the 60-kw dynamos, which with the 40 dynamos that could be installed at the first station would give a total equipment of 64 of these 60-kw dynamos.

This limit to the generating capacity of both the second and third stations was reached before the middle of 1891, when 64 dynamos had all been installed, giving a capacity of 3,840 kw. A third generating station was then seen to be necessary and a site on the harbor front at the foot of Pearl Street, between Atlantic Avenue and the water was selected. This site had the advantages not possessed by the first and second stations, of sea water for condensing purposes, and of the direct delivery of coal from vessels. Ground was broken for the third or Atlantic Avenue station on October 10, 1891, on the site just mentioned where English tea ships were unloaded free of charge almost 118 years earlier; that is, on December 16, 1773. This third station began operation in the latter half of 1892, and in its equipment as in its location it differed much from the two earlier plants. The boilers were all of the Babcock & Wilcox water tube type, and each had a water heating surface of 3,680 sq. ft. and was rated at 368 hp. Instead of small horizontal, high-

FIG. 19.—SWITCH HOUSE, THIRD STATION.

speed, simple, non-condensing, belted engines, like those at the first and second stations, the engines at the third station were of the large slow-speed, vertical, triple-expansion, condensing, direct-connected type.

Each of the first four engines installed at this third station had three vertical cylinders, carried a dynamo at each end of its shaft, and was rated at 660 hp with 120 r.p.m. and 160 pounds steam pressure. These engines were built by the J. Morgan Poole Company. Two multipolar dynamos were connected at opposite ends of the shaft at each of these four engines. Each dynamo was of Edison General Electric make, had 14 poles, was rated at 200 kw, and developed continuous current at 160 volts. This voltage of 160 for the dynamos at the Atlantic Avenue station was adopted in order to provide for the loss of pressure in the feeders between this station and the greater part of the service area of the Edison system at that time.

These eight dynamos of 200 kw each added a generating capacity

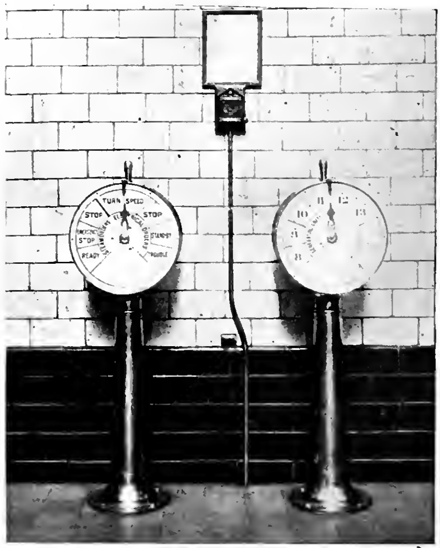

FIG. 20.—CONTROL DIALS, THIRD STATION.

of 1,600 kw to the Edison system, and brought the combined capacity of the three stations up to 5,440 kw, in 1892. This equipment, with the aid of storage batteries served to carry the increasing load of the Edison system until the year ending at the middle of 1896, during which a fifth vertical engine with two direct-connected generators was added at the third station. This engine was of the McIntosh & Seymour make, cross compound, condensing and rated at 1,200 hp with 100 r.p.m., and 160 pounds steam pressure. Each end of the shaft of this engine carries the armature of a 12-pole, 400-kw, 160-volt, continuous dynamo of General Electric make. These two dynamos brought the generating capacity of the three Edison stations up to 6,240 kw in 1896.

By 1899 another increase in generating capacity was necessary and this was made by the addition of two vertical engines, each direct-connected to a single multipolar dynamo. These engines are also of the McIntosh & Seymour make, cross compound, condensing, each rated at 1,200 hp with 160 pounds steam pressure and 100 r.p.m., and are located in the original engine room at the third station. Unlike the first five engines at that station, the two under consideration, numbered 6 and 7, carry only one generator, and this generator is mounted between the main bearings instead of at the end of the shaft. The two generators connected to Nos. 6 and 7 engines were made by the General Electric Company, and each is rated at 800 kw and 300 volts, continuous current.

These 300-volt generators, unlike the other ten in the old engine room of the third station, are each connected to only the outside wires of the three-wire system. Ballancing of the load on the two sides of the system is thus left to the other generators. The two dynamos driven by each of the first five engines at the third station are connected in series with their common terminal on the neutral wire of the system, and the other two poles of these two dynamos are connected respectively to the positive and negative wires, just as is the case with the pairs of bipolar dynamos belted to single engines at the first and second stations. By the two 800-kw dynamos the generating capacity of the three stations was increased to 7,720 kw, in 1899, deducting 120 kw for the capacity of two of the 60-kw bipolar dynamos that had been taken for use as a motor-generator. Even this capacity was seen to be inadequate, especially as it was no longer desirable to operate the simple non-condensing engines at the first and second stations, and an extension of the third station building was begun in March, 1900, and completed the following year.

The old engine room at the third station had an area of 60 by 160 ft., including the switchboard room, which was 70 by 126 ft. in area. In this old engine room the 12 direct-connected generators have a combined capacity of 4,000 kw. For the new engine room at this station the ground area is about 150 by 85 ft., and the intended equipment is six direct-connected units of 1,600-kw capacity each. These figures for areas do not include the boiler room. Two of the generating units just named were installed in 1901, and two more have since been added. Each of these units consists of a McIntosh & Seymour vertical engine direct-connected to a General Electric generator mounted between the main bearings.

The engines are rated at 2,400 hp each with 160 pounds steam pressure and 100 r.p.m. All four engines are cross compound and they exhaust into a common condenser pipe of 50 in. diameter that extends entirely around the new engine room. The 1,600-kw generator driven by each of these engines operates at a maximum voltage of 300, and delivers continuous current to the outside wires of the three-wire system. One of these generators is designed to deliver both alternating and continuous current, has 30 poles and at 100 r.p.m. develops 184 volts alternating, six-phase, at 25 cycles per second. It was the intention when this generator was installed to use step-up transformers with it and obtain a high voltage for transmission to sub-stations, but the purchase of the L Street station of the Boston Electric Light Company shortly thereafter made it unnecessary to carry out this plan. With generators of 4,000 kw total capacity in the old engine room of the Atlantic Avenue station, and generators of 6,400 kw in the new engine room the total capacity there amounts to 10,400 kw. The old bipolar dynamos of 3,720-kw capacity, more or less, at the first and second stations can hardly be considered live generating apparatus at this date, but probably some of them could be put into service in case of a break-down at other stations.

Boilers at the third station have been increased in number as engines were added from time to time until now there are fifteen, all of the Babcock & Wilcox water tube type. Seven of these boilers contain 3,680 sq. ft. of water heating surface each, and the remaining eight each have 4,181 sq. ft. of such surface. In 1901 the sale of all the assets of the Boston Electric Light Company to the Edison Electric Illuminating Company brought the L Street station in South Boston to the latter company. This station was built in 1898 at the water front, as previously mentioned, on land formerly occupied by the Harrison Loring shipyard. In ground area the original L Street station, including the boiler room and coal pocket measures 174 by 244 ft. The boiler room is separated from the engine room by a brick wall and contains 12 Babcock & Wilcox boilers set in six batteries. Each of these boilers has a nominal rating of 500 hp and operates at 160 pounds as a standard pressure. In the engine room there are six vertical cross compound condensing engines of the McIntosh & Seymour make, each rated at 2,350 hp, with 160 pounds steam pressure and 120 r.p.m. Between the main bearings of each of these engines there is mounted a General Electric alternator with a rotating magnet frame of 60 poles.

Each alternator is rated at 1,500 kw and 2,250 volts, three-phase and 60-cycle. These six main generators supply current to 23 motor-generator sets located in the same room and also operate the transformers already mentioned that step up to 6,900 and 4,600 volts for the transmission lines, besides delivering energy to the distribution system in Boston at 2,250 volts. In these six alternators there is a combined capacity of 9,000 kw, and with the 10,400 kw of generator capacity at the Atlantic Avenue station the Edison system has at the present time 19,400 kw of main generators in position. This takes no account of the old bipolar dynamos at the first and second stations. The two 5,000-kw turbine alternators to be installed at the new L Street station will thus raise the capacity of live generating apparatus at L Street and Atlantic Avenue to 29,400 kw.

This rise of generating equipment from the two 25-kw dynamos of 1886 has been brought about by the increase of connected loads, the purchase of other lighting systems, and by transmission of energy to towns and cities distant in some cases more than 25 miles from either of the generating stations. At the middle of 1887, about 16 months after the little plant at Head Place began to operate, it was supplying current to 8,500 incandescent lamps on the premises of 200 customers, and to 80 electric motors with a total rated capacity of 250 hp. At the middle of 1901, before the purchase of the Boston Electric Light system had been completed, the circuits of the Edison Company were connected to 2,503 arc lamps, 247,935 incandescent lamps and to 2,621 motors with an aggregate rating of 10,651 hp. On the same date the Boston Electric Light system was operating 4,913 arc lamps, 112,636 incandescent lamps and 1,849 motors with an aggregate rating of 5,408 hp. The absorption of the Boston system and the growth of another year brought the load on Edison circuits at June 30, 1902, up to 442,034 incandescent lamps, 4,913 arc lamps and 18,621 hp in capacity of connected motors. Since the date last named the purchase by the Edison Company of a number of electric lighting systems in cities and towns within a radius of 25 miles from Boston, aided by the growth of business in that city, has given its lines a connected load of 681,162 incandescent lamps, 9,803 arc lamps and 24,225 hp in capacity of connected motors. All of the loads combined represent an equipment of 1,152,379 incandescent lamps of 16 cp each.

Veto of Niagara Power Bill.

Governor Odell, of New York, has vetoed the bill of Assemblyman Thompson enlarging the scope and powers of the Niagara, Lockport & Ontario Power Company. In his memorandum the Governor says that, while the bill is desired by the immediate locality concerned, he is convinced that throughout the State it is almost universally disapproved. He summarizes the history of the corporation since 1894, when the company was chartered by special act "to furnish pure and wholesome water for domestic purposes to the City of Lockport, as well as to generate and sell electricity in the Counties of Niagara, Orleans and Erie," and remarks that the time in which work was to have begun has about elapsed "without advantage having been taken of the valuable rights conferred by the original act." It is now proposed, he points out, to eliminate the water supply feature and extend to all the counties of the State the right to sell electric and hydraulic power, with very broad powers of condemnation and few restrictions or safeguards, and without in any way exacting compensation. There is nothing, he says, to prevent the sale of this charter to a competing company, and therefore competition is not assured.

"The plea that other corporations are enjoying similar privileges to those which this bill seeks to bestow is no justification," the Governor says, "for the continuance of policies which dissipate the rights of either the State or the municipalities. That governmental policy which does not respect the expressed will of our citizens in relation to both safeguarding their rights and exacting compensation for them is sure to meet with just criticism and disapproval.

"That these privileges are valuable is beyond question, and that the State has the right to demand a proper recompense for them, therefore, should never be lost sight of. That this proposed act does not take cognizance of these facts makes it, in my mind, undesirable legislation."

Governor Odell calls attention to the widespread solicitude, expressed in protests from all over the Union, as to peril to the beauty of Niagara Falls. On the question of threatened damage to the falls, he says, there is wide difference of opinion. "If the result, however, would be less harmful," says the Governor, "than those who seek for the preservation of the falls believe, it certainly would lead, or rather, be an excuse for other companies that would in the end produce the results which are feared. The Legislature should protect the falls, rather than increase the menace to which I have referred, by restricting those corporations which are already in possession, by compelling the removal of obstructions and unsightly structures which mar the beauty of Niagara."

Municipal Plant to Be Sold.

News from the west states that another town has become tired of municipal ownership. The electric lighting plant, located in and owned by the city of Leon, Iowa, has been offered for sale. Leon is the county seat of Decatur County and has a population of 2,000.

Some Aspects of New England Central Station Development.

UNDERGROUND CABLES AND CONDUITS IN NEW ENGLAND.

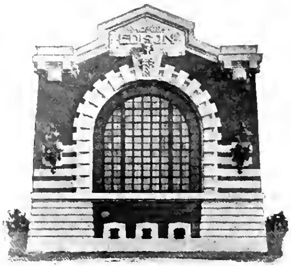

FIG. 1.—WINDOW BOSTON EDISON STATION.

EDISON tubes made up the first underground conduits and conductors in Massachusetts, and probably in New England. The five Edison companies in Massachusetts were early in the field, the Lawrence company having been incorporated in 1882, the Fall River and the Brockton companies in 1883, the New Bedford company in 1884, and the Boston company in 1885. All of these companies except that at Brockton appear to have installed underground tubes at the start, but in that city all of the electric light wires seem to have been overhead prior to the year ending on June 30, 1890.

On June 30, 1888, the Edison company at Boston had 64,530 ft., at Fall River 7,949 ft., and at Lawrence 7,000 ft. of underground tubes or conduits. For the Boston and Fall River companies the respective lengths of wire in conduits were exactly three times the lengths of these conduits, showing clearly the use of three-wire Edison tubes. At Lawrence, however, the length of wire in conduits was 41,347, showing that some conduit other than three-wire tubes was used. Though figures for the conduits of the New Bedford Edison Company are not available for the date last named, a part of the circuits there were no doubt underground, and the length of three-wire tubes on June 30, 1889, was 7,200 ft. Aside from the Edison systems just considered, the only underground electric lighting circuits in Massachusetts during 1888 were those at Pittsfield and Springfield, and the Pittsfield circuits were discontinued during the following year. The underground wires at Pittsfield measured 47,100 ft. on June 30, 1888, and belonged to the Pittsfield Illuminating Company, which operated Westinghouse dynamos. These dynamos were probably alternators of 1,000 volts, and this would indicate that the underground circuits were operated at the same pressure. As these circuits were discontinued during the following year, it is a fair presumption that their insulation gave way.

At Springfield the underground circuits were made up of single-conductor, rubber-insulated, lead-covered cables laid in wooden conduits or boxes and connected to 1,000-volt Westinghouse alternators. On June 30, 1888, the length of these conduits in Springfield was 4,700 ft., and the length of conductors therein was 29,000 ft. Unlike Pittsfield, the underground circuits at Springfield have been maintained and greatly extended, so that on June 30, 1903, the total length of conduits there was 101,385 ft., and they contained 518,992 ft. of wire. These wires varied in size from No. 8 to cables of 500,000 cm. cross section. Meantime the voltage on the underground circuits has been raised and varied so that they now operate at 2,500, 6,000 and 10,000 volts respectively. The present cables are of both the single-conductor and duplex types, and all are rubber-insulated and lead-covered. Cables operating at 10,000 volts carry direct current for arc lighting, and have one conductor each. Duplex cables carry 60-cycle, two-phase alternating currents, some at 2,500 volts for distribution from the sub-station, and others at 6,000 volts to complete the transmissions between the water power plants on the Chicopee River and the sub-station.

The rubber insulation on each conductor of the 10,000-volt cables is 7/32 in. thick, and is covered with a 5/64-in. sheath of lead. On each conductor of the 2,500-volt cable the rubber is 7/64 in. thick, and the lead outside of both conductors has a thickness of 3/32 in. The 6,000-volt cable has a rubber cover of 1/4 in. on each conductor, and 3/32 in. of lead over the pair. All of the later underground construction has been with vitrified clay conduits in lengths of 18 in., and laid in beds of concrete 4 in. thick on top, bottom and sides. In these clay conduits each single duct has a 3-in. circular opening, and each multiple duct has a 4-in. square opening. Single ducts were so laid as to break end joints, were given 1/4 in. of cement mortar between layers and about each joint of multiple ducts a strip of burlap 6 in. wide was placed after having been dipped in hot coal tar or neat Portland cement. The depth of trench in each case was such that the top of the layer of concrete over the ducts is 18 in. below the surface of the street.

In 1900 the population of Springfield was 62,059, so that it stood ninth among the cities of the State in this respect, but in the lengths of its underground cables and conduits it ranks next to Worcester and Boston. Until the year ending June 30, 1895, during which the Boston Electric Light Company and also the Brookline and Suburban Companies in that city laid considerable lengths of underground conduits, the Springfield system and the five Edison plants were the only ones in Massachusetts that maintained more than trifling lengths of electric light conductors underground. It thus appears that, with the single exception of the Springfield system, the Edison plants were more than a decade ahead of all others in the State in the construction of underground circuits.

Of course, a ready explanation of the priority of the Edison plants in underground work rests partly on the low voltage of 250 to 300, which has been maintained from first to last between the outside conductors of their three-wire distribution systems. This explanation brings out more clearly the enterprise of the managers of the Springfield system, in which alternating current of 1,000 volts was distributed through an extensive set of underground cables during seven or eight years before any successful attempt on a large scale was made elsewhere in the State to operate underground circuits of more than 300 volts.

FIG. 2.—UNDERGROUND CONDUITS, SPRINGFIELD, MASS.

The figures for underground conductors in the electric lighting systems of Massachusetts on June 30, 1894, are interesting on this point. Aside from the five Edison systems above considered, the only lighting plants with underground wires in the State, and the lengths of these wires, were the Springfield with 67,272 ft., the Brookline with 1,000 ft., the Pittsfield with 1,000 ft., the Great Barrington with 450 ft., and the Winchendon with 198 ft.

Since June 30, 1895, when the Boston Electric Light Company had 387,806 ft., the Suburban company, of Boston, 9,656 ft., and the Brookline company 14,872 ft. of wire underground, the installation of underground conduits and cables has gone rapidly forward in some cities of Massachusetts. During the following year the Boston Electric Light Company increased its length of underground wires to 942,582 ft., and 25,000 ft. of wire was put into an equal length of underground conduit in the town of Lenox. At that time the Boston Electric Light Company was operating direct-current power circuits of about 500 volts, constant-current circuits from arc dynamos that probably ranged from 2,500 to 10,000 volts, and circuits with alternating current at 1,000 or 2,000 volts. It is probable that parts of all these circuits were included in the underground work. In the Lenox underground system alternating current, probably single-phase at 1,000 volts, appears to have been used. Both the Suburban and the Brookline companies, like the Boston, were distributing 500-volt direct current for motors, constant current from arc dynamos, and alternating current for incandescent lighting, but it cannot be stated here which of these classes of service first went underground.

During the year ending June 30, 1897, the Worcester Electric Light Company brought the length of its underground conduits, which had been started during the previous year, up to 12,554 ft. On June 30, 1898, the length of wires that had been installed in the underground conduits of Worcester was 243,266 ft. At that time the Worcester company was operating 500-volt power circuits, constant-current circuits from arc dynamos, and circuits with alternating current of probably about 2,000 volts.

The next important addition to the group of lighting systems with underground conduits in Massachusetts was that at Lowell, where 8,206 ft. of wire were laid in 1,364 ft. of conduit during the year ending June 30, 1901. At that date the Lowell company was operating 500-volt power generators, constant-current arc dynamos, and 2,200-volt alternators. The Suburban company, of Boston, appears to have reached its maximum length of underground wires, 18,924 ft., during the year ending June 30, 1898, and from this date until

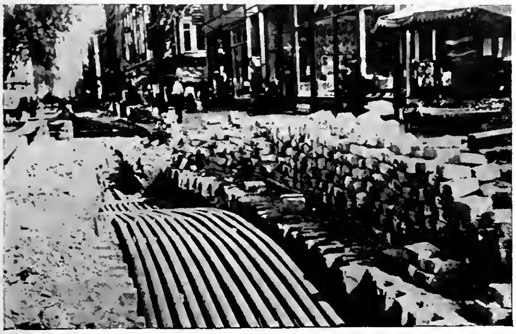

FIG. 3.—CROSSING A BRIDGE IN LOWELL WITH CABLES IN IRON PIPES.

the sale of its assets to the Boston Edison Company, on December 31, 1901, there was a decline in the length of these wires.

On February 28, 1902, the transfer of all the property of the Boston Electric Light Company to the Boston Edison Company was completed. On June 30, 1901, the former of these companies had installed 4,198,961 ft. of wire in 304,874 ft. of underground conduit. At the same date the wires of the Boston Edison Company, all underground, measured 2,029,583 ft. in 497,417 ft. of conduit. During the year ending June 30, 1899, the Malden Electric Company laid 1,200 ft. of wire in 1,000 ft. of underground conduit, but this wire seems to have been discontinued before June 30, 1902. During the year ending at the date just named the Suburban Company, of Revere, laid 6,400 ft. of wire in an equal length of underground conduits, and this remained the same a year later. This company operates with 2,300-volt alternators and 9,000-volt constant-current transformers. During the year ending June 30, 1891, the Pittsfield Electric Company laid 1,000 ft. of wire in 500 ft. of underground conduit, and the wire increased to 2,150 ft. on June 30, 1897, but had declined to 946 ft. on the corresponding day of 1904.

The Church Green plant, a system distributing direct current at about 110 or 220 volts in a small part of Boston, had laid 16,755 ft. of wire in underground conduits by June 30, 1897, but on the like day of 1902 this length had shrunk to 10,755 ft., and the system was sold to the Boston Edison Company on May 1, 1903. On June 30, 1903, the electric system at Winchendon, above noted, had increased its length of underground wires to 1,704 ft. in the same length of conduit. The Leominster plant had 150 ft. of wire underground at the date just named. In the electric system at Lynn 6,565 ft. of wire was put underground during the year ending June 30, 1902, and in the following year the length was increased to 10,618 ft. At Lenox the lengths of wires and conduits alike had increased to 51,023 ft. at the middle of 1903.

The larger electric lighting systems of the State had lengths of wires in underground conduits as follows on June 30, 1903:

Company.	Feet of conduit.	Feet of wire.
Boston Edison	876,315	6,592,181
Worcester	185,261	1,895,939
United (Springfield)	101,385	518,992
Fall River (Edison)	46,091	261,563
Brookline	26,686	84,776
New Bedford Edison	24,223	146,877
Lowell	21,050	115,525
Brockton Edison	18,503	68,364
Lawrence (Edison)	13,890	59,490

Each of the five Edison systems of the State has been consolidated with or has absorbed another competing system; but it seems that outside of Boston these other systems had no underground circuits. In New Bedford and Fall River at least, and probably in all of the other Edison plants, many of the original iron tubes buried twenty years ago are still doing regular service. In Lawrence the use of Edison underground tubes seems to have declined, for the greatest length of wires in conduits there was 72,797 ft., reached by the middle of 1891, with 7,200 ft. of conduit. Another decline in the extent of an Edison underground system is that at Brockton, where a length of 34,534 ft. of conduit and 123,903 ft. of wire therein was installed by the middle of 1894, but had shrunk as indicated by the table, in 1903.

In July, 1890, the Edison company, of New Bedford, was consolidated with the local gas company, which also did electric lighting, and at that time the Edison system included 24,000 ft. of wire in 8,000 ft. of underground conduit. At the time of the consolidation the gas company had no underground lines, but since that date the length of wires in conduits has been extended as indicated in the table. A part of the increase seems to have been made with Edison tubes, and a part with clay ducts.

On July 1, 1896, the Fall River Electric Light Company purchased the entire plant of the local Edison system, which then included 104,040 ft. of wire in 26,963 ft. of conduit. The purchasing company had no underground circuits at that time, but since then the length of wire in conduits has more than doubled. The increase of underground lines has been divided between Edison tubes and clay ducts, but future extensions will be made mainly with the latter.

As above noted, the length of underground wires in the system of the Boston Electric Light Company at the time of its absorption by the Boston Edison was more than 4,000,000 ft., and it follows that more than 60 per cent. of the wire shown in the table for the Boston Edison Company was derived from the Boston Electric system. As this latter system contained no Edison tubes, these tubes now carry less than four-tenths of the underground circuits of the Boston Edison Company.

The actual percentage of the wires of this company that are in Edison tubes must in fact be much below 40 per cent., for a large amount of clay conduit has been laid by it. The later practice in the Boston Edison system has been to lay all feeders with lead-covered cables in conduits, devoting the Edison tubes to mains and service taps. In May, 1901, before consolidation with the Boston Electric system the Edison system there included 301,329 ft. of tubes used as mains with conductors that varied in size from 200,000 to 350,000 cm., and 127,000 ft. of tubes used as feeders and containing 1,000,000-cm. conductors, all of these tubes being three-wire. There was also 17,000 ft. of tube used for the lines between the several stations and sub-stations. This gives a total of 428,329 ft. of Edison tube containing 1,284,987 ft. of conductors in use for mains and feeders. At the same time the Edison system contained 145,000 ft. of 1,000,000-cm., 35,000 ft. of 350,000-cm. cable, also 1,000 ft. of 12-conductor and 63,000 ft. of 3-conductor cable, all laid in conduits. The entire length of these cables was thus 449,000 ft. Most of this cable was insulated with rubber, but a part with paper, and 80,000 ft. of cement-lined iron duct and 371,000 ft. of clay duct were in use to carry the cables.

Between the L Street generating plant of the Boston Edison system and the sub-stations at Newton, Somerville, Woburn, Dedham, Milton and Natick, that are to distribute current in eighteen cities and towns within thirty miles of Boston, the transmission lines consist in part of underground cables. The completed length of these cables is 115,000 ft., and they are all laid in 3-in. vitrified clay conduit. Each cable carries three No. 4/0 copper wires insulated with paper and covered outside with a lead sheath that is 1/10 in. thick.

About each conductor the paper is 3/16 in. thick, the spaces between the three conductors of each cable are filled with jute, and outside of the three conductors, next to the lead sheath, there is another 3/16-in. layer of paper. These cables carry three-phase, 60-cycle current at 6,900 volts. Since June 30, 1903, the electric light and power circuits in the central part of the business section of Lowell have all been put underground. This has largely increased the lengths of cable shown for the Lowell Company in the above table, but the length of conduit is about the same. In its present state the Lowell system includes about fifty miles of cables that vary in size from duplex No. 10 pressure wires to conductors of 500,000 cm. The cable is laid in tile conduits, as a rule, is mostly rubber-insulated, and is lead-covered. Much of this cable distributes 22,000-volt alternating current, and many of the transformers are in street manholes, from which secondary circuits of 110 volts are carried. At one point where the cables cross a bridge under its paving they are carried in iron pipes to save room. In Lowell the conduit system is continuous from the generating station on the bank of the Concord River to the business section.

At Providence, R. I., the Narragansett Electric Light Company began to put its wires underground in 1899, and since that time vitrified clay conduits have been laid in more than forty miles of streets. These conduits contain more than 1,700,000 ft. of ducts, of which about 700,000 ft. are in the multiple-duct form, and over 1,000,000 ft. are single-duct. Upwards of 850 manholes give access to the duct system, the standard size of each being 7 by 7 ft. square and 8 ft. deep. In front of the battery sub-station of the system there is a great manhole 21 ft. long, 8½ ft. wide and 9 ft. deep. Some of the manholes extend below the water level in Narragansett Bay, and it was necessary to make them water-proof with linings of tar paper put on with hot asphalt and then a layer of cement concrete. In junction manholes fuses connect the cables so that a defective section may be readily located.

All of the cables in these conduits are rubber-insulated and lead-covered, and all conductors larger than No. 6 B. & S. gauge are stranded. These cables carry voltages of 250 to 500 on a three-wire system, constant current for arc lighting at voltages up to 6,500 volts, 2,300-volt alternating current, and 11,000 volts on the transmission lines to the sub-stations at Warren and Warwick. For 500 volts and under the thickness of rubber insulation on cables is 5/32 in. The cables for 2,300 volts and for constant current up to 6,500 volts have rubber 7/32 in. thick on each conductor, and on the 11,000-volt cables the thickness of rubber is 9/32 in. There are four miles of this 11,000-volt cable in the conduits, and it connects with 800 ft. of armored cable that crosses the Seekonk River. In size of conductors the underground cables range from No. 14 to 1,000,000 cm. and their total length is 1,468,200 ft., or 278.06 miles. There is also 5,000 ft. of the armored submarine cable used with currents of the several voltages, used mainly in crossing the river to East Providence. Starting from the generating station on South Street at the water front the underground cables cover the entire central business section of the city and run out into the residence portion.

ELECTRIC TRANSMISSION FROM CITIES IN NEW ENGLAND.

Transmission of energy from water powers to distant cities has justly received much attention, but another important branch of transmission has sprung up without attracting much notice. This is the transmission from comparatively large cities to smaller and distant places. By such transmissions the populations and especially the areas supplied by single electric systems have been much extended within the period since 1890. In Massachusetts the electric supply systems of Boston, Cambridge, Haverhill, Lawrence, Lowell, Lynn, Malden, Marlboro, New Bedford, Springfield and North Adams, besides those of a number of smaller places now extend to other cities or towns. From the new generating station in Cambridge current of 2,300 volts, 60 cycles, three-phase is transmitted to Belmont, an adjoining town. In the towns of North Andover and Methuen, which bound the city of Lawrence on two sides, both public and commercial lighting is supplied directly from the water power station of the electric company in that city. The arc lamps used to light the streets in these towns are on series circuits, and commercial incandescent lamps are supplied through transformers on circuits of about 2,200 volts.

From the steam power station on the river bank in Lowell electric current is transmitted to the towns of Billerica, Tewksbury and Andover, all three within a ten-mile radius. The series incandescent street lamps in Billerica are controlled by a regulating transformer at the Billerica end of a 2,200-volt line from the bus-bars at the station. Commercial service in this town is also furnished through transformers on the 2,200-volt line. In Tewksbury incandescent street lamps are operated on a series circuit. For the transmission to Andover the 2,200-volt current at the Lowell station is raised by a transformer to 6,600 volts, and this pressure is reduced to 2,200 volts at the Andover end for distribution there. A part of this 2,200-volt current goes to a constant-current transformer in Andover for the operation of series arc and incandescent street lamps. In the town of Groveland, across the river from Haverhill, series incandescent street lamps are operated from the steam-driven electric station on the bank of the Merrimac in that city.

Four cities, Malden, Everett, Medford and Melrose, are all supplied with street and commercial lighting direct from a generating plant using steam power, in the former. These cities form a rather compact area of about six miles north and south, and a like distance east and west. Circuits of series arc and incandescent street lamps in all four cities are connected to constant-current transformers at the generating station in Malden. Commercial lighting and power is distributed in these cities from 2,200-volt circuits that also run back to the generating plant. Southboro, a town that adjoins Marlboro,

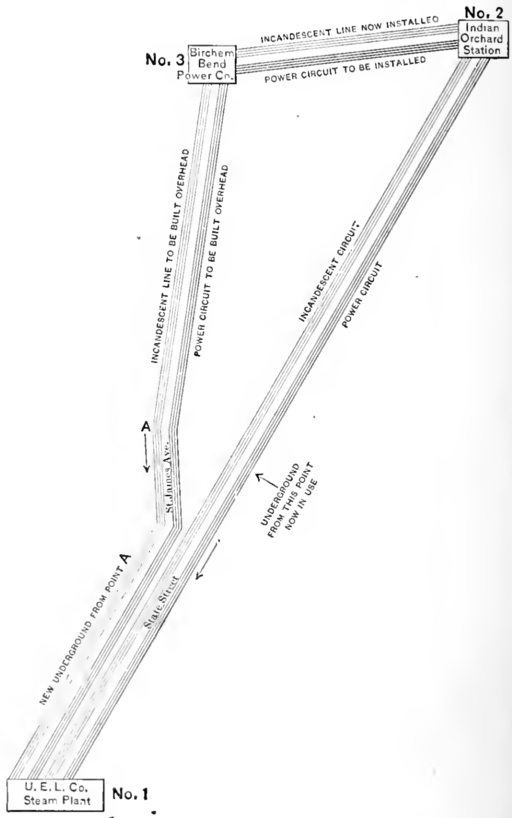

FIG. 4.—PLANT CONNECTING CIRCUITS, SPRINGFIELD, MASS.

is supplied with series incandescent street lamps, and with commercial lamps from circuits that start from the steam power electric station in that city. The steam power station on the water front in New Bedford supplies public and private service in Fairhaven by circuits that cross the river which separates the city and town. No step-up transformers are used, but all service in Fairhaven is taken either from constant, direct-current circuits or from 1,000-volt, single-phase lines that run back to the switchboard at the generating plant.

From the sub-station of the Springfield system, on the bank of the Connecticut River, distribution is carried out in that city and also in the adjoining towns of West Springfield and Longmeadow. For street and commercial lighting over this area constant-current arc circuits and two-phase circuits of 2,500 volts are utilized. The electric station in Pittsfield operates a constant-current circuit for incandescent street lamps in the town of Dalton. From the generating station in North Adams current is transmitted for public and private lighting in Adams, Williamstown and Clarksburg parts of which are eight to ten miles distant. For these transmissions the 2,200-volt, two-phase current at the main station is raised to 6,600 volts by transformers there, and the 6,600-volt current is lowered in pressure at sub-stations in Adams and Williamstown. From these two sub-stations the local distribution takes place. In the town of Blackstone, Mass., the sub-station receives electrical energy transmitted across the State line from a generating plant at Woonsocket, R. I.

Much the largest and longest transmission between a city gen-

FIG. 5.—400-KW UNIT, SPRINGFIELD, MASS., BIRCHEM BEND PLANT.

erating station and other cities or towns in Massachusetts is that which is just being put into operation by the Edison Electric Illuminating Company, of Boston. This transmission starts from the L Street station of the Edison Company on the water front in South Boston and extends to eighteen cities and towns, some of which are fully 25 miles distant.

This transmission has been made possible through the purchase by the Edison Company of the electric generating stations and systems in Woburn, Somerville, Watertown, Needham, Dedham, Milton, Dover, Canton, Natick and Framingham. The operation of these

FIG. 6.—BIRCHEM BEND CANAL AND TAIL-RACE, SPRINGFIELD, MASS., PLANT.

systems carries with it the supply of electrical energy in Woburn, Stoneham, Winchester, Somerville, Arlington, Dedham, Canton, Needham, Milton, Westwood, Wellesley, Natick, Framingham, Wayland, Ashland and Holliston. For the regulation and distribution of electric current in all of these places from the L Street generating plant, sub-stations are being equipped at Woburn, Somerville, Newton, Dedham, Milton and Natick. Between the L Street station and each sub-station a transmission circuit for 6,900-volt, 60-cycle, three-phase current has been erected. Parts of these circuits in Boston and some of the other cities through which they pass are composed of three-conductor, paper-insulated, lead-covered cables laid in tile conduits, but the greater parts of their lengths are made up of bare copper and aluminum conductors supported by wooden poles. The 6,900-volt current for transmission from the L Street station is obtained there at present by means of transformers that draw their energy from the 2,300-volt, 60-cycle, three-phase generators in the older part of that station. When the addition to this L Street plant now under way is completed, the 6,900-volt current for the transmission circuits will be developed in the armature windings of

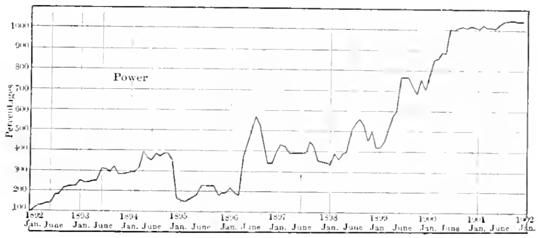

FIG. 7.—CURVE SHOWING INCREASE OF RECEIPTS, HARTFORD, CONN.

the 5,000-kw turbine generators that are being installed there. The circuits that now connect the L Street station with the most distant sub-stations of the system are thought to insure moderate transmission losses and good regulation, but when the loads at these distant sub-stations have increased, the transmission voltage at the generating plant may be raised to 13,500 by transformers.

At the various sub-stations connected to these 6,900-volt transmission circuits the line current goes either to static transformers or to motor-generators. The motors of these generating sets are three-phase, 60-cycle machines and receive the 6,900-volt current in their stationary armature windings. The generators of these sets deliver direct current. In the static transformers the three-phase current is reduced to 2,300 volts for general distribution, and for use in constant-current transformers and regulators. Such constant-current transformers and regulators supply all series circuits for both arc and incandescent lamps, and no constant-current dynamos are operated.

From the steam turbine generating station in Hartford, which also serves as a sub-station for the transmission lines that come in

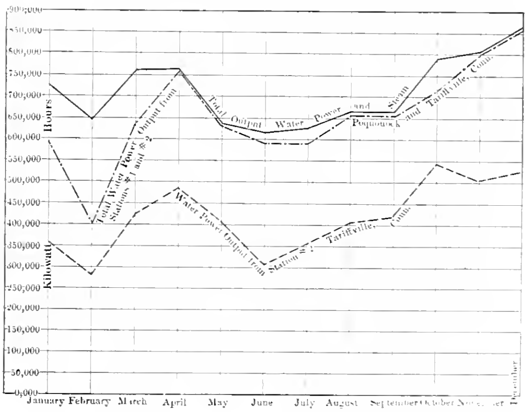

FIG. 8.—ENERGY OUTPUT CURVE, HARTFORD, CONN.

from the water power plants on the Farmington River, 2,400-volt, 60-cycle, two-phase current is sent out over feeder circuits that run to low-pressure distribution systems in adjoining towns. In this way the towns of East Hartford, West Hartford and Wethersfield are supplied at distances of five or more miles from the generating station.

At Providence there is another excellent illustration of an electric system that supplies numerous and distant surrounding towns from a large steam power station in the city.

From the generating station on the water front in Providence the ten outlying towns and cities that are supplied with electrical energy include East Providence, Barrington, Warren and Bristol on the east side and Johnston, Cranston, Warwick, Coventry, East Greenwich and North Kingston on the west side of Narragansett Bay. These cities and towns extend entirely across the State of Rhode Island, a distance of about 27 miles, and north and south along the shores of Narragansett Bay for as much as 22 miles. In the cities and towns that are nearer to Providence electrical energy is distributed at 2,200 volts, 60 cycles, single-phase, by circuits that ran directly from the generating station there. For the distribution of service in the more distant places two sub-stations have been established, one in Warren and the other in Warwick. Each of these sub-stations is distant approximately ten miles from the generating plant in Providence, and energy is transmitted to them at about 11,000 volts, 60 cycles, three-phase. In order to obtain this pressure for the transmission lines transformers are used at the main plant to raise the 2,200-volt current from the generators to 11,000 volts. The transmission line to each of these sub-stations consists of rubber-insulated, lead-covered cable laid in tile conduits for a distance of about two miles from the generating station. From the end of its underground cable the line to the Warwick sub-station is carried overhead on wooden poles. On the line to the Warren sub-station an armored cable 800 ft. long that passes under the Seekonk River connects the underground with the overhead portion of the circuit.

At each sub-station the 11,000-volt current is reduced in pressure to 2,200 volts by transformers for the distribution circuits. Constant-current transformers are also located at each sub-station for the operation of 6.6-amp. series circuits for arc lamps, and these transformers draw their energy from the 2,200-volt bus-bars there. The arc lamps operated by these transformers are all of the enclosed type.

As may be seen from the foregoing, there is a decided tendency toward the transfer of electric loads in small places to the steam power stations of large distant cities, because of the advantages of the development of electric energy on a great scale. In this way the transmission lines approach each other. Lowell, Lawrence, Haverhill and Newburyport, the Massachusetts cities along which the Merrimac River, already supply most of the electric lighting in towns that border its banks. With electrical supply from the Boston L Street station as far north as Woburn, and current from the Lowell plant as far south as Billerica, only one town, that of Burlington, intervenes between the circuits of these two steam power stations, which are about 24 miles apart. On the west Worcester is little more than 40 miles in a direct line from Boston, and the transmission lines from this latter city have already reached Ashland about 25 miles on the way. The time will probably be short before the circuits from one or the other of these large cities span the remaining 15 miles between them. In Canton the lines of the Boston Edison Company have traversed 15 of the 44 miles between that city and Providence, and there is no large generating station along the remainder of the distance.

In Bristol and North Kingston the lines from Providence are within ten miles of the steam turbine station at Newport, and it needs little gift of prophecy to see that the former rival capitals of Rhode Island are destined to furnish electric light for almost the entire State.

Another factor, the transmission of energy from water powers to a number of distant cities and towns in each case, is tending to bring scattered electric loads onto a comparatively few great systems. Perhaps the most striking example of this sort in New England is the forty-mile transmission from the isolated generating plant of 6,000-kw capacity on the Housatonic River, in Kent, Conn., to Cheshire, New Britain, Waterbury and intermediate places.

WATER POWER IN NEW ENGLAND ELECTRIC STATIONS.

During the first decade of electric lighting water power was little used in the stations of New England. In 1890 only six electric stations in Massachusetts, those at Holyoke, Leicester, Middleboro, Turner's Falls, North Attleboro and Lee were using water power, and the total capacity of all their wheels was only 685 hp. At Hartford, Conn., the first energy developed by water power was received from the Poquanock plant by a transmission of eleven miles, in 1891. It was about 1893 before the power of falls on the Winooski River several miles from the business center of Burlington, Vt., were utilized to operate the electric system in that city.

Manchester, N. H., is literally surrounded by water powers besides having a large fall near its center, but the first independent electric station built there, about 1886, was driven entirely by steam power.

FIG. 9.—EXTERIOR OF POWER HOUSE, CONCORD, N. H., WATER POWER PLANT.

The first electric lighting at Manchester was done with water power rented from the Amoskeag Manufacturing Company in 1882, but this power was abandoned when the plant was moved to the Brook Street station in 1886. It was not until 1890 that an electric station for the use of water power was built, and this station was located at Kelley's Falls, about three miles from the business section of the city on the Piscataquog River.

At Concord, N. H., on the Merrimac River, the steam-driven electric station was abandoned in 1892, and electrical supply there has since been drawn from the water power at Sewall's Falls, about four miles up stream from the business center of the city.

In Maine the great abundance of water power led to its early use in some of the electrical supply systems. At Lewiston and Auburn,

FIG. 10.—DAM AT SEWELL'S FALLS, N. H.

Me., cities that are separated only by the narrow Androscoggin River, and are a unit from a business standpoint, electric lighting seems to have been done with water power from the start, and four early water-driven stations are still in operation there pending the completion of a large modern plant about three miles up the river. Portland, the largest city of the State, depended on steam power for electric lighting up to 1898, though there are a number of undeveloped water falls within twenty miles of the business center, and one of the systems there still operates entirely with steam.

Several causes have combined to postpone the application of water power to the second decade of electrical supply. One of these causes is the idea, not yet entirely outgrown, that electric generating stations must be placed as close as possible to their loads. This idea had its only substantial foundation in the limitations of 110 and 220-volt

NEW ENGLAND CENTRAL STATION DEVELOPMENT.

direct-current service, and even here the necessity for a short radius of distribution applies to the sub-station rather than to the generating plant. With arc dynamos that ranged from 2,500 to 3,500 volts, and with alternating generators of 2,000 volts, a generating station might have been located five to ten miles from its connected load in order to utilize water power. Even with the moderate voltages just named available for such a short transmission, sub-stations might have been installed for service with direct current at 110, 220 or 500 volts near centers of distribution. But the transmission idea had not yet gained headway, and what many engineers knew as matter of theory, but few were ready to put into practice. Probably the strongest reason for the delay in the application of water power to electrical supply was the failure to fully appreciate its advantages. A saving in the cost of fuel was long regarded as the chief advantage of water power, and the large possible reduction in the labor of operation was in large measure overlooked.

FIG. 15.—GARVIN'S FALLS, N. H., POWER PLANT.

If water power was too much neglected in the first half of the period that covers the rise of electric lighting, the mistake is being rapidly corrected. In contrast with the four electric stations in Massachusetts that used water power in 1889, the number of systems operating with this power in 1903 was eighteen. While the combined capacity of all the water wheels in the electric stations of Massachusetts was only 545 hp in 1889, the year of 1903 found wheels of 10,334 hp so used among the electric water power system of Massachusetts as those of these of Springfield, Holyoke and Lawrence. In Maine more than a score of lighting systems utilize water power, including Augusta, Waterville and Bangor. New Hampshire, like Maine, depends largely on water power for electrical supply, and many of the smaller places as well as Concord and Manchester are lighted from this source. Besides Burlington, the largest city in the State, Montpelier, Bennington, Bellows Falls and numerous other places in Vermont are supplied with electrical energy from water power. Hartford afforded for some years the only prominent example of electrical supply from water power in Connecticut, but recently Waterbury, Cheshire and New Britain have begun to draw energy from an electric station on the Housatonic River.

The distances over which water power is electrically transmitted in New England are as a rule moderate. At Bangor, Me., the electrical supply comes from a station five miles up the Penobscot River at a point in the town of Veazie, where a dam is located. The great electric water power station on the Androscoggin that is being constructed for the supply of Lewiston and Auburn, Me., is only three miles up stream from the business center of these cities. To reach Portland, Me., the electric energy developed at Great Falls on the Presumpscat River is transmitted about fourteen miles. Of the four water-power plants that develop electric energy for Manchester, N. H., one is four miles, one six miles, one ten miles, and one fourteen miles from the sub-station in that city. Of the two water-power plants that generate electric current for the Springfield, Mass., system, the more distant is about six miles and the other about 5.5 miles from the sub-station near the business center.

Of the two water powers that supply energy to the electric system in Hartford, Conn., that at Poquonnoc is eleven miles, and that at Tariffville, thirteen miles from the city sub-station. Probably the longest transmission in New England, between a water power station and a city that it serves, is that extending from the electric plant near Bulls Ridge on the Housatonic River, in the town of Kent, Conn., to a sub-station in New Britain, a distance of about thirty-eight miles in an air line, and probably more than forty miles by the transmission circuit. This water power plant and rather long transmission system is owned by the New Milford Power Company, and the energy is to be used on the extensive system of the Connecticut Railway and Lighting Company, especially at Waterbury, New Britain and Cheshire.

FIG. 16.—GREAT FALLS, ME., WATER POWER PLANT.

As might be expected, the rather short electric transmissions of New England have not led to the use of extremely high voltages.

The line between Great Falls and Portland operates at about 10,000 volts, and the same is true of the transmission circuits entering Manchester and Hartford. Probably the highest transmission voltage in New England is that of 33,000 on the line above mentioned from Kent, Conn., to Waterbury, New Britain and Cheshire. The four transmission systems just named, and also most of the smaller ones throughout the same territory, operate with sixty-cycle, three-phase current. Where the line voltage is not more than 10,000 to 12,000, which is true for the great majority of transmissions, the more common practice is to develop this voltage in the generator windings and thus avoid the use of step-up transformers. This practice as to the equality of generator and line voltages exists in the Lewiston, Portland, Manchester and Springfield systems, but the contrary is true for Hartford and Kent. At both of the Farmington River plants that develop electric energy for Hartford the voltage of the main generators is 500 two-phase, and this is increased to 10,000 volts, three-phase by step-up transformers.

The generators just installed at the Bulls Bridge plant in Kent are rated at 1,150 volts each, and the transformers increase this pressure to 33,000 volts. Electric water power stations of New England are more notable for their numbers than for their individual capacities, but there are a few of these plants that compare favorably in size with the great majority of similar plants in other parts of the country. At the Great Falls plant whence energy is transmitted to Portland the capacity of each of the three-phase, 60-cycle generators is 500 kw, giving a total capacity of 2,000 kw for the plant. In the Springfield system the combined capacity of generators at the Indian Orchard plant is somewhat more than 2,000 kw, and the two 60-cycle, two-phase, 6,000-volt generators at Birchem Bend are rated at 400 kw each, so that these two water power stations have a generating capacity of fully 2,800 kw. At one of the Farmington River stations of the Hartford system, that at Poquonnoc, each of the two generators is rated at 600 kw, and the Tariffville system has two 750-kw generators, so that this system can draw 2,700 from water power, or very nearly the rated output of the two water-driven stations of the Springfield system. The Winooski plant that supplies light and power for the city of Burlington has a generator capacity of 1,080 kw, made up of three 2,300-volt, 60-cycle, three-phase alternators and six series arc dynamos. The Concord, N. H., system has a capacity of 1,000 kw in its generators at Sewall's Falls, this capacity being made up by five 2,600-volt, 60-cycle, three-phase alternators, and two arc dynamos.

An unusual feature of the Manchester system in the same state is the delivery of energy from four water powers to the same set of brushes at the sub-station in that city. At three of these water powers, Kelley's Falls, Gregg's Falls and Hooksett, the capacities, all in alternating generators, are 930 kw, 1,200 and 600 kw respectively. The fourth water-power station, that at Garvin's Falls, formerly contained only two generators each rated at 650 kw, sixty-cycle, three-phase, but a new dam and canal, together with a large extension of this plant have been in process of construction for the past year; this extension is designed to give the plant six generators of the type and capacity just named. These six generators will have a combined capacity of 3,900 kw, and this with the 2,730 kw of the other three plants will raise the rating of water-driven generators in the system to 6,630 kw. This capacity of water-power stations is greater than that possessed by any other electrical supply system in New England. Probably the largest generating capacity of any one station devoted to electrical supply is that of 6,000 kw in the new plant at Kent, Conn. This capacity is made up of six equal, three-phase, sixty-cycle generators, each of which is direct connected to a pair of horizontal turbine wheels. These generators operate at 1,150 volts, and six transformers are used to raise this pressure to 33,500 volts for the transmission line. Even the capacity just mentioned will be exceeded at the new water power plant above Lewiston and Auburn on the Androscoggin, which when completed will contain ten generators of 750 kw each. All of these generators will be three-phase, sixty-cycle, 10,000-volt machines, and each will be driven by a pair of direct-connected, horizontal turbine wheels. The generator capacity of this plant on the Androscoggin will thus just equal that of the celebrated station of 7,500 kw at Canon Ferry on the Missouri River, and will exceed the capacity of any of the famous water-power stations in California save that of 10,000 at Electra, and that of 11,250 kw rating at Colgate.

Unlike these notable California systems the electric water power stations of New England have to deal, as a rule, with rather low heads of water. At the Indian Orchard and Birchem Bend stations of the Springfield, Mass., system, the heads of water are 36 and 14 ft. respectively. At the Burlington, Vt., station the wheels work under a water pressure of 31 ft. Sewell's Falls, on the Merrimac River, afford a head of 15 ft. for the wheels that drive the generators of the Concord, N. H., system. Several miles down stream comes Garvin's Falls, with a head of 30 ft. that will be maintained by the massive stone dam now under construction, and still further down toward Manchester are the 16-ft. falls at Hooksett, both of which develop energy for distribution in that city. On the Piscataquog River, which joins the Merrimac at Manchester, are Kelly's Falls of 24 ft., and Gregg's Falls of 51 ft., both of which develop energy for the city last named.

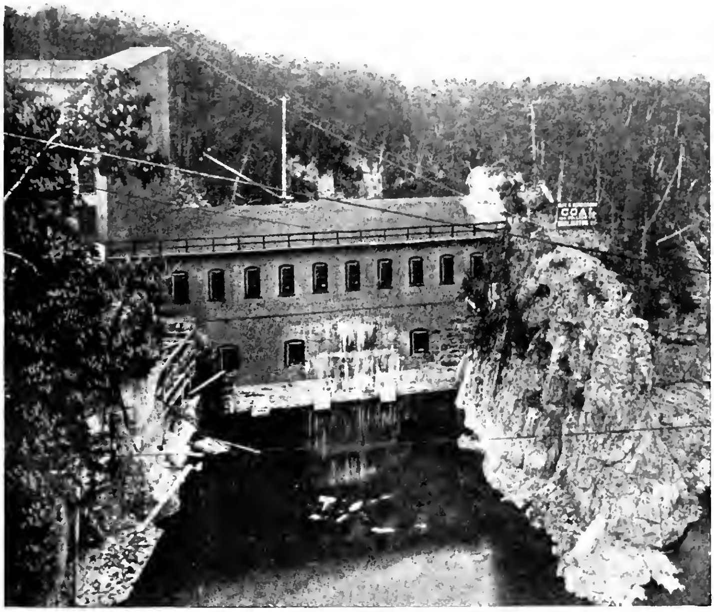

FIG. 17.—BURLINGTON, VT., WATER POWER PLANT.

To develop 10,000 horse power in the new station above Lewiston, Me., a fall of 32 ft. in the Androscoggin will be maintained by the new concrete dam. At Great Falls the generators that develop electric current for distribution in Portland are driven by wheels that work under a head of 37 ft. The stations on the Farmington River that develop energy for distribution in Hartford operate with water heads of 23 and 32 ft. respectively, the earlier plant having the greater, and the later, or Tariffville, plant the lesser head of water. At the 6,000-kw station in Kent, Conn., the largest now driven by water power in New England, the greatest head of water, that of 115 ft., is also found. It is worth noting that the greatest station capacity, the largest head of water, the highest voltage, and the longest transmission in the entire territory under consideration are to be found in the system of which the plant just named forms a part.

All of the water power stations above mentioned, and most if not all of the smaller ones in the same states, are equipped with turbine wheels. In all of the recent plants the turbines are of the horizontal type, and are direct connected to the generators. At some of the older and smaller stations the turbine wheels, though horizontal, are belted to one or more shafts that in turn drive the generators, through belt connections, as is done in the Burlington plant. In other cases, as at the station of the Concord system, each pair or set of horizontal turbines is belted to a single generator. The old type of connection in which vertical turbines are geared to a horizontal shaft, and this shaft is belted to the generators, is being generally abandoned though still in use at a few of the older and smaller stations. Storage of water for use at electric stations has not received the attention that it deserves, but some of the plants are well situated in this respect.

Above the Burlington plant on the Winooski the dam forms a pond three miles long, and during more than ten years of operation the use of steam has been necessary on only two days because of lack of water. The new stone dam at Garvin's Falls on the Merrimac River sets back the water to a distance of several miles up stream. In the great upland bogs of Brookfield the water is held as in a sponge, and the Chicopee River which rises there has a remarkably constant and even flow, so that the stations at Indian Orchard and Birchem Bend generate more than 90 per cent. of the entire output of electrical energy in the Springfield system. Although the Farmington River has a rapid descent, and the facilities for the storage of its water are far from what could be desired, only 1,009,598 kw hours out a total of 8,577,699 kw hours distributed by the Hartford system during the calendar year of 1901 was derived from steam power. In other words, water power furnished 88.2 per cent. of the energy output of the system in that year.

In Concord, N. H., the average week-day output of the electric system was about 6,800 kw hours during the year ending June 30, 1901, and the total rated capacity of all lamps and motors connected to the system was 1,850 kilowatts approximately. In this same year only about 500 tons of coal were consumed in the operation of the Concord system, and the water power at Sewall's Falls did the remainder of the work. Few, if any, water powers in New England are more constant than those along the Presumpscot River, which forms the only outlet of Sebago Lake. This lake has an area of fifty square miles, and a drainage of 470 square miles, so that each square mile of the lake area receives drainage from less than ten square miles of territory, on an average. A result is that records extending over more than ten years show a maximum variation of only 5.75 feet in the lake levels. A dam at the outlet of this lake regulates the height and flow of water, and gives it exceptional value as a reservoir. Besides the storage between wet and dry seasons afforded by this lake, the station at Great Falls has a pond behind its dam that is about one mile long, 1,000 feet wide, and 15 ft. deep, the Portland electrical supply system. During the year 1903 not a pound of coal was burned by the Portland system.

The electric systems centering at Lewiston, Portland, Burlington, Concord, Manchester, Lawrence, Holyoke, Springfield, Hartford and Waterbury will have generators of 31,674 kw total capacity connected to water-wheels in their stations, when the plants now under construction at Lewiston and Garvin's Falls are completed. As there are eighteen electric stations using water power in Massachusetts, and more than twenty such stations in Maine, the total capacity of generators driven by water power in the electrical supply systems of New England is probably between 40,000 and 50,000 kw.

With all this, the development and transmission of water powers is still in its early stages, and another twenty years of electric lighting will see the greater amount of energy used in supply systems drawn from the rivers of New England.

Electrical Standardizing Bureau for Canada.

A deputation of Canadian electrical interests has waited upon the Minister of Inland Revenue asking that the government establish an electrical standardizing bureau, to be maintained independent of any other branch of the public service, and placed in charge of a qualified electrical expert, at whose disposal should be placed trained assistants and proper facilities. The delegation also asked that the law be amended so that if any device was found in the possession of any one to prevent the proper registration of electric current, it should be prima facie evidence for his prosecution and conviction.

Report of St. Louis Railway Test Commission.

A full meeting of the executive committee, appointed to determine the nature and scope of the electric railway tests to be made at St. Louis and elsewhere during the coming summer, was held at St. Louis on Friday and Saturday, May 6 and 7. The committee consists of Prof. W. E. Goldsborough, chief of the Department of Electricity, Universal Exposition, chairman; Prof. H. H. Norris, Cornell University, superintendent of electric railway tests, and Profs. B. V. Swenson, University of Wisconsin, and H. T. Plumb, Purdue University, assistant superintendents of electric railway tests. After careful study of the reports of the engineering committees of the suggestions of the advisory committee, and of the excellent facilities afforded by the Exposition officials, the executive committee decided to undertake the following series of tests:

(*a*) Tests on the service capacities of electric railway motors. Equipments will be operated upon the special tracks at different rates and durations of acceleration, coasting and braking, with different lengths of stops, in order to determine the heating of the motors under conditions approaching as nearly as possible those of commercial practice. The motors will also be tested separately for heating and for the determination of their torque curves and accelerating power. This will render possible the comparison of the performance of the same equipment upon the track and test stand.

(*b*) Acceleration tests. Acceleration tests upon single cars and upon multiple equipped trains will be made to determine the ability of the equipment to bring the cars to speed quickly and economically.

(*c*) Braking tests. Braking tests upon single cars and multiple equipped trains will be conducted in order to determine the quickness of action, the shapes of the braking curves, the relation between the braking forces and the applied pressures and the best methods of application of the braking forces.

(*d*) Tests upon train resistance. Determinations of the resistances due to the rails, to the journals and gearing and to the air will be made by systematic and complete series of runs. The effect of the shape of the car body will be carefully investigated. The methods to be used in measuring train resistance comprise the use of calibrated motors as the sources of power, the hauling of the car under test by calibrated dynamometers, and by noting the falling off in speed while the cars are coasting. The pressure of the air upon different parts of the car will be recorded by means of self-registering pressure gauges. In addition to this definite series, a number of other tests will be conducted upon various exhibits in the Palace of Electricity in order to determine their efficiency and reliability.

Sections (*a*), (*b*) and (*c*) of the tests will be carried on upon the tracks which have been built for the purpose by the Exposition. These are of substantial construction, conveniently located, and of a total length of about 4,500 ft. For the tests described under section (*d*) the Indiana Union Traction Company has provided a stretch of eight miles of straight and heavily ballasted track. The resistance tests will be made after the completion of the programme.

In all of the above work, graphical records of the measurements will be obtained by the use of autographic instruments which will be either built for the purpose or supplied through the co-operation of the manufacturing and operating companies and the technical colleges. The National Bureau of Standards will materially aid in this work by providing facilities for the calibration of all of the instruments. For the purpose of comparison, the various railway equipments will be divided into several classes, including car weights up to forty-five tons, as follows: (*a*) Light city service equipments, (*b*) heavy city service equipments, (*c*) light interurban service equipments, (*d*) heavy interurban service equipments.

The actual work of observation and calculation will be carried on under the personal supervision of the superintendents by a corps of young men carefully selected from among the graduates of leading technical schools, the total number of observers being between thirty and forty. The Exposition management is co-operating enthusiastically with the railway test commission in providing ample facilities for the tests and substantial results of permanent value to the profession are confidently expected.

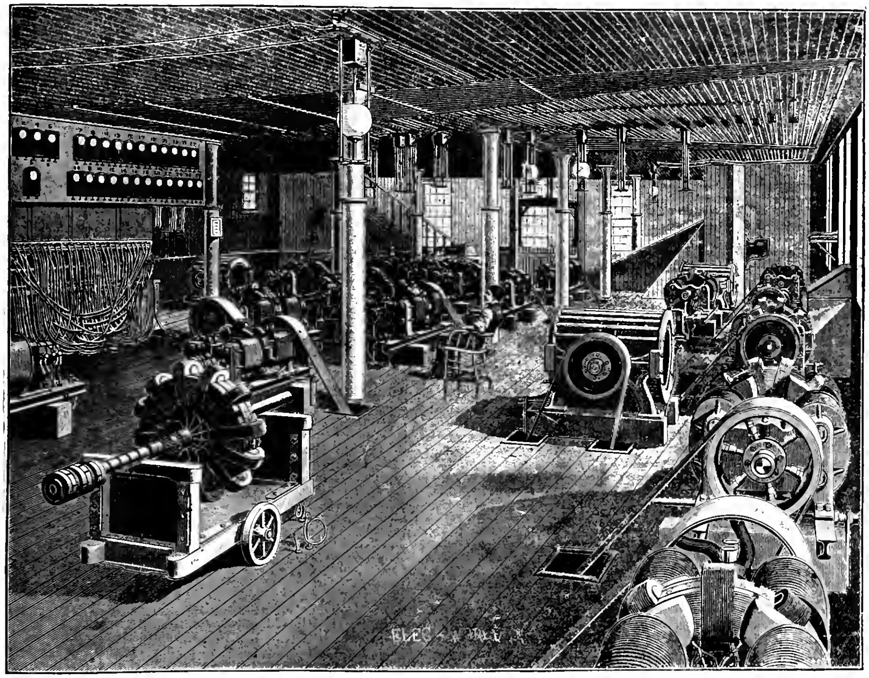
At the present time a large part of the equipment is already at St. Louis, the organization is complete, and the ranks of the testing corps have been filled with earnest young men.

The Boston Electric Light Convention of 1887.

IT is seventeen years since the National Electric Light Association visited the city of Boston, although the electrical development there has been such as to justify a more frequent return. So much electrical history has been written since 1887 it has occurred to us that many readers of the Electrical World and Engineer would like to refresh their memories in regard to what was done by the Association on the occasion of its previous visit; while those who have entered the field of electric light and power since that time will also be put more closely in touch with its evolution and development, by the present brief retrospective sketch. Neither the art nor the Association was very old at the time referred to, and to all except those gifted with prophetic minds the present close harmony and alliance between the arc lighting and incandescent lighting branches of the industry then seemed impossible. In fact the tendencies which have made electric lighting one art instead of two were already at work, but were not fully recognized. Aside from the inevitable trend of financial and commercial interests towards consolidation there were two agents beginning to make themselves felt, to which alone might be attributed almost entirely the present status of the art and the industry, namely the adoption of the alternating current and the introduction of the direct-current motor. It is sharply within the memory of veterans who attended the Boston convention seventeen years ago that the impressive feature of that affair was the large exhibit made of direct-current motors, although singularly enough these were designed for arc lighting circuits, to be operated in series, rather than for the incandescent circuits to be operated in parallel, as virtually all motors are to-day. The same year, 1887, was a landmark also as being the time when Tesla came to the front and changed the whole aspect of things with his polyphase inventions and motors.

In connection with the visit to Boston the Electrical World and Engineer of that day presented to its readers an elaborate wood cut engraving which we are emboldened here to reproduce for its historical interest, showing the interior of the Ferdinand Street station of the Boston Electric Light Company—one of the four stations then under the management of the late F. A. Gilbert. The dynamo room here shown—one of three floors—contained 16 Brush arc dynamos of 65-light capacity, and 7 of 30-light capacity, two Thomson-Houston arc machines of 30 lights, and one of 50-light capacity. This gave the station a total capacity of 1,360 lights, all of which were in use. With regard to electric lighting in general in Boston at the time of the last convention, it is rather difficult to give the exact figures, but the arc lighting system at that time had apparently a station capacity of about 3,000 arcs and in 1888-9 had 2,171 in service. At the end of 1887, the Boston Edison Company had connected on its three-wire system an equivalent of 8,380 incandescent lamps of 16 cp and about 80 motors of an aggregate of 300 hp. All these various services being now consolidated under the management of Mr. C. L. Edgar, the growth since that time can be summarized by stating that the Boston Edison Company at the beginning of May, 1904, was operating 642,406 incandescent lamps, 9,546 arcs and 23,891 hp of motors. Our readers can see for themselves at a glance how manifold has been the increase.

The convention of 1887 was called together by President J. Frank Morrison, at the Parker House on August 9, and the list of those in attendance revives memories of men who did valuable work in the development of the industry, and have passed away. Mr. Morrison, in his address, called attention to the development of the alternating-current system, then in its infancy, but, strangely, his remarks did not include anything about electric motors—possibly for the disinterested reason that he was devoting a great deal of his remarkable personal energy to their introduction. An interesting report was made by the legal committee on the "Status of the Patent System," signed by Messrs. J. F. Morrison, Frank Ridlon, Walter C. Kerr, Frank J. Sprague and A. Steuart. This is a rather striking group of names, and it is pretty safe to say that the gentlemen have never been associated technically since. Dr. A. V. Garratt then presented an extremely interesting and valuable report on "Wire Gauge," which he accompanied by an elaborate table, the calculations in which were made by himself and Messrs. H. H. Eustis and P. Keilholtz. A further interesting report on the subject of wire was that of the Committee on Insulation, consisting of Prof. E. J. Houston, W. D. Marks, Carl Hering and M. M. Garver. The report was an admirable document and most of its ideas and recommendations have now become part of the art; in fact, the National Code may be said to have here had its beginnings.



Brush Lighting Plant, Ferdinand Street, Boston, 1887. *(From a Wood Cut in The Electrical World.)*

The subject of alternating current came up again in the report or paper read by Mr. M. M. Slattery, so well remembered from his connection with the subject in the early days of the Fort Wayne Company. The wonderful development of the system since that time has justified the advanced stand then taken by this lamented pioneer—with perhaps one point of difference, that whereas he urged that the adoption of the alternating system with its smaller wires would release the companies from the attacks then waging on overhead wires, it may be said that modern central station polyphase work has been one of the greatest compelling causes for undergrounding the circuits.

Mr. E. R. Weeks, of Kansas City, now a past president of the Association, presented a thoughtful paper on "Electrical Education," and here again one finds the keynote of progress struck. Aside from the better education of engineers and employees and the establishment of mutual improvement societies amongst the men, Mr. Weeks advocated examinations by municipalities as to the competence of men engaged in electrical occupations, since the safety of life and property in growing degree depended upon their faithful and intelligent work.

Lieut. J. B. Murdock, at the beginning of the second day—when the convention was called to order by Mr. Ralph W. Pope—read a valuable paper on "Electric Lighting for the New Cruisers." We are now familiar with the idea of the new navy, but at that time it was not a "fleet in being," nor were marine lighting methods very well developed; and this paper summarized all that had been done and most of what was known up to that time. There is perhaps no particular reason why the Association to-day should not still consider such subjects, but it is the fact that of late years it has pretty well discontinued all discussion of work connected with isolated plants, except so far as such plants come in competition with central stations. To this extent the Association has narrowed its functions, so that papers read on the subject of isolated plants are to be expected before bodies like the American Institute of Electrical Engineers, or the New York Electrical Society. The Association can well assert that the greater magnitude of the industry to-day gives it subjects enough for treatment without going beyond the central station borders. It may be noted in this connection that at the meeting a large part of the time, as usual, was taken up with a discussion on the new constitution. In those days the constitution was a burning question, because one or two pretty palpable efforts were made, by men with more daring than judgment, to capture the machinery of the Association in order to promote certain objects which were hardly calculated to enhance the usefulness of the organization; and for some few years the proceedings of the body were considerably enlivened by this kind of politics. Fortunately, for some time past the Association has been able to give its attention strictly to the treatment of the technical and commercial questions in which it is broadly interested.

One of the most important features of the proceedings was that dealing with storage batteries. Mr. C. O. Mailloux read a masterly paper on the "Status of the Battery," and justified, as he has always done, his strenuous advocacy of that useful implement. And while it has not realized all the hopes of its friends in connection with traction work, it has certainly proved of immense value in connection with electric lighting. Though some of those present may have thought that Mr. Mailloux overstrained his statement of the case in this respect, subsequent events are all that Mr. Mailloux needs to point to for vindication. A melancholy interest attends the other paper on storage batteries, which was submitted by the late Mr. Anthony Reckenzaun, and which dealt specifically with batteries for electric locomotion. This brilliant young engineer, whose loss was so keenly felt on both sides of the Atlantic, made a modest presentation of a great deal of his own work, creating a highly favorable impression. But it is melancholy to reflect that, although we have now hundreds of electric automobiles in operation, there is probably not a single storage battery car turning its wheels today in the United States. In connection with this paper, the subject of electric motors came up and was interestingly discussed, but incidentally let us note that the subject of the stationary power motor was passed over almost without a word of reference, apparently because the versatile Mr. Sam Duncan, of Pittsburg, thought it better to turn in the documents in regard to that item to the Executive Committee. This, however, was redressed largely by the splendid exhibit of Baxter motors made at the hotel.

The last item on the programme was a discussion of "Underground Wires," in regard to which there was a sharp little discussion, and then Mr. Duncan touched on a delicate matter in calling attention to "pools" which had been formed on arc light carbons. This gentleman remarked that if the arc light men had got to break down such a pool every two months they ought to be in shape to do it. The result was that a committee of three was appointed to deal with the matter. We should hardly like the job of compiling a list of all the pools which have been formed in the electric lighting field since that time, some of which have succeeded, and others of which were badly "busted." A few could be mentioned which are understood to have a lively and healthy existence at the present time.

Part of the convention was a very fine exhibit of electrical apparatus, including several scores of exhibitors. This feature of the convention is still maintained, although hardly with the vigor and magnitude of earlier years, since apparatus is now standardized, and people are tolerably familiar with it. The great feature of the outside exercises, however, was the trip given to about 250 of those present by the old Thomson-Houston Company. The excursion included a trip on a steamer, a visit to the Thomson-Houston works at Lynn—where were found Prof. Thomson and E. W. Rice, Jr., and A. L. Rohrer—and a banquet at the Point of Pines. The factories, at that time as now, under the direction of Mr. C. A. Coffin, embraced about 80,000 sq. ft. of floor space, and the main item in connection with them was that they turned out 300 arc lamps weekly. Mr. Coffin's report for the General Electric Company this year, 1903-4, shows a floor space for the General Electric Company of 3,700,000 sq. ft., and 17,000 employees. The Lynn works alone during the past year have had an increase to their buildings of over 300,000 sq. ft. The banquet down by the seashore that night was a remarkably interesting affair, and was signalized by the fact that Mr. Coffin so far forgot his wonted reticence as to make quite a long speech, which was couched in felicitous terms, included two or three good stories and evoked thunders of applause. The response and recognition in behalf of the Association to this hospitality and to Mr. Coffin personally were not only due and appropriate; but, in view of the intimate intertwining of the relationships between the great manufacturing company and the electric lighting art, which has continued from that day to this, the record does one good to read and recall these seventeen years later. In fact, this brief review which touches only the salient points of a busy week, may serve to bring up in the minds of our readers some reminiscences of other events worthy to be gone over again by the survivors of a memorable convention.

"Let the Trolley Lights be Burning."

In the future we may hear of trolley cars as lifeboats. An ingenious use of a car and its arc headlight was recently made at Redondo, Cal., on the Pacific Coast. A lumber schooner anchored off the beach broke her chains at night and was blown on to the lee shore. Efforts were immediately made to rescue the men, and one of the interurban cars of the Los Angeles & Redondo Railway Company was run to a point whence the beams of its headlight could be thrown on the vessel. In this manner assurance of help was given to the crew of the boat and the light aided the rescuers in getting a life line to them. Probably we shall now hear of English bathing machines available as trolley cars by day along the beach and as lighthouses by night. These machines anyhow could be hauled up and down by motors, and could light up the esplanade at night.

Radium "Mother Ore."

The *Neue Wiener Tageblatt*, Vienna, reports that at a meeting of the Mineralogical Society Dr. F. J. Becke spoke of uranium pitchblende ore, the mother ore of radium. Prof. Becke, jointly with Prof. Suess, has made very searching investigations at Joachimsthal, the place where uranium is mined. It occurs mainly in mica slate, in the deep workings of the former levels of the silver mines of Joachimsthal. He mentioned the experiments which were made with uranium pitchblende ores at the Imperial Museum of Natural History. These ores have been in possession of the museum since 1806. The experiments demonstrated that, in spite of their age, they have lost absolutely nothing of their intensity of radioactivity and of the energy of their electric properties. They do not differ in any way from the ores now taken at Joachimsthal.

A Resumé of Incandescent Electric Lamp Exhausting.

By S. E. Doane.

The exhausting of incandescent electric lamps has developed into a highly specialized branch of the lamp manufacture. In order to crowd a description of the development of this portion of the art into the limits of one article, it will be necessary to abbreviate portions of this description considerably. The history of the art up to the development and adoption of the present chemical exhausting method will be passed over rapidly. The latter method will be considered as thoroughly as the allotted space will permit.

The first incandescent lamp of the modern type ever constructed was exhausted on a mercury pump. Mercury pumps were used for lamp exhausting for nearly twenty years before they were superceded by the present chemical process. These mercury pumps were of two general types. Each type had its advantages and disadvantages, but overshadowing all was the need for better brains than could be obtained for the attendance demanded by all mercury pumps.

Either type of pump required active, intelligent men of strong physique. Men with these three qualities were fitted for far more pleasant duties, so that the supply of such men was always far short of the demand. The result was that the pump rooms always contained many men who, while possessing some of these qualities, were not completely qualified for the exacting service. Many of those who were qualified, and who, for brief seasons, filled the hearts of the lamp manufacturers with joy and hope for the future, would be found after the first pay day to be confirmed drunkards. Drinking men seemed more numerous in the pump rooms than elsewhere. I can see, as I look back, that this was because we tolerated more of it in the pump rooms than elsewhere. We were thus obliged to put up with insufficient mental capacity on the part of strong, faithful workmen, accepting the widened voltage range, shortened life and decreased candle-hour performance of the lamps improperly exhausted, year after year, gradually improving our condition as we developed the processes. The changes and improvements did not essentially modify the general practice, which was as follows:

The mercury pumps used by all lamp manufacturers in this country, which commenced operation not later than about 1885, were of the Sprengel type. Many of the companies began about this date to change to the Geissler form of pumps. Companies starting at a later date without exception so far as the writer can learn, used the Geissler form. The reasons for this will appear as we discuss the faults of the Sprengel pumps.

The Sprengel pump consisted essentially of a stream of mercury falling through a glass tube. All systems of this class had the following good qualities and faults:

The pumps gave a good vacuum, were cheap, simple to construct and to repair. When a pump failed only one lamp was injured. Every lamp was individually exhausted, which insured its being exhausted at just the proper voltage, when conditions were uniform, providing the operator was competent. We were content to have a pump which would procure for us a good vacuum, when the business was young. It was some time before we awoke to the fact that there were other requirements.

As we discovered the various new requirements, we also discovered fundamental faults with our apparatus and methods. These faults were finally found to be so serious that so far as I can learn every company in the country but one abandoned the Sprengel form of pumps for the Geissler form before ultimately adopting the chemical exhausting process.

At least every third man in the pump room (the men worked in teams of three in the best developed system) had to be an expert. The men were much exposed to the poisonous fumes of the mercury. Their hands were almost always black with an amalgam of mercury and grease. Many men were incapacitated because of mercury poisoning, and as this became known it became more difficult to secure the requisite grade of intelligence.

The men were required to be on their feet all day, working almost constantly with their hands on a level with their shoulders, a blazing row of lamps in front of them and sometimes behind them. While every effort was made in summer to keep the pump rooms cool, air drafts were tabooed and there was no way of escaping the light and radiant heat from the lamps. Add to this the danger to health and it will be seen how difficult it was to obtain the kind of men required.

Pumps did not all work at the same speed. The glass tubes from which the pumps were made were of different diameters, which was one reason for the differing speeds. The cleanliness as well as the diameter of the principal glass tube of the pump affected its speed. The diameter of the hole in the glass tube attached to the lamp through which the air was exhausted also affected the speed. The differing speeds was a matter of much importance for the following reasons:

The completed lamp must not only be free from gases and vapors, but must also have had those parts capable of giving off gases and vapors, thoroughly freed from them. The only way we knew to accomplish this was to highly heat everything we wished to free from gas. We had three things to heat: the glass, the filaments and the joints between filaments and leading-in wires.

The glass was heated by an asbestos cone-shaped hood painted black on the inside. The heat from the lighted lamp furnished all the heat necessary. The lamps could be heated hot enough to cause the bulb to collapse if the hoods were made too thick. The filaments were also heated sufficiently by the current, but the joints were not heated sufficiently unless the current was passed through the lamps at a time when the gases were of just the right pressure to allow current to pass across the vacuous space from joint to joint. The current would not pass across this space, if the gas pressure was either too low or too high, and we had very little latitude in this respect. If we put sufficient voltage on the lamps to pass this current from joint to joint before the gas pressure in the lamps was sufficiently high, we burned the surface of the filaments. Filaments thus burned varied in color from light bronze to sooty black. If we waited too long and the gas pressure had been a little too much reduced, we could only pass this current from joint to joint by putting a destructively high voltage on the lamp, and if it had been too much reduced we could not heat the joints at all.

We found difficulty in making uniform filaments, which difficulty we still have, in a much reduced degree. This non-uniformity made it necessary for us to burn each lamp on these pumps at a different voltage, as at the same voltage a lower voltage lamp would get hotter than a higher voltage lamp and a hotter lamp would exhaust more quickly than one relatively cooler. Thus it will be seen, lamps were exhausted at various speeds for the reasons that (1) the pumps themselves were of different speeds; (2) the tubes through which we exhausted the lamps were contracted to slightly different diameters, and (3) the lamps were only exhausted at the same temperatures when the judgment of the operator was good.

The Geissler pump enabled us to get around these difficulties, but also introduced some of its own. The advantages were as follows:

1. The pumps were all of the same speed. 2. While the lamps were not exhausted through tubes any more uniform, the "slow" lamps being connected to the same reservoir as the "fast" lamps they balanced up fairly well, as we had twenty or more lamps on one reservoir. 3. We could not exhaust the lamps at so nearly the same filament temperature, but the conditions under which we exhausted made all the lamps of the same temperature of glass, and consequently of the same temperature and pressure of gas. This was because all the lamps on one Geissler pump were heated in one hood. This hood was raised to a high temperature by gas flames. We did not depend upon the filaments to produce the initial temperature which very much reduced the liability to burn the filaments.

In addition to these three important advantages we could keep all hoods at the same temperature, start all pumps simultaneously, give all pumps the same number of strokes, flash all lamps simultaneously, thoroughly protect the mercury from contact with the air, and we required only one high-grade man in the pump room, where formerly one-third of the operators had to be high-grade men.

We now felt that a great stride had been made in the exhaustion of incandescent lamps, but additional experience with the Geissler pump brought to light faults which still left much to be hoped for. The faults were as follows:

1. They were more expensive to operate, for the following reasons: (*a*) If one lamp leaked, the whole lot of lamps on this pump could not be exhausted. If the leak was only a small one, we would damage all the lamps on the pump. (*b*) The pumps were fragile, and if a lamp was accidentally broken, or if in any other way air was admitted accidentally, the pump was liable to be ruined. Lamps had to be more carefully inspected for leaks and glass work had to be more carefully done.

2. We still were unable to make lamps of exactly the same voltage. The lamps on one pump would necessarily have to be handled as a unit, which would mean that lamps designed for the same voltage would all have to be exhausted at the same voltage.

It became increasingly apparent as the effort was made to improve quality and reduce cost, that it would be strongly advisable if some means be found for individually exhausting lamps which did not possess the prohibitive faults of the Sprengel pump system. Some of the companies went so far as to construct some very small Geissler pumps to take one lamp each. It is hard to say what the outcome of this would have been, had not the chemical process been developed about this time.

The mechanical pump systems came into use about this time. All of them were open to the objections which held with the Geissler. Pump makers did not seem to appreciate the fact that whether a pump used mercury or not, it was simply and solely a pump. Some very good mechanical pumps were made, but most of them had a capacity greater than that of any Geissler pump. In order to get a reasonable output for the money invested, it was necessary to exhaust an even larger number of lamps simultaneously. This offered no escape from the troubles of the Geissler pump systems, and hence came into only limited use.

The chemical process was brought to us by a lamp maker. He knew the drawbacks of the mercury systems. This process possessed the advantages of the Sprengel system, the advantages of the Geissler pump system, and also some advantages of its own, without the conspicuous disadvantages of any of the previous systems.

While the Sprengel pump system only required that every third operator should be an expert, the chemical system required that every operator should be an expert, but it made it possible for us to secure experts, by entirely removing the disadvantages which made it so difficult for us to get a good class of operators. We found we had no difficulty nor do we now have any difficulty in securing plenty of young women of good intelligence who find the chemical exhausting work rather pleasant than otherwise. Every operator sits down to her work, has only one lamp on the pump at a time and is able to exhaust every lamp according to its individual requirements.

Two articles of any kind differ in some slight degree. This is true of incandescent lamps with special reference to the manner in which they exhaust. It may be that in one the joints between the filament and the platinum wires are larger or the joints are a little closer to the glass stem, or that the lamp has not been heated quite so hot in the preliminary heater or perhaps the bulb is of slightly different internal dimensions. Be the causes what they may, the differences are sufficiently marked to be quite apparent to the operators. This was all fully realized during the closing days of the mercury pump systems, but the vital difference this made to the candle-hour performance of the lamps has never been so fully appreciated as since we began to use the chemical process of exhausting. The chemical process of exhausting consists roughly of mechanically exhausting a heated lamp to a pressure represented by a column of mercury about .125 mm. high. This is equivalent to about 1/6000 of an atmosphere. The lamp is sealed off from the pump and phosphorous is vaporized and passes into the lamp bulb while the filament is very hot and while an electric current is passing through the gaseous contents of the bulb. The vapors of this metal enter into an electrochemical combination with the gases, forming solid precipitates, if the conditions are proper.

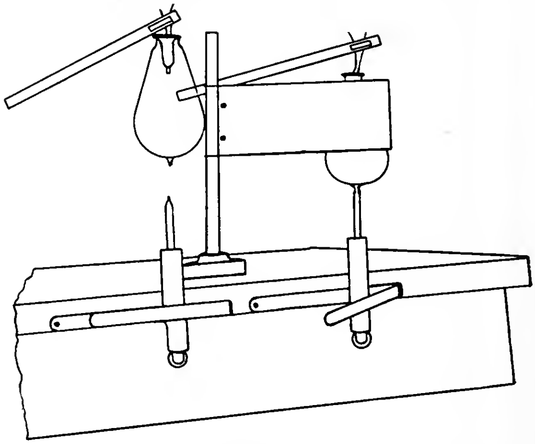
This whole operation from the time the lamp is first lighted up on the pump to the time it is completely exhausted requires approximately sixty seconds. During this time the following changes take place in the lamp bulb:

About one-half minute after the lamp is first placed upon the pump and before the lamp is shut off from the pump, current is passed through the filament. Current also passes from joint to joint across the vacuous space, heating both joints white hot. The joints are held at this temperature for a few seconds after which the current is reduced and the pump is given a few seconds to remove the gases which are dislodged by this heating. This takes about five seconds under usual conditions. The tube connecting the lamp to the pump is then closed very close to the lamp. The current is again increased until it again passes through the vacuous space from joint to joint. The first effect of this current flow is to again raise the temperature of the joints to a white heat. After about a second, without changing the voltage around the lamp, the blue flame which was playing between the joints, gradually expands, the color gradually changing from the first dark blue shade to a beautiful light blue, the joints meanwhile cooling somewhat. As soon as the lamp reaches this condition, the phosphorous which has previously been painted on the inside of the glass tube leading from the lamp is vaporized and the vapors passing into the lamp bulb react with the gases in the bulb, causing the blue to disappear. The effect of the sudden disappearance of the blue color is to make the lamp look very yellow. It is a common expression in the lamp factories to say relative to this portion of the exhausting process, that the lamp "turns yellow."

In order that the current may pass from joint to joint across the vacuous space the pump must necessarily produce a higher vacuum than is usual with mechanical pumps. The pump used in this work is of the ingenious variety which depends upon an oil-covered piston to displace all the air in the pump cylinder. The pump is so constructed that a little oil is always passing into the cylinder and is forced up through the exhaust valve with the gases which are being expelled. This oil is used over and over again. It is free from occluded gases, contains no volatile oils, and has a low surface tension. Care is taken to select an oil with these characteristics.

A mechanical pump of this description never produces a vacuum so high that there is any difficulty in passing current from joint to joint in the lamp being exhausted upon it. Care has to be taken with these pumps to be certain that they are always in such condition that they will produce a sufficient vacuum.

The present exhausting system has its faults. Any exhausting system will have faults, until a system is devised which automatically



CHEMICAL EXHAUSTION OF LAMPS.

keeps itself in repair and also automatically and perfectly exhausts lamps without the interposition of human judgment. The faults which concern us the most are as follows:

1. We must still have expert operators. 2. We still depend upon a system of pipes and valves which will occasionally develop leaks. 3. Pumps occasionally get out of order. 4. The chemical reactions which produce the vacuum are sensitive and atmospheric and chemical conditions occasionally give us new problems.

A better understanding of how this chemical exhausting is performed will be gained from the following description referring to the accompanying sketch. The operators are all seated in front of a long bench behind which are a number of little pumps. These pumps occupy about four feet of floor space and stand less than three feet high. They run continuously, being piped by the shortest possible connections to the face of the bench. Each operator utilizes one cylinder each of one of these pumps.

In the sketch the lamp on the left is exhausted and ready to be removed from its clip. The lamp on the right is shown thrust into a bit of rubber tubing. This tubing passes through a pinch cock on the edge of the bench.

In front of the lamp is a piece of metal that shields the eyes of the operator when the lamp is brightly lighted. The piece of metal can be swung around so that it can shield the operator from the light from either lamp.

While the lamp on the right is being exhausted, the lamp on the left is being removed from the clip which suspends it by the leading-in wires, another lamp is then thrust into the rubber tubing and connected to the clip. By this time the lamp on the right is sufficiently exhausted and current is passed through it by means of a rheostat on the left of the operator, and the process of exhausting is completed as indicated earlier in this article. After the exhausting is completed the tube through which the air is exhausted is sealed off by the blow pipe flame which much resembles the jeweler's blow pipe flame, familiar to every student.

Bits of glass, dust, moisture from the air, phosphorous, etc., collect in the pipes and interfere at times with the action of the pinch cock valve. It is necessary to watch very closely to see that the lamps are being exhausted under the desired conditions.

Each type of lamp behaves a little differently from another type.

The tubular lamp is difficult to exhaust because the phosphorous gases are heavy, the residual gases in the lamp are light; the phosphorous is in the form of gas at a high temperature only, and the lamps cool quickly from the high temperature of the heater in which it was heated before being placed upon the pump.

The space in this lamp is narrow and long and as the glass of the lamp is always somewhat cooler than the phosphorous vapors, this added to the other difficulties mentioned makes it necessary that the tubular lamps be handled by our most skilled operators.

Lamps with small bulbs are difficult to exhaust for the last-named reason and also because they are so small that it is difficult to avoid vaporizing too much phosphorous. If too much phosphorous is vaporized the bulb of the lamp is discolored. Each size of lamp and each shape of bulb behaves a little differently from any other size or shape of bulb. The two examples are given above as illustrations only.

As the tube, through which the lamp is exhausted, which also carries the phosphorous must necessarily be of a resonable thickness, in order not to collapse when the blow pipe flame is applied to vaporize the phosphorous, it also must possess considerable heat capacity. As often only a very small amount of phosphorous vapor is required for the reaction there is every opportunity for an unskilled operator to use too much phosphorous, thereby making a lamp unsalable. An operator on a small lamp, or on a tubular lamp, or on a lamp in which the reaction is progressing freely, must be especially careful to withdraw the flame from the phosphorous-carrying tube long before the reaction is completed, as the phosphorous will continue to vaporize until the tube has cooled considerably. If an operator is sufficiently skilled, she can tell by watching the progress of the reaction in the lamp bulb as indicated by the changing color and form of the blue light which fills the bulb, when the reaction is about to be completed. A skilled operator will exhaust lamps with almost no rejections from one day to another. Such an operator is always very fast and always produces lamps of high quality. The contrary is true of one who is not skilled.

One reason that an operator who can always quickly vaporize just enough phosphorous and who does not vaporize too much phosphorous produces high-quality lamps is that the voltage at which it is necessary to operate these lamps in order to produce the temperature and the cross currents is such that if a lamp were burned at this temperature for many seconds the lamps would have passed much of its useful life. It is obvious that every second that can be saved when the lamp is being burned at this temperature adds hours to the life which the prospective customer will obtain from this lamp. This assurance that all the lamps exhausted by an expert operator will give practically the same life and candle-hours, other conditions being equal, is of great value.

Under the mercury pump régime the lamps burned not less than twenty minutes each at a voltage not less than 10 per cent. above normal. During only the last few minutes would the vacuum approximate that at which the lamps would ultimately burn. The lamps on the mercury pumps were also burned in addition to this at a voltage at least as high as that ever reached by the chemical methods and for a longer time.

Burning lamps at high incandescence before the vacuum becomes sufficiently good discolors the filaments. This raises the voltage at which the lamps deliver the candle-power for which they are designed, providing a good vacuum is ultimately produced in these lamps. When such lamps are shipped to the customer they are labeled to be operated at higher voltages than would have been the case had the lamps been exhausted by the modern process. In the days of the mercury pumps one of the principal causes for rejection of the lamps from some of the pump room operators was the blackened filaments resulting from this cause. In rejecting lamps for this cause, lamps with filaments only slightly burned were necessarily passed for shipment.

Such lamps would rise rapidly in candles at the beginning of their life and fall almost as rapidly after the first 50 or 100 hours. This condition has been almost entirely eliminated. Much of the improvement in lamp quality in recent years can be traced directly to better methods of exhaustion.

Lamps in which the gases have not been thoroughly eliminated from the joints between the filaments and the platinum wires will fall rapidly in candles when put into service. Much of the rapid decline in candles in the lamps exhausted on mercury pumps was due to the joints between the filament and the platinum discharging gases while in service.

The closer specifications to which modern lamps can be shipped can also be partly traced to this improvement in exhausting as indicated in the preceding paragraphs. When the history of the development of the incandescent lamp is written the most interesting chapters will be those which deal with this portion of the story. Only a very brief outline of the subject has been given above. Many hundreds of experiments and life tests and the expenditure of a great deal of money is summed up in this brief description.

Electric vs. Steam Locomotives.

Discussing the above topic, Mr. E. C. Boynton says, in a recent letter to the *Street Railway Journal:* "The writer, who has some knowledge of both sides of the question—that of the contest for supremacy between the steam and electric locomotive—is of the opinion that the fight has only begun. Certainly most steam engineers are to-day as confident of victory as ever, and do not consider the contest at all one-sided, as our electrical friends seem to think it. The strongest argument of the steam engineers is their contention that they will never be beaten in the long-distance haul. They do not necessarily mean high speed or great mileage per locomotive day, but length of track. They believe that there is a limit to the distance which it would pay to equip with electric traction a railway doing a general freight and passenger business, and in the present state of the electrical art they are right. They are not yet ready to admit defeat even in short-haul suburban passenger traffic, and will await the result of those, to them, experiments which are about to be tried at enormous expense by several railways.

"To one who has watched the improvements in both kinds of locomotives during the past five or six years, it is difficult to decide whether the steam or electric locomotive has improved the faster. The steam locomotive of to-day presents about the same comparison to that of the earlier date as does the modern interurban car to that of six years ago. The improvements in the steam locomotive, as exemplified in the 'Atlantic' and 'Lake Shore' types have been many. They include the wide fire-box, with its immense grate surface, and the increase in size and capacity of the boiler. The boiler pressure has been carried up to 250 pounds per square inch, and the steaming capacity of the boiler, even with poor fuel, has been made sufficient to supply the largest cylinders which could be used with the tractive weight of the engine. The use of the piston valve and the various types of compound cylinders has added greatly to the general efficiency.

"It must not be supposed that this increase in efficiency means higher speed with a decrease in consumption of fuel, water and oil. The steam engineer was not trying to do that, but to reduce the cost per ton-mile hauled, and he has succeeded. He hauls freight and passenger trains of far greater weight than before, and at higher speed at less cost.

"A somewhat mistaken idea has been held by many that the steam locomotive designer is trying to save weight. This is not always so, but frequently railways ordering new power specify the maximum weight, generally on account of the strength of their bridges, and sometimes the weight of their rails."

Government Telephony in France.

A cable dispatch from Paris says: "Drastic proceedings in the telephone administration of Paris, shown in the case of Mlle. Sylviac and others, are exciting a storm of protest in all directions. Among others a meeting has been held at the Palais de Justice at which 200 young lawyers were present. Four speeches were made against the assumption by the government of power to fine subscribers at will, and by 180 votes against 20 the telephone administration was scathingly censured."

Measurement of the Insulation Resistance of an Electric Wiring System.

By Edwin F. Northrup.

The writer recently had occasion to measure the insulation between each bus-bar and the gas pipes of the wiring system of a large city office building at a time and under circumstances where it was not practicable to shut off the power.

The measurement was made by two methods. As these methods are both generally applicable for determining the insulation resistance of each side of any wiring system while the power is on, we have deemed them to be of sufficient value to warrant description.

I.—Voltmeter Method.

Let A (Fig. 1) represent any wiring system in which X_1 and X_2 are the insulation resistances between the bus-bars, B_1 and B_2 and

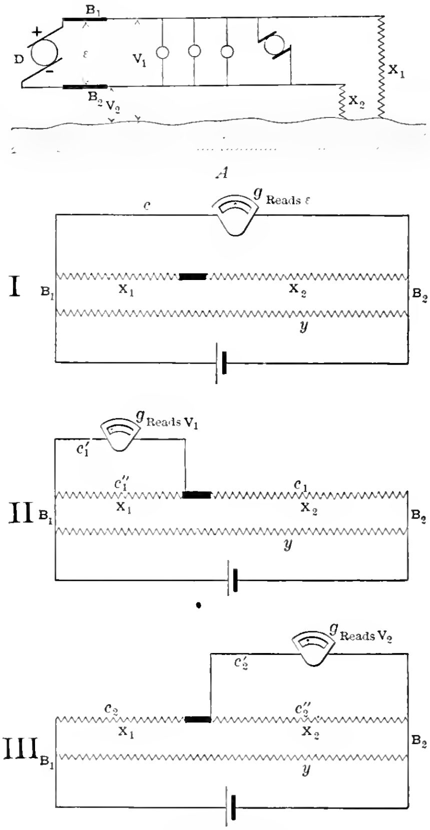


FIG. 1.—VOLTMETER METHOD.

the earth (the gas or water pipes being taken as at the potential of the earth). In Fig. 1, *I, II* and *III* are equivalent diagrams in which y represents the unknown resistance of all the lamps, motors, etc., across the line.

If direct current is supplied to the bus-bars, a Weston direct-current voltmeter should be used. If the current is alternating, then an alternating-current Weston voltmeter will be required. The resistances, X_1 and X_2, are determined by knowing g, the resistance of the voltmeter, and by taking three voltmeter readings.

1st. Measure the voltage, which we will call E, across the bus-bars (Fig. 1) *I*.

2nd. Connect the voltmeter between the bus-bar, B_1, and the earth, and take its reading, which we will call V_1 (Fig. 1) *II*.

3d. Connect the voltmeter between the bus-bar, B_2, and the earth and take its reading, which we will call V_2 (Fig. 1) *III*.

If the readings in either of the two latter cases are only a fraction of a scale division, then the insulation resistance is too high to be measured by this method and we may resort to the second method to be described. Having taken the above three readings, it can be shown that

$$X_1 = \frac{g\ (E - V_1 - V_2)}{V_2} \qquad (1)$$

$$X_2 = \frac{g\ (E - V_1 - V_2)}{V_1} \qquad (2)$$

The current, I, which leaks to the ground will be:

$$I = \frac{E}{X_1 + X_2}$$

In the particular case above referred to, in which the insulation resistance of the wiring system of a large office building was determined by means of a Weston voltmeter, the following readings and resistances were obtained:

g = 12,220 ohms,
E = 113 volts,
V_1 = 1 volt,
V_2 = 4 volts.

$$X_1 = \frac{12{,}220\ (113 - 1 - 4)}{4} = 329{,}940 \text{ ohms,}$$

$$X_2 = \frac{12{,}220\ (113 - 1 - 4)}{1} = 1{,}319{,}760 \text{ ohms.}$$

The above example shows that where the sum of the resistances, X_1 and X_2, are not over one or two million ohms, the voltmeter method is sufficiently accurate for the purpose. If one side of the line is grounded—that is, if $X_2 = 0$—then from (2) $E = V_1 + V_2 = V_1$, as $V_2 = 0$, and the method fails to give X_1.

Expressions (1) and (2) above are obtained as follows: The meaning of the letters used are indicated in *I, II* and *III* (Fig. 1), C_1, C_2, etc., being currents and g the resistance of the voltmeter.

$$C_1 = \frac{E}{X_2 + \dfrac{g X_1}{X_1 + g}},$$

$$C_2 = \frac{E}{X_1 + \dfrac{g X_2}{X_2 + g}},$$

$$C_1{}^1 = \frac{X_1}{g + X_1} C_1 = \frac{V_1}{g}, \quad \text{or} \quad C_1 = \frac{V_1\ (g + X_1)}{X_1\ g},$$

$$C_2{}^1 = \frac{X_2}{g + X_2} C_2 = \frac{V_2}{g}, \quad \text{or} \quad C_2 = \frac{V_2\ (g + X_2)}{X_2\ g}.$$

Hence, we have the two relations,

$$\frac{E}{X_2 + \dfrac{g X_1}{X_1 + g}} = \frac{V_1 (g + X_1)}{X_1 g}, \quad \text{and} \quad \frac{E}{X_1 + \dfrac{g X_2}{X_2 + g}} = \frac{V_2 (g + X_2)}{X_2 g},$$

from which the values for X_1 and X_2 are obtained as given above in equations (1) and (2).

Any instrument, as a galvanometer, in which the deflections are proportional to the currents may be substituted for a voltmeter. In such a case, if D, d_1 and d_2 are deflections corresponding to the readings E, V_1 and V_2, and G is the total resistance in series with the instrument, we have as before:

$$X_1 = \frac{G\ (D - d_1 - d_2)}{d_2} \qquad (3)$$

and

$$X_2 = \frac{G\ (D - d_1 - d_2)}{d_1} \qquad (4)$$

If two or more electric lamps are connected in series, their resistances, while carrying current, can be determined by means of three readings, as above.

If $X_2 = \infty$, $V_1 = 0$, and $X_1 = \frac{g\ (E - V_2)}{V_2}$, which is the ordinary expression used in measuring a resistance with a voltmeter by reading the voltmeter with the resistance in series with it and again with the resistance cut out.

II.—GALVANOMETER METHOD.

This method may be used when greater accuracy is required or when the insulation resistance to earth, of at least one side of the line, is over a megohm.

The wiring system is represented in 1 of Fig. 2, and 2 of Fig. 2 gives equivalent circuits.

The method consists in connecting across the bus-bars a mod-

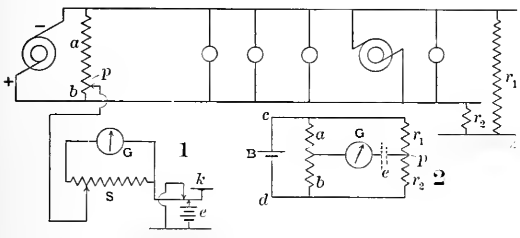

FIG. 2.—GALVANOMETER METHOD.

erately high resistance and finding on this resistance a point, p, where the potential due to the generator is the same as that of the earth, and then with the aid of a sensitive galvanometer and an external source of e.m.f., measuring the resistances, r_1 and r_2, to earth in the following manner: k is a key and S an Ayrton universal shunt. This latter may be omitted if the source of e.m.f. can be varied in a known manner.

It is evident from Fig. 2 that a balance will be had when $\frac{a}{b} = \frac{r_1}{r_2}$, the key, k, being in its upper position. If k is now depressed, the resistance, R, encountered by the current generated by the source, e, will be

$$R = g_1 + \frac{1}{\frac{1}{b + r_2} + \frac{1}{a + r_1}}$$

where g_1 is the resistance of the galvanometer; but in comparison with r_1 and r_2, g_1, a and b can be neglected, and

$$R = \frac{r_1\ r_2}{r_1 + r_2}.$$

By construction, $\frac{r_1}{r_2} = \frac{a}{b} = N$, a known ratio. From the last two relations we deduce

$$r_2 = \frac{R\ (N + 1)}{N}$$

and

$$r_1 = R\ (N + 1)$$

Taking d as the deflection of the galvanometer and K as the galvanometer constant, the current through the galvanometer is $\frac{e}{R} = \frac{d}{K}$, or $R = \frac{e K}{d}$.

K should be defined as the resistance which must be inserted in circuit with the galvanometer (including its own resistance), so that it will give, with one volt, a scale deflection of one scale division at the distance at which the scale is placed from the mirror during the test, usually taken as one meter.

Then we will have:

$$r_2 = \frac{e K\ (N + 1)}{N d}$$

and

$$r_1 = \frac{e K\ (N + 1)}{d}.$$

Taking $K = 10^8$ as an average value for an ordinary D'Arsonval galvanometer and $e = 100$, $n = 2$, and $d = 100$, we have:

$$r_2 = \frac{100 \times 10^8\ (2 + 1)}{2 \times 100} = 150 \text{ megohms,}$$

$$r_1 = \frac{100 \times 10^8\ (2 + 1)}{100} = 300 \text{ megohms.}$$

This example shows that a galvanometer of very moderate sensibility will measure in this way a very high insulation resistance. If, on the other hand, the insulation is low, small battery power may be used or the deflection of the galvanometer can be cut down to 1/10, 1/100, 1/1000 or 1/10000 by the Ayrton shunt. The only difficulty likely to be experienced in applying the above method is that, while making the test, the relative values of r_1 and r_2 will keep changing, due to motors or lights being thrown on or off the line. In this event it is only possible to obtain a sort of average value for the resistance to earth of each side of the line.

Evidence by Telephone.

The following is a suggestive comment by the New York *Times* on the receiving of evidence by telephone: "A notable incident of an otherwise uninteresting murder trial now going on in this city followed an attempt by the prosecuting attorney to utilize a means of communication that is considered, outside of court rooms, perfectly satisfactory for almost every purpose, including many of the greatest importance. The prisoner had testified that he had owned the revolver with which he did the killing—in self-defense, he asserted—since 1901, while the prosecution, having noted the number on the weapon, had learned from its manufacturers that it was made in 1903. This information, with its obvious bearing on the prisoner's credibility, and, in a slighter degree, on the question of premeditation, had been obtained by long-distance telephone during a recess of the court, and the prosecutor naturally wanted to get it before the jurymen. He therefore proposed the immediate installation of a telephone in the court room, in order that the jury might hear a repetition of his inquiries about the pistol and the manufacturers' replies. This plan was in complete accord with the habitual conduct of business affairs at the present time, and its convenience and economy would have recommended it to any layman desirous merely of ascertaining a needed fact, quickly and correctly. Telephones, however, were invented some years since the rules of procedure in murder trials were established, and no sooner had the suggestion been made than the prisoner's counsel leaped to his feet with a vehement objection, based on the fine old principle that it is a defendant's constitutional right to be confronted by the witnesses against him. Of course the judge held that the objection was well taken and the telephone plan had to be abandoned. The question of the pistol's age was of no particular consequence, and perhaps the prosecutor made his point with the jury about as well as if he had been allowed to do what he desired, but the episode illustrates again the curious inharmony between court methods and principles of action and those accepted and followed in the ordinary relations of life."

The Protection of Telephone or Telegraph Lines When in Hazardous Proximity to High Tension Lines.

By Robert E. Chetwood, Jr.

There appeared recently in this paper an article by Howard S. Knowlton entitled "The Prevention of Crosses Between Signalling and High-Voltage Circuits," the principal features of which were descriptions and illustrations of what are commonly termed "short span" crossings. The descriptions and illustrations given by Mr. Knowlton were those originally contained in specifications, now obsolete, which were prepared by one of the leading Bell telephone companies at the time when it first became necessary to make provision for the crossing of high-tension and telephone lines. Since these specifications, which form the basis of Mr. Knowlton's article, were issued, the increase in the number of both telephone and high-voltage lines has been so rapid that the entire subject of the protection of telephone circuits when in proximity to high-voltage wires has been carefully studied and various types of protected crossings designed. It is the purpose of this article to describe several types of protected crossings in the design of which the writer has been identified.

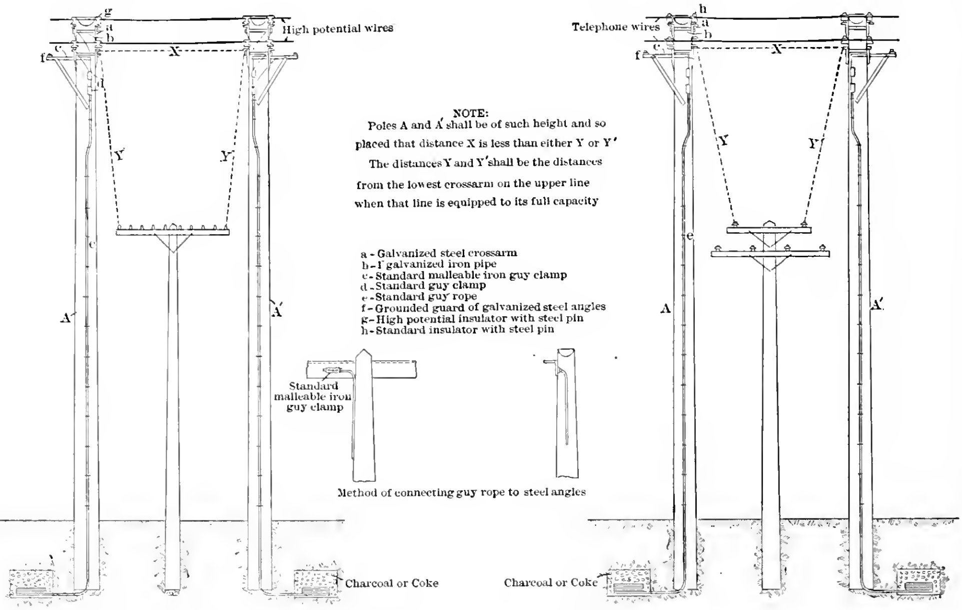
In Figs. 1 and 2 are shown the construction of short span crossings, Fig. 1 illustrating a short span in the high-tension line and Fig. 2 showing a short span in the telephone line. It will be readily seen that the construction illustrated, while embodying the fundamental feature, differs radically in the details from those described in the article referred to. The short span crossings described by Mr. Knowlton failed to provide any protection against one of the greatest and most frequent sources of danger, namely, the puncturing of the insulators on the high-tension line, resulting generally in the burning through of the wooden cross arm, thus allowing the high-tension wire to come into contact with the wires of the telephone line crossing below.

In the construction illustrated in Fig. 1, the cross arms and pins are of galvanized steel angles and are grounded by means of a galvanized-wire rope of ample current-carrying capacity for the line in question. Besides the use of grounded steel pins and cross arms the poles forming the short span are fitted with an extension guard of galvanized steel angles. This guard projects out from the pole about eighteen inches and is two feet longer than any cross arm, the object being that in the event of a wire breaking in an adjacent span it will be in contact with this grounded guard before and at the time it may swing into contact with the wires of the line below.

Other details in which it differs from the construction recommended by Mr. Knowlton is that it requires the poles of the short span to be double-armed and the line wires securely tied to the insulators on the arms. The dead-ending of heavy high-tension wires and completing the circuit by means of a loop is not considered good practice, inasmuch as the power wires are likely to be injured in dead-ending. The construction also requires the outside wires on the cross arms of the short span to be tied to the inside or pole side of the insulators, in order that in the event of tie wires breaking or unrolling, the line wires will be held on the grounded cross arms by means of the steel pins.

The method of grounding the wire ropes, as shown in the figure, is to make their ends up into coils of at least six turns and not less than eighteen inches in diameter and to bury them at or near the base of the poles. The holes in which the coils are placed should be not less than six feet deep and should be dug until moist earth is reached. Over the coils is dumped three bushels of fine charcoal or coke. In some instances it will be necessary to carry the wire ropes some distance from the base of the poles in order to obtain a good ground connection.

The short span type of crossing for high-voltage and telephone lines is undoubtedly the most desirable one and the short span



Figs. 1 and 2.—Construction of Short Spans at Crossings with High-Potential Lines.

should, if possible, be constructed in the high-tension line. To assist in obtaining a short span crossing with the short span in the high-voltage line, the spacing of the pins on the telephone cross arms can be reduced so that a six-foot cross arm may be used instead of the standard ten-foot arm. This, of course, will allow of a shorter span, and, therefore, shorter poles in the power line.

A crossing constructed as above is as near safe as it is possible to conceive. If it is found impossible to make the crossing with the power line overhead, by using the same precautions, the telephone or telegraph line can be the overhead line.

While the short span method of crossing is the ideal method it so happens that in the majority of cases the crossing comes at the intersection of streets or roads where the conditions would require the use of poles of such a height and such guying rights as to render the method obviously impossible. The best method of crossing under these conditions is to have the high-tension line cross over the telephone or telegraph line and to protect the lower line, as shown in Fig. 3.

This protection consists in stringing between the poles of the telephone line, as close to their tops as is possible, a grounded steel rope of such size that it will safely carry at least three times the normal current in the power wires, and below this grounded rope of placing an insulated screen of 12 No. 6 B. W. G. galvanized-iron wires. The telephone line wires are then carried as usual on cross arms located below the arms carrying the screen of No. 6 wires.

The action of such protection is as follows: The grounded rope, being of such size that it will safely carry three times the normal current in the power wires, will generally be between one and one-half and two times the diameter of the power wire; in fact a good rule to follow is to select a size of rope that is one and a half times the diameter of the power wire. In case a power wire breaks or sags, this grounded rope will be directly in its path and the contact between the two, depending of course upon the type of the transmission system involved, will or will not operate the safety devices at the power station. It will in any event probably lower the voltage on the power wires and render it incapable of doing any damage to the telephone wires.

It is also extremely probable that the grounded rope will fuse the power wire whenever an arc is formed between this wire and the grounded rope. It is believed that it is the heat generated by the arc rather than the amount of current that flows that will cause fusing. That being the case, the grounded rope, being of iron or steel, having a higher fusing temperature than copper or aluminum and having a greater radiating surface, will probably fuse the high-tension wire, allowing it to fall harmlessly to the ground. The insulated screen of 12 No. 6 B. W. G. galvanized wires, which extends a foot on each side beyond the telephone wires, serves as an additional protection to the telephone or telegraph wires while the power wire is in contact with the galvanized rope or after it has been fused by this rope.

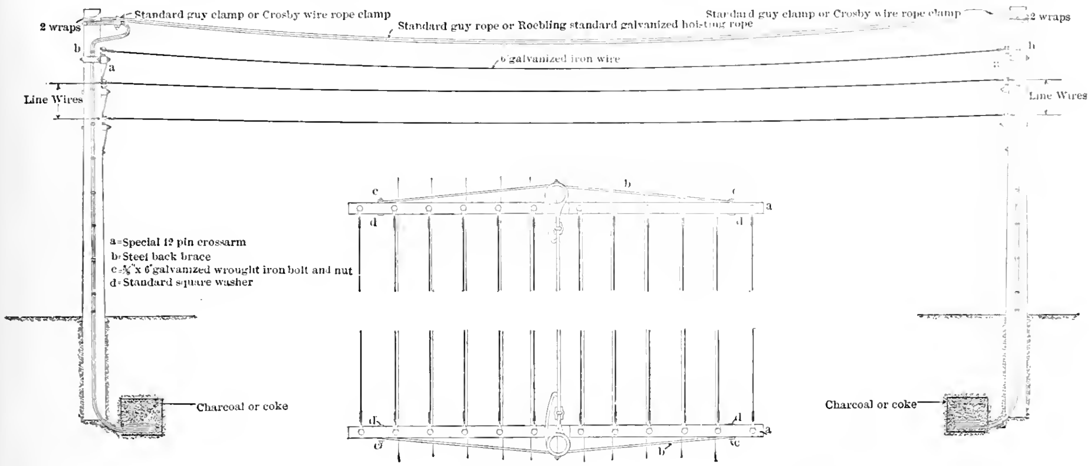


Fig. 3.—Protection for Telephone Wires Crossing Under High-Potential Wires.

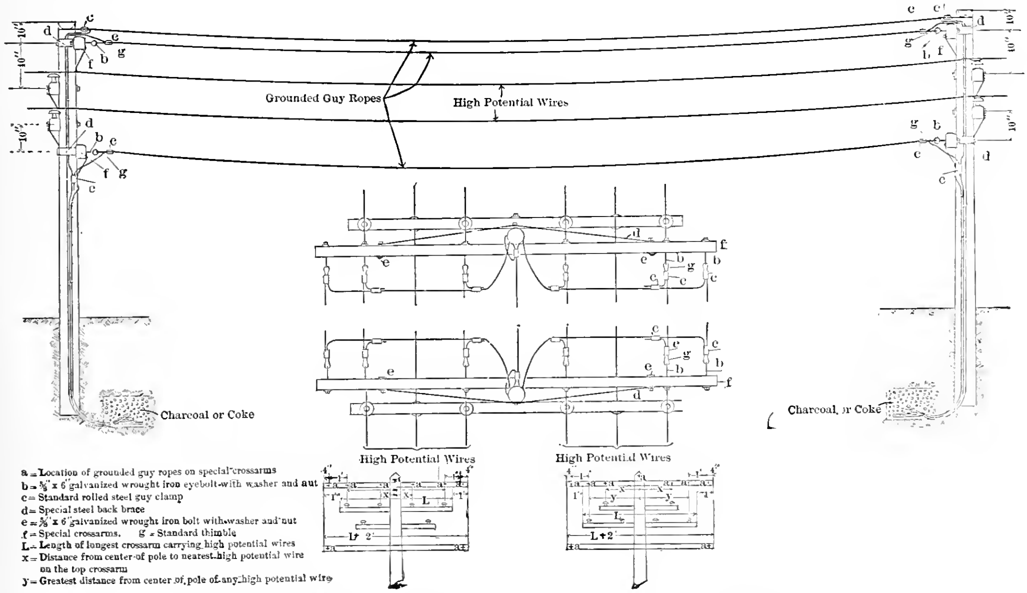

Fig. 4.—Protection for Telephone Wires Crossing over High-Potential Wires.

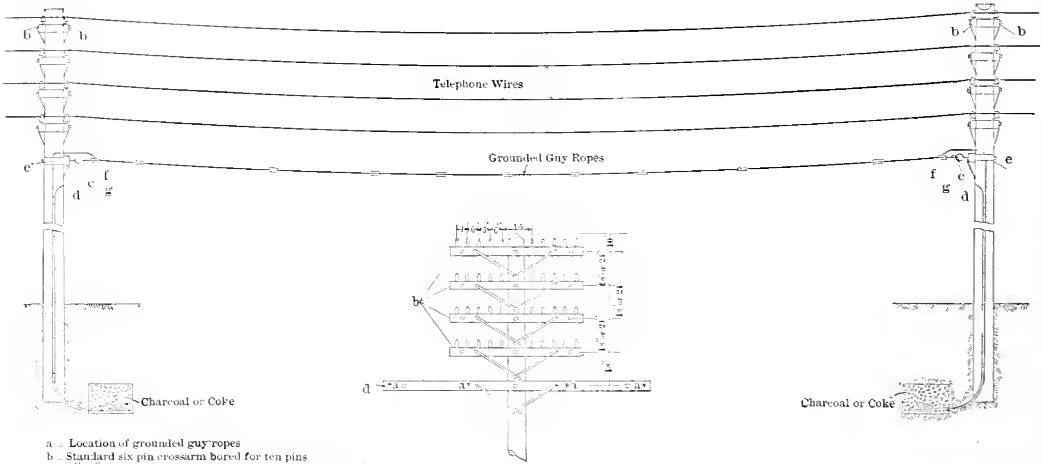
Of course the efficiency of the grounded rope depends greatly on the ground connection secured, and this part of the construction should be given great attention. In general a good ground can be obtained as previously described, but in some cases extraordinary measures must be taken to make sure of a permanent and perfect ground connection.

When, due to excessive cost or to local conditions, it is impossible to make a short span crossing, and, furthermore, it is necessary for the telephone or telegraph line to cross above the high-voltage line, the crossing should be protected as shown in Fig. 4, where the protection is placed on the high-potential line, or as shown in Figs. 5 and 6, where the protection is placed on the telephone line.



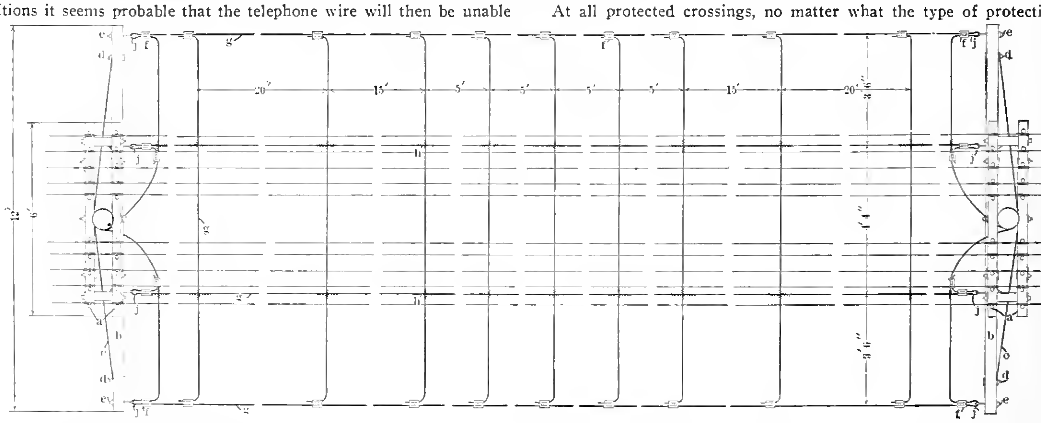
a = Location of grounded guy ropes
b = Standard six pin crossarm bored for ten pins
c = ⅝" x 6" galvanized wrought iron eyebolt with washer and nut
d = Special 12' crossarm
e = Steel back brace
f = Standard rolled steel guy clamp
g = Standard thimble

FIG. 5.—SIDE VIEW OF PROTECTION FOR TELEPHONE WIRES CROSSING OVER HIGH-POTENTIAL WIRES.

The protection shown in Fig. 4 consists of placing on the power line grounded wire ropes, so situated that a telephone or telegraph wire in falling will be in contact with a grounded rope before and at the time of contact with a high-potential wire. Under such conditions it seems probable that the telephone wire will then be unable to transmit any voltage of a dangerous value past the point of contact with the grounded rope. This grounded rope must, of course, be of such size as will insure the fusing of the telephone or telegraph wire and which will also carry without fusing several times the normal current carried by the power wire.

The location of the grounded ropes should be determined as shown in Fig. 4, and the construction should be mechanically strong. It is obvious that the power line must be dead at the time such protection is installed, a condition that is sometimes hard to meet. The details of the construction are sufficiently well illustrated by the figure to need no further comment.

In Figs. 5 and 6 are given two views of the type of protection that should be used when it must be located on the telephone or telegraph line. It consists of a grounded net situated directly below the telephone wires and with which a telephone wire must be in contact before and at the time it comes in contact with a high-potential wire on a line crossing under the telephone line at right angles. The construction involved is readily understood from the figures.



a = Standard six pin crossarm bored for ten pins
b = Special twelve foot crossarm
c = Steel back brace
d = ⅝" x 6' galvanized wrought iron bolt with washer and nut
e = " " " " Eyebolt " " " "
f Standard rolled steel guy clump
g = Standard guy rope
h = 6 galvanized iron wire
j = Standard thimble

FIG. 6.—TOP VIEW OF PROTECTION FOR TELEPHONE WIRES CROSSING OVER HIGH-POTENTIAL WIRES.

At all protected crossings, no matter what the type of protection may be, the poles of both lines should be specially selected in regard to strength and should be so guyer as will make their breaking or falling well nigh impossible. The guys attached to the poles of both lines should be grounded and the insertion of suitable strain insulators in the guys attached to the telephone line at or near the telephone poles is recommended as an additional measure of safety. In no case should the guys of one line be attached to the poles of the other line.

The above methods of protecting telephone or telegraph lines at points where they come into hazardous proximity to high-tension lines are those in use by one of the largest Bell Telephone companies. They are the result of considerable study and have been constructed at a number of crossings. While the expense of the construction, especially in making short span crossings, has been considerable, the measure of safety that has been procured not only to their own property but to that of their patrons overbalances any consideration of expense.

Electrical Illumination of the Louisiana Purchase Exposition.

By CLOYD MARSHALL.

THE spectacular effects which make one exposition more notable than its predecessor, are due largely to electric lighting. Electrical engineers have learned much about illuminating effects from expositions, for nowhere else are presented the problems of brilliantly lighting such great areas, both indoors and out. After much discussion and experiment it has been decided that the most satisfactory result of illuminating the grounds and architecture, can be secured by the use of incandescent lamps alone. By spacing the lamps at short intervals, the effect is a line of light marking each architectural outline. Within the buildings the result derived is wholly different, for the light must be such that the visitors can examine minute details, and read inscriptions anywhere. Arc lights of high candle-power, with suitable reflectors, give, in general, the best results.

The lighting at the Louisiana Purchase Exposition has been carried out on this general plan. The area of the Exposition grounds is about two square miles, of which the buildings cover approximately 130 acres, and it has been a herculean task to properly light so great an area.

The main picture of the Exposition, embracing the Grand Basin, the Plaza of St. Louis, Festival Hall, the Colonnade of States, the Electricity, Education, Manufacturers' and Varied Industries Buildings, has been lavishly festooned with electric lights. Festival Hall, with its dome rising 325 ft. above the Plaza, is marked in every outline with incandescent lamps. There are two flanking colonnades extending in an arc a quarter of a mile in length, terminating in a pavilion at either end. Each light unit on the colonnade consists of three incandescent lamps, white, amethyst and emerald, which, by means of the regulating devices, give beautiful color effects. About 20,000 lamps are used to make this a crowning feature. All cornice lines, columns, the vertical lines of the corners and main entrances, and all architectural decorations of the surrounding buildings, are marked with incandescent lamps, spaced 15 in. centers. Around the Grand Basin and lagoons are railings supported by ornamental lamp posts, as shown in the illustration. Sixty 8-cp incandescent lamps are carried on each post, and Meridian lamps are supported by the four arms.

All the central buildings have colonnades, which are even more beautiful by night than in the day time. At the rear of each column is a vertical line of lamp. The light striking the building walls behind brings the columns in sharp outline against a bright background. The outlines of the other buildings are more subdued than the brilliant spectacle around the Grand Basin, yet at night the whole Exposition appears as a city of light; and this will doubtless appeal to the imagination of the greatest number of visitors.

Power sufficient for this purpose had to be secured from three sources, an exhibitors' power plant, consisting of about fifteen direct-connected units ranging from 400 to 5,000 hp each; the Westinghouse service plant of four 2,800-hp units, and 7,500 kw to be rented from the Union Light & Power Company, of St. Louis. Of this 10,000 hp is to be used for lighting alone.

From the switchboard in the west end of the Machinery Hall mains extend through the conduits to the various sub-stations about the grounds. These conduits consist of pump log ducts which were familiar to the engineer in years gone by, but to-day are almost a curiosity. However, for a year's service these will answer the purpose very well and will likely never be removed from the trenches. The trenches are lined with boards and the ducts having a square cross-section can be placed in number suitable to accommodate the circuits. Under the lagoons the ducts are laid in cement. Manholes of timber construction are placed at convenient intervals along the principal thoroughfares. For power and lighting lead-covered cables are used, and these will be removed for further service after the Exposition. All telephone, telegraph and other wires about the grounds are carried in these same ducts, and no wires of any description are overhead.

The power supply is a 6,600-volt, three-phase current, direct from the large generators to the step-down transformers in the sub-stations. The one in Electricity Building is a typical installation. The mains reach the switchboard through the conduits and to the primaries of the twelve transformers. Three are General Electric oil-cooled, 100-kw, three-phase transformers, giving a secondary voltage of 110 volts for power within the building. The three larger General Electric 250-kw transformers with a secondary of 110 volts furnish power for decorative lighting on the outside of the building. The 200-kw Westinghouse rotary converter is supplied from three 75-kw transformers at 388 volts, and delivers 550 volts direct current for power to operate exhibits. Two motor-generators of 100 kw each supply an Edison three-wire system throughout the building. Insulated cables are carried up from the sub-station switchboard, and extend entirely around the building, supported by porcelain insulators on the trusses. Different circuits are tapped in as the exhibitors may need for power or light, and the wires are supported on cleats attached to the girders. These run to a post in the exhibitors' space and down to a switchboard.

For decorative lighting the cables run to the roof of the building. On the balustrade above the cornice line are switchboards, and from these the lighting feeders extend around the entire circumference of the building. The small circuits are connected at convenient points and run to the columns, flag staffs, or along the cornice line. The wiring is concealed where its presence would detract from the appearance of the structure, and in such places rubber-covered wire only has been used, and is brought to the surface through porcelain tubes. In such cases the sockets are attached to the woodwork and

FIG. I.—COLUMN ALONGSIDE OF LAGOON.

embedded in the staff so as to appear a portion of the column or ornament. This work has been done since last summer and fall and to prevent deterioration during the winter the sockets were filled with a tar composition which was readily removed before the lamps were put in place. Along the cornice lines and other places too remote to notice the circuits are carried on porcelain cleats, and in such cases slow-burning weather-proof insulation was used.

The arc lights within the building are in series on a 3,500-volt, 50-cycle circuit. Except in the Electricity Building, the sub-stations are enclosed in brick structures to reduce the fire risk to a minimum. Although all this work is for temporary purposes only, it has been so well planned and executed that when the lights were turned on and the circuits tested, not one serious flaw was found.

One of the interesting and novel features of the interior lighting is the application of Nernst lamps on a large scale to the lighting of the fine arts exhibit. In arriving at the decision to adopt the Nernst lamp, the art gallery officials made careful tests to determine the practical value of its advantages in this field of lighting, namely, white quality, steadiness and economy. In addition, it was claimed that owing to the downward distribution of the light, a great uniformity of illumination would be secured over the wall space usually occupied by an art exhibit, the weaker rays being in the direction of the upper and the nearer portions of the wall, and the stronger rays

ELECTRICAL ILLUMINATION AT THE LOUISIANA PURCHASE EXPOSITION.

in the direction of the lower and more distant portions. Where the exhibits occupy the walls exclusively, the uniformity and intensity of the wall illumination is greatly improved by the use of a specially designed reflector on each lamp, similar to that shown in Figs. 1 and 2.

This reflector is of light, rigid construction and is fastened to

FIG. 8.—NERNST LAMP WITH REFLECTOR FOR ART GALLERY.

and supported by the lamp, in the same manner as the standard shade. Of course, this reflector also acts as a shield, preventing

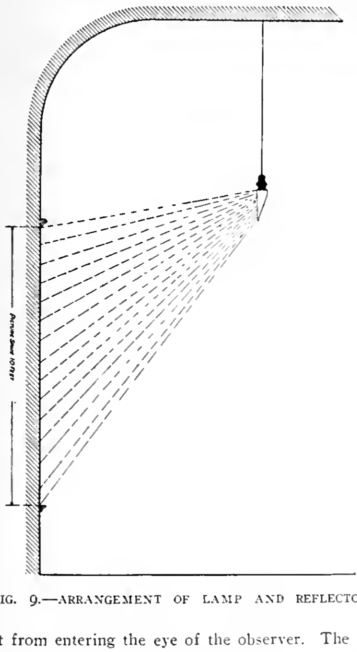

FIG. 9.—ARRANGEMENT OF LAMP AND REFLECTOR.

direct light from entering the eye of the observer. The preliminary tests which were made using this reflector and under conditions approximating as near as practicable the actual art gallery conditions, were attended with very satisfactory results.

The plans involve the use of 1,541 Nernst lamps of different sizes, making a total of 4,780 glower units, with a total consumption of

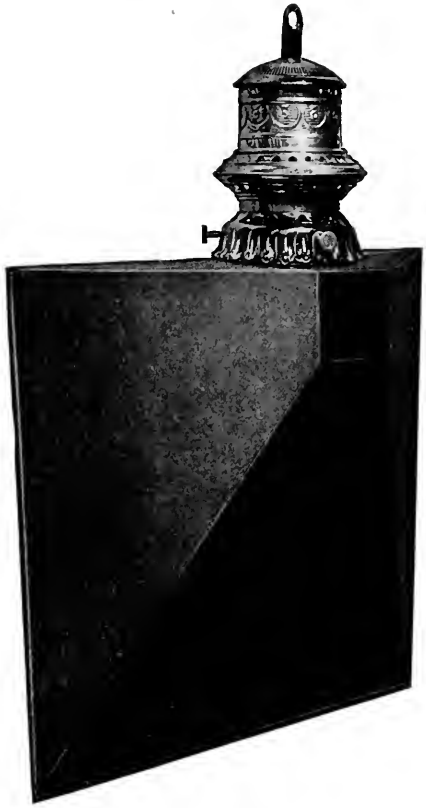

FIG. 10.—NERNST LAMP REFLECTOR FOR ART GALLERY.

401,520 watts. The sculpture halls will be lighted by means of large clusters, each consisting of 19 six-glower lamps at 60 ft. elevation. In the art gallery section the three-glower lamp, with the special reflector will be the standard unit, these being arranged around the four sides of the room 8 ft. from the wall, as shown in the cut. The lamps will all be supplied with 25-cycle current from a single-phase, 210-volt circuit, a portion of the load on the latter being used for power purposes.

New Hudson River Tunnels.

The New York State Board of Railroad Commissioners last week granted a certificate of public necessity to the Hudson & Manhattan Railroad Company to build two single-track tunnels under the Hudson River from Church Street, between Cortlandt and Fulton Streets, New York, to Exchange Place, Jersey City. It is stated that the company has bought the western part of two blocks bounded by Church, Fulton and Cortlandt Streets and Broadway. The Havemeyer Building occupies one of these plots.

The two tunnels will form a continuous loop. The south tunnel will come from the river under Pier 13 and Cortlandt Street to the loop station at Church Street, running around into the north tunnel under Fulton Street and Pier 14. From the terminus there will be a footway under Dey Street to Broadway and the subway station there and up to Broadway and John Street, the passageway being under the subway level. A very comprehensive system of connections with existing and developing lines of communication is contemplated by the plans.

The Magnetite Arc Lamp.

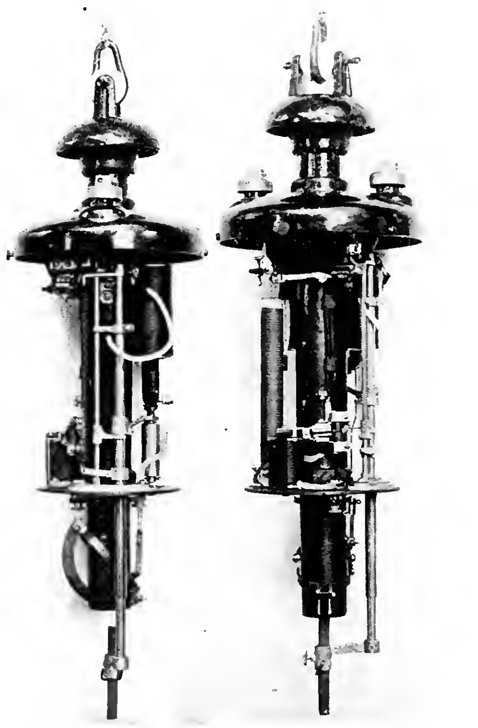
By Charles Proteus Steinmetz.

WHILE in the transformation of electric into mechanical power very high efficiencies are reached, values of 90 per cent. to 95 per cent. being quite common, the efficiencies of the present method of producing light from electric energy are extremely low, only about 2 per cent. in the incandescent lamp, perhaps 5 per cent. in the arc lamp. The reason hereof is to be found in the use of heat as an intermediary form of energy, which always leads to low efficiency. To study the methods of producing light from the point of view of developing more efficient methods, some years ago an electrochemical laboratory was established by the General Electric Company and one of the results of the work of this laboratory is represented in the magnetite arc lamp.

The most efficient illuminant heretofore known was the carbon arc, but its efficiency is due to the extremely high temperature, and, therefore, great brilliancy of the incandescent crater of the carbon; and very little light is produced by the arc flame and that of a rather undesirable violet color.

Improvements in efficiency have been made in the last years by adding metal salts as calcium-fluoride to the carbon, which evaporate in the arc, making it luminous and so increase the efficiency, but since all such substances produce a smoke or dust, which has to be disposed of, the carbon cannot be enclosed air-tight and the flame carbons, therefore, give a short burning arc requiring frequent trimming.

In these flame carbons, on which a considerable amount of work



FIGS. 1 AND 2.—3½-AMPERE LUMINOUS ARC LAMP.

was done, the arc-coloring substance is added to the positive terminal as the hottest, from which evaporation takes place more rapidly than from the negative. When used in this manner only calcium compounds seem to give a very good efficiency, and they are mostly used. Their light, however, is of a reddish yellow hue.

Even with its much greater efficiency, due to the short life and the yellow color, the flame carbon arcs do not seem to me to quite meet the requirements of an illuminant able to compete with the enclosed arc of to-day for general illumination, but as the first fundamental condition to be met by an illuminant which should be superior to the present arc lamp for general illumination, I consider besides very high efficiency, long life and white color of the light. While variously colored lights may find some application for decorative purposes, for general illumination, for replacing the daylight during the night, a white light is most desirable, even necessary wherever color values have to be judged.

The condition of long life, with an open arc, excludes the use of carbon in the electrodes and some other carrier of the current in the arc flame must be found. The material which in an arc lamp electrode, by replacing the carbon used at present, would constitute an essential advance in the art of illumination, must, therefore, fulfill the following conditions:

It must be a good conductor when solid and its vapors must be conductors of the arc.

It must be incombustible so as to give a long burning arc.

It must give a spectrum of high brilliancy; that is, an arc of high efficiency.

The light must be distributed approximately uniformly over the whole spectrum; that is, it must give a white light.

In magnetite, or the black oxide of iron, one of the most common iron ores, a substance was found having the required characteristics.

By very extensive investigations of the phenomena taking place in the electric arc with different materials as arc terminals, it was found that the material which carries the arc flame issues from the negative terminal as a high velocity blast which, when striking the

FIG. 3.—MAGNETITE ARC.

positive, produces heat. If, therefore, the positive terminal cannot conduct this heat away, it may get hotter than the negative and does so in the carbon arc.

Therefore, in the carbon arc the positive terminal burns away more rapidly. The greater heat produced at the positive terminal is the reason for introducing arc-coloring substances in the flame carbon arc lamps into the positive electrode. They are introduced into the arc by evaporation, and at the hotter positive electrode evaporation is more rapid. This also has led to the misconception that the positive terminal feeds the arc while in reality it has no direct influence on the phenomena in the arc, but the spectrum of the arc is that of the negative terminal, except where material of a boiling point lower than the temperature of the arc flame is introduced into the arc.

If the positive terminal is made large enough and a good conductor of heat so as to carry away the heat, it does not wear away, but material from the negative terminal deposits on the positive, as drops of magnetite on the copper positive of the magnetite arc lamp if the latter is too large. By giving the positive terminal, therefore, a sufficient heat conductivity not to get too hot, but sufficiently hot to avoid the deposition of material on it, a non-consuming positive electrode is produced. This is the case in the magnetite arc lamp. In this only the negative or lower electrode consists of magnetite, and is consumed. The positive terminal is not replaced, but is a copper segment, which constitutes a permanent part of the lamp.

The metals of the iron group yield a brilliant arc flame of very high efficiency and white color. To give a long life the metals which are combustible are not well suited, but a stable oxide of these metals must be used; that is, a compound which cannot burn any more. Amongst the conducting oxides, magnetite fulfils best the requirements of a carrier of the arc flame, since it is well conducting, stable at all temperatures, very plentiful in nature, and gives a white arc of high efficiency.

Pure magnetite, however, is not quite satisfactory, since its efficiency is not very high, hardly twice as high as that of the ordinary carbon arc; and the arc tends to flicker and the rate of consumption of the electrode is rather high; as high as 1/8 in. per hour. This, while very much lower than the rate of consumption of flame carbons, of 1 in. to 2 in. per hour, would still give only 50 to 60 hours' life with the standard size of electrode adopted for the magnetite arc lamp, of 8 in. length. Therefore, with the magnetite as carrier of the arc flame are incorporated other substances in small quantities as arc-steadying compounds—titanium compounds for increasing the efficiency, etc.

In the manufacture of these magnetite arc electrodes, by partially reducing the material to metal, a greater density is produced and so a

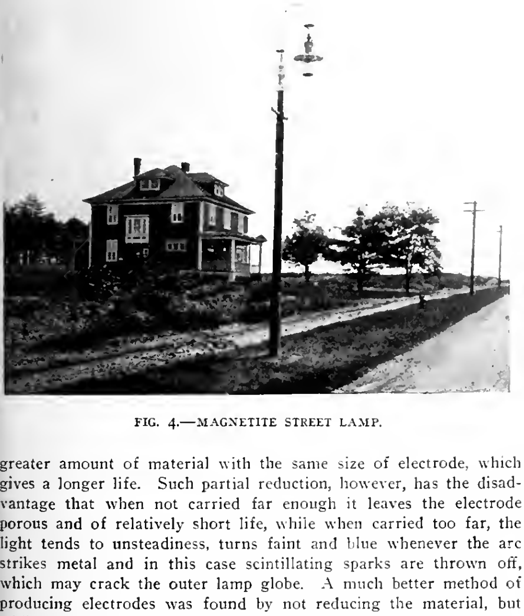


FIG. 4.—MAGNETITE STREET LAMP.

greater amount of material with the same size of electrode, which gives a longer life. Such partial reduction, however, has the disadvantage that when not carried far enough it leaves the electrode porous and of relatively short life, while when carried too far, the light tends to unsteadiness, turns faint and blue whenever the arc strikes metal and in this case scintillating sparks are thrown off, which may crack the outer lamp globe. A much better method of producing electrodes was found by not reducing the material, but adding a restrainer; that is, a substance which added to the electrode material in small quantities reduces the rate of consumption. Hereby, without any loss of efficiency, rates of consumption of 20 to 30 hours per inch are produced, which give a life of 150 to 200 hours for the 8-in. electrode. With very little sacrifice of efficiency a life of 500 to 600 hours is produced and such an electrode has about the same life as an incandescent lamp; that is, the arc lamp requires trimming about as often as an incandescent lamp requires renewal. This latter feature, however, while obviously valuable in cases where trimming is difficult, as with lamps in inaccessible places or during protracted strikes, etc., for general illumination is hardly needed, since it would in street lighting give a life of two months; and a street lamp should be looked after oftener than this.

A simple and satisfactory form is an electrode in which the material is compressed as impalpable powder in a thin iron tube, which is then sealed over by the arc.

In the carbon arc lamp the light comes from the incandescent crater of the positive carbon and not from the arc flame. Hence, the arc lengths should be made as short as possible without obstructing the escape of light from the crater. In the magnetite arc, however, no light issues from the terminals, but all the light comes from the arc flame, and an arc length from 3/4 to 1 1/8 in. is, therefore, most efficient. Furthermore, to give a constant volume of light the arc lengths should be constant. This leads to a feeding mechanism differing from the "floating system" of the carbon arc lamp and much simpler; that is, a feeding device maintaining constant arc length. The operation of the magnetite arc lamp is, therefore, as follows: When the power is put on the lamp, the arc is struck by separating the electrodes to a definite distance, say 7/8 in., and then the electrodes are locked in this position and remain fixed until after some hours or so, by the consumption of the negative electrode, the arc length and thereby the arc voltage has increased sufficiently to operate the feeding mechanism which resets the arc to its original length.

Insurance Features of Street Railway Property.

An important and interesting brochure has been issued by the committee on special hazards and fire record of the National Fire Protection Association devoted to the subject of insurance of street railway property—car barns, car houses, rolling stock, etc. A number of contributors furnish articles and discussions bearing on the topic and several fires are analyzed in detail. The pamphlet is one of 42 quarto pages. Mr. S. H. Lockett, manager of the Insurance Survey Bureau, of Chicago, has a separate article on "Street Railway Property," in which a number of points are discussed. In his introductory remarks he says:

Losses in this class have attracted a great deal of attention to it, and a few words regarding the business may not be amiss. The days of the old horse car are so nearly numbered that horse car barns and systems are hardly worthy of consideration as a class. Indeed, cable lines are also fast disappearing, or, at least, are numerically and in value unimportant as compared to electric, so that underwriters will have to concern themselves principally with trolley and storage battery systems in the future. The retirement of horse and cable systems, however, will have its effect for some time upon the moral hazard of the entire class, and the acceptance of the surviving cable and horse systems, or such systems undergoing a transition to electric motive power, should involve the consideration of many facts. It must not be overlooked also that the adaptation of old systems to new conditions has as well an appreciable effect upon the physical hazard of the class. Large first cost makes the installation of new cable lines rare, and, owing to the increasing difficulties in municipal streets, this first cost is augmenting to such an extent that the building of cable lines is uninviting as a business proposition. This being true, the second-hand value of cable cars is becoming less, and there is a patent moral hazard attached to their insurance. Physically, there has been a marked unsuitability of old horse car barns for electric car storage purposes. This has been due to several facts. Electric cars are larger and longer, necessitating different track and post arrangements. They are also more numerous on the same lines, since traffic has increased with the greater speed and consequent mileage coverable, and the old barns proved too small. Again, the repairs on electric cars are more frequent than in the case of horse cars, owing to the greater number and size of horse cars, as well as their speed, longer travel and the constant increase of general urban and municipal traffic, which are bound to make wear and tear and accidents more excessive. These repairs have resulted in many new processes and hazards which cannot be accommodated in the old buildings. Yet again, owners themselves have appreciated the undesirability of exposing larger values in the later cars to the ill arrangements and poor construction of the old barns which, in many cases, were converted to car barns during the precarious infancy of street traction enterprises. To a somewhat less extent the above remarks are true of cable systems. There is still much poor construction in progress, more particularly in the case of interurban systems handicapped financially and banking on the future increase of business between growing communities, but it will be found that the record of street railways as a class will be much better than it has been, partly because they have passed the nascent stage and are sounder institutions, anxious to prevent the interruption of their business by fire, and partly because of the insistence of insurance companies upon better construction and practices. The business is heir to some ills, however, for which there is no panacea and seemingly no anaesthetic. Not the least of these is the immense area of the barns made necessary by the number and size of the cars and the exigencies of street railway service. The mutual exposure under a common roof of several valuable buildings on wheels, as it were, making any barn fire a sort of conflagration, is another ill which, however, may be cured by the introduction, as is done on the steam roads in some cases, of steel cars. Another ill for which there is a definite remedy, not heretofore applied, is the poor wiring and heating arrangements of the individual cars, each one of which is more valuable than the average dwelling in which such arrangements would not be tolerated. As an evidence of the importance of this one feature it is a fact, according to the United States Census report of 1902, that 50 per cent. of all the street cars in use were heated and 90 per cent. lighted; of those lighted 90 per cent. and of those heated 63 per cent. used electricity. As the bad car lighting and heating arrangements are practically universal as far as electrical equipment is concerned, it is plain that the conditions are worse than if a number of frame dwellings with poor wiring and heating arrangements exposed one another, since there is always a good chance of confining a fire to one building, whereas the destruction of one housed car nearly always means the loss of all. Unfortunately, we have not regarded car barns as we do conflagration districts, otherwise car builders would long ago have been required to equip their cars electrically and otherwise in accordance with the best accepted practices.

As affecting the chances of litigation and, consequently, the financial obligations under which a road may have to stagger, statistics show that one person is killed per annum at the present time for each 55 cars in use, or one for each 4,000,000 rides taken. The non-fatal accidents are one for each 101,000 rides, these figures including passengers and others injured, say, in collisions, wrecks, run-overs, etc. It is quite evident, therefore, that a company doing a fair business will be more or less involved in suits, and for this reason the acceptance of large lines should be accompanied by an investigation into existing litigation and into circumstances likely to affect future litigation of this sort. Investigation would naturally be made into other matters affecting the moral hazard, especially in the case of new enterprises where disgruntled persons on the right of way, condemnation proceedings and similar forces must not be neglected. It would appear in this connection, for instance, that lines operating in rural districts, while less subject than municipal roads to accidents, in proportion to mileage, number of cars operated and passengers carried, are not freer from suits of various sorts because of the notoriously litigious spirit pervading the bucolic soul.

The Electrification of the New York Central.

A few months ago, upon the occasion of the announcement of the intention of the New York Central & Hudson River Railroad Company to adopt electricity for the Atlantic seaboard end of its system, we took occasion, in commending this progressive plan, to outline the reasons which we assumed were influencing the management, and which had governed the decision of the engineering staff and the consulting engineers. While to the electrical public such a decision, momentous as it is on the part of a great railroad, appears inevitable, there is no doubt that to a great many of the leading steam railroad officials of the country the determination reached seemed more or less hazardous, while even in electrical circles there was agreeable surprise at the fact that the company, instead of restricting electricity to its Manhattan terminals, had resolved to extend the electric zone as far out as Croton and White Plains. In other words, the action of the New York Central Company was presented in somewhat sharp contrast to that of the Pennsylvania Railroad Company, which, instead of going, as well it might apparently, just as far out on the Jersey meadows with its electrical facilities—say 30 or 40 miles—is restricting the use of electricity to a very narrow zone of four or five miles adjacent to the new station, i. e., virtually for the tunnel under the North River alone, inclusive, one might say, of the tunnel to Long Island also.

Whenever Vice-President Wilgus and his consulting staff make public the details of their elaborate study of this problem, either in the columns of the technical press or before some of the technical societies, it will necessarily constitute a most interesting, vital and valuable elucidation of the present status of steam and electricity in the field of locomotion; and it is to be hoped that they may soon feel at liberty to take the engineering profession at large into their confidence. Meantime, however, we believe we do not overstep the bounds in presenting briefly what we gather to have been the reasons for this remarkable extension of the electrical zone by the New York Central, so that for two-score miles out both the suburban and through trains on the system are soon to be handled exclusively by electric locomotives, data in regard to which have already been presented in our columns. So far as we can ascertain, the main considerations upon which Mr. Wilgus and his board had to predicate their noteworthy conclusions were (1) compliance with the law in the region south of the Harlem River—i. e., Manhattan Island—and the probability of other restrictive measures applying as far out as Yonkers and Mount Vernon; (2) the peculiar topography of the region in the vicinity of New York as well as the very high cost of land, both causes pushing the location of the power plant and other facilities to the outer limits of what might be regarded as the suburban region; (3) the desire to secure opportunities for increasing traffic by means of greater speed, smaller units, more frequent service, suppression of smoke, cinders, noise, gas and a more attractive régime in general than would have been found possible so long as steam was adhered to; (4) minimization of annoyances, loss of time, congestion and dangers on account of changing motive power or changing passengers on suburban trains, etc.; (5) development of profitable long haul passenger and freight business due to the inevitable filling up of the whole region north of New York, which, for lack of transportation facilities had been checked in a growth at all comparable with that which has been enjoyed in the suburban regions of New Jersey, such as the Oranges, Englewood, Plainfield, etc.; (6) an underlying reason, probably, that the creation of its own electric service within the suburban area would release the company from the pressure of competition which would unquestionably arise otherwise from competitive rapid transit lines.

It is evident from the most cursory study of these main considerations that once the change to electricity in any extent was agreed upon, the cogency of the arguments in its favor became more and more pressing; and it is creditable to the courage and mental grasp of the men dealing with the problem that they are willing to carry the proposition with all it involves through to the logical and, one might well say, inevitable conclusion. The more one looks into the subject the more evident it becomes that at such points as Croton and North White Plains the best available facilities are now to be had for making the change from steam locomotives to electricity, while the bids and designs submitted as to the electric locomotives remove the earlier operative objections as to the high cost and inability to handle heavy loads at high speeds. It is not only a great thing for the company thus to rid itself of the combined or conjoint electric and steam terminus with consequent double equipment, but it is really a splendid boon for the whole region to be released from the disagreeable features incident to steam traction and to realize at one sweep all the benefits of electric traction in suburban traffic as well as in the through part of the service. In fact, whatever may be the gain connected with the through service, we are very much of the conviction that, foresighted as the staff has shown itself to be, it will be more than agreeably surprised to watch the beneficial results in the upgrowth of new suburban business. The region north of New York is admirably suited for residential purposes, and with the availability of electric facilities, must develop enormously, especialy as all the serious objections entertained toward the old tunnel at the New York end will be abolished. What electricity can do in the general increase of traffic has been shown on Manhattan Island, and the wider area referred to is, after all, a constituent and integral part of the same region, and should indeed have been annexed residentially to New York long ago.

It is from such points of view as these that we believe Mr. Wilgus to have addressed his energies to the problem, and we have no hesitation in avowing a belief that he and his advisors will be more than justified by the results. It has required courage of a high order to undertake such vast changes—without parallel in the domain of transportation—but the public of New York and of the country at large will in a few years have abundant warrant to congratulate itself upon the revolution; while the large capital necessary for such work on this broad plane will not only have recouped itself, but have done much to increase the yield of the older investment. Moreover, it is very encouraging to know that we are not dealing with a project to be carried out at some time or other, but one upon which the necessary work is now being pushed with great energy and vigor.

Storage Battery Plate Construction With Special Reference to High Discharge Characteristics.

By W. W. Donaldson.

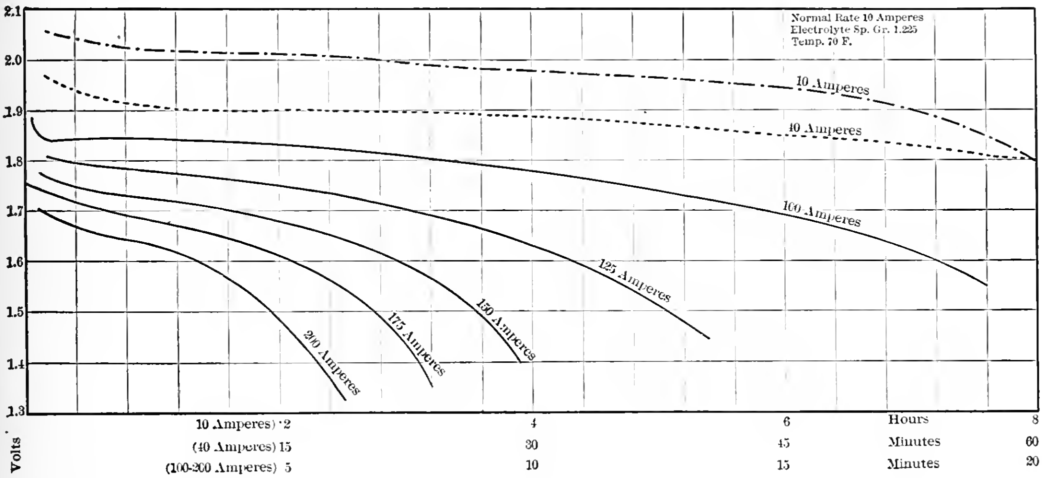
The constantly increasing use and adaptation of electric storage batteries and the proved economy resulting, have had the effect of making electrical engineers look more closely into the features of the plate construction of lead batteries. Although the detailed characteristics are of importance to whatever form of work and conditions batteries are subjected, when high discharge rates are used, the question becomes a much more complicated one than when normal rates are the rule. The largest field in stationary work where abnormal discharges are required is where batteries are used to take the peaks of rapidly fluctuating currents, and these conditions are much more frequently met with in the operation of electric railways. The normal ampere-hour capacity of storage batteries is usually based on a rate which will be maintained for a period of eight hours within an economic voltage range. Such a basis is merely an arbitrary one, as the true practical capacity is when there will be no increase made by further reduction in the discharge rate. This "limit of capacity" is reached much sooner in certain forms of plates than in others, and it is this limitation point which is a direct indication of the superiority of one type of plate over another for watt capacity at high discharge rates.

High discharge rate applications have so multiplied and the storage battery is of so much value for such work that the energies of inventors and of the manufacturers of batteries are being directed toward producing plates in which the "time limit of capacity" is small and inversely, the "rate limit of capacity" is large. At the present time the so-called high discharge rate is four times the normal or eight-hour rate, and the time during which such a rate may be maintained within an economic voltage range, varies from 50 to 70 minutes in different types of plates. If one hour be taken as a mean, then the capacity in ampere-hours is 50 per cent. of the eight-hour capacity. Installations are now made on the hour basis of discharge with allowable "instantaneous" discharges of 50 per cent. additional or six times the normal eight-hour rate. In railway installations where the battery is simply used to take the peaks of short duration, even the full hour capacity is never used. A 20-minute capacity at the same rate of discharge would fulfill all the requirements as far as regulation goes.

Considered as a reserve source of current, the capacity of batteries as installed on their present basis, would be a mere drop in the bucket in supplying current for the operation of a road. In some cases this reserve is found to be of advantage, but in the majority of installations the reduction in first and maintenance cost, if batteries of one-half the present size were used, would much more than compensate for the reserve feature. It must be remembered also that in fluctuating work, the "floating voltage," the point at which the battery stands when neither charging nor discharging, is at the most efficient point when it changes least on charge and discharge, and this is found to be when the battery is three-quarters full. This of course varies with different types, the object being to produce a plate with an efficient floating voltage when it is in as near a charged state as possible. Taking the three-quarter state of charge as the operative condition, the actual effective capacity of batteries for this work is then thirty-seven and one-half per cent. of the eight-hour capacity. Such a state of affairs must conduce to investigation and improvement. Advance in plate construction must result in either increasing the ratio of useful to actual capacity in ampere-hours, or, letting this ratio stand, increasing the discharge rate for shorter periods of time, without shortening the effective life. The discharge curves given below are from a well-known type of plate and show the effective voltage and current capacity for periods of from five minutes to eight hours.

The question arises to what extent and in what ratio will the life be affected by discharging for short periods at these various rates, and whether the greater discharge output than at present used, together with relative decrease first cost and interest charges would more than offset the greater depreciation, should it occur. There should be two types of plates, one designed for two and one hour rates of discharge and with large capacity, and the others for twenty and ten-minute rates, and with relatively small capacity. The latter type of plate is the one which offers the greatest field for the investigator. A plate properly constructed for even moderate rates, should not greatly depreciate when discharged at eight times the normal for short duration peaks, and at twelve times for "instantaneous" peaks. By depreciation is meant not only that the structure of the plate should be preserved, but that the ampere-hour and voltage range should not be lowered. Many plates will, after long use, still be in good condition as far as their structure goes, but will have lost capacity. Structure must be maintained to insure capacity, but properly maintained capacity is bound to be accompanied to a limited extent by a weakening of the structure. The best plate is the one which, towards the end of its useful period, goes to pieces very rapidly and loses its mechanical and electrical efficiency simultaneously. It is the "electrical" characteristics which should have the first consideration in the design. "Provide for good electrical conditions and the mechanical will take care of themselves."

In considering the construction of plates best adapted to high discharge work, the positive and negative must be considered separately. The fundamental requirement for both plates is that their active material must be formed by an electrochemical action. No paste or applied active material should enter into the construction of either plate for stationary high discharge work. Considering the positive or electronegative grid first, this should be "integral": that is, no mechanical or autogenous joints should be present. The plate must not be "built up" of separate parts, nor should the active material be relied on as a conductor of current derived from other but its own reaction: that is, no extraneous current should pass



Discharge Curves.

through it. Time and use always affect such contacts, and loss of capacity follows. No other metal save pure lead should be used, mixtures and alloys always complicating and retarding the proper chemical actions. "Casting" of the basic plate should be avoided, as hard rolled lead gives a density and homogeneity far superior to cast metal.

Of whatever form the plate may be, a "center web" or conductor is necessary for the most even distribution of current, this central conductor in a well-constructed plate never being subjected to the reversals due to charge and discharge unless a very complete discharge at very low rates is used. Rigidity, in excess of that required for proper electrical conditions, need only be provided for in direct ratio to the total weight of the plate. Any allowance beyond this reduces the percentage of effective active support. The "main" conducting and supporting frame, which should never be counted on for any active formation, should not exceed 15 per cent. of the weight of the plate proper, and this, with 10 per cent. in addition (the residue of the "active support") should be all that remains of lead when the plate has lost its useful capacity; that is, a total of 25 per cent. of the original weight of metallic lead. The "basic convertible active lead" should be initially about 85 per cent. of the weight of the plate proper, and all but about 14 per cent. of this should be convertible into the active agent, peroxide of lead. The support area for the active material contact should be not less than 175 sq. in. per pound of plate proper, and should not be greater than 250 sq. in. per pound of support contact; that is, the thickness of this support contact after formation should not be less than 20/1000 of an inch, which allows 10/1000 as a conductor for each layer of active material.

One of the most important, in fact it might almost be said the most important, factor of a plate for such work as we are considering, is that the metallic contact of the active material support with the main conducting frame should be of such a character as not to be impaired or lessened by any action due to subsequent formation of active material. Too much stress cannot be laid on this requirement. As much of the surface of the active material support as possible should be bathed by free electrolyte, and provision be made for vertical capillary diffusion, rather than for horizontal or through-and-through circulation. The active material support surface presented for discharge action should not be less than 33 sq. in. per ampere, for a rate corresponding to eight times the normal. The plate as a whole should be as thin as is consistent and should not exceed one-half inch from face to face. Provision for the retention of the active material must be such that its dislodgement cannot be accomplished by the formation and expulsion of any of the gases incident to the chemical actions or by the change in volume due to its conversion.

Having now covered in a general way the positive support plate, we should consider the active material, peroxide of lead. As it is impossible by the use of applied active material to produce a plate to meet the requirements as to life in high discharge work, this material must be formed electrochemically by some such method as charging continuously at a pressure considerably below two volts, as by the Planté method of charging and discharging and reversing in acid solutions above two volts, or by charging in forming solutions which act directly on the lead itself, producing nitrites, and sulphates and oxides of lead, which are in turn peroxidized by the action of the current. The last method being the cheapest is usually employed.

One requirement for high discharge work is that the active material must be in the form of a very thin layer and should not exceed 8/1000 of an inch in thickness, with a conducting backing 25 per cent. greater or 10/1000 of an inch thick. Such a layer would correspond to .8 of one cubic inch of peroxide per 100 sq. in. of contact support, or (allowing 2.1 ounces per cubic inch) 1.68 ounces per 100 sq. in. This volume of peroxide at a capacity of 2.5 ampere-hours per ounce will give 4.2 ampere-hours per 100 sq. in. at a normal rate of discharge. The weight and capacity per cubic inch of peroxide vary greatly, but these figures are conservative and are easily followed. The ratio of weight of active material to active support should be as 1 to 1.9 (approximately 33⅓ per cent.) and the active material should not be over 18 per cent. of the weight of the plate proper. The porosity, granular and molecular, should be such as to allow the mass of the active material to hold at least its own weight of electrolyte and thus allow for good diffusion of the acid.

Diffusion is necessary for the chemical combinations and consequent production of current, the e.m.f. of the positive plate on discharge being a function of acid concentration. The greater the surface exposed to acid, the better the diffusion, if details of structure are proper. If the peroxide of lead is formed from the basic lead support, it becomes part and parcel of it and the two are knitted firmly together in intimate contact. After time and use this cohesion becomes impaired unless the arrangement of the grid is such as to maintain a constant pressure of the active material against its lead support. If such pressure be maintained and the active material held firmly in place, the tendency for further peroxidization of the support is greatly lessened; and if the formation has been properly carried on, there is a protective coating so dense as to almost stop further action if the original outside layer maintains its proper position relative to the support.

The laws governing the construction of the negative basic plate for high discharge work are the same as for the positive except that there need be no provision made for the formation of active material subsequent to the initial deposit, nor need the current-carrying capacity of the active support be as large. The plate should be integral and of pure lead, alloys causing increased local action with the active material, and local action is one of the chief causes of capacity loss in many forms of negatives. Active contact support should be at least 300 sq. in. per pound of plate proper and grid support 40 per cent. of total weight of plate proper. The support contact should be not less than one-third that of the active material in thickness. The number of square inches of contact support per ampere of discharge should be no less than in the positive, and although the negative plate is, as a whole, of much lower resistance than the positive, a central diaphragm or wet conductor is of value as the principal starting point and distributor of current. One all important necessity of the negative grid is that it should be made in such a way that not more than 10 per cent. of its superficial area be exposed to the electrolyte; less than this amount is even advisable, as the larger the surface of the active material which is bathed by free acid the better will be the maintenance of the negative voltage on high discharge work.

Provision for the retention of the active material forms a chief factor, as dislodgment is very apt to occur by the force of gas accumulation and expulsion, and loss of this kind in the negative cannot be compensated for by further formation as in the positive. This retention of the original volume of negative active material is one of the most difficult things to accomplish. Various, one might say "artificial," methods have been resorted to, but such methods are, as a rule, make-shifts and in the end react badly on acid diffusion and consequently affect voltage. If the proper electrical conditions of the negative plate are adhered to, the mechanical strength will take care of itself. Efficient negative active material, finely divided spongy lead, can be produced by the same methods as explained in connection with positive material. Negatives with applied active material are the most popular and cheapest to prepare, but the "life is not in them" in comparison with those electrochemically formed. The moleculear porosity of spongy lead should be such that it contains at least twice its volume of acid, although this ratio can be increased if the design of the plate should warrant it. Spongy lead does not thrive in strong acid, so every provision possible must be made for acid diffusion and renewal in the pores.

The volume of material should not exceed one cubic inch to each 100 sq. in. of support contact, and the capacity should not be less at normal rates than 4 amp.-hours per cubic inch. In a correctly designed plate this should give 15 amp.-hours per pound of plate proper. Such should be the initial capacity of the negative, but only 60 per cent. of this should be used; that is, the capacity of the positive should be 60 per cent. of the negative, so that the capacity output is limited by the positive, as working negatives down to low voltages is very deleterious, increasing largely local action. There is another reason for having a surplus increased capacity in the negative, which is that as time goes on, there is a shrinkage and molecular change, the former causing a loss of mechanical and electrical connection of the active material with the support, which, together with the molecular change, causes loss in capacity. If the active material be formed from the lead plate itself, it is part and parcel of it and is in continual intimate contact, so that any loss in capacity which occurs should be charged to the molecular change. When from either of these two causes or from both, too great a capacity loss occurs, the plate should be capable of complete reversal and reformation without injury or loss of active material. The life of the negative plate is generally held to be twice that of the positive (what is meant by "life" being rather an unknown quantity); but there is no reason why this ratio should not be more than doubled if strict and scientific principles are adhered to in the construction.

As I stated at first, electrical engineers and those directly interested in the use of storage batteries would find their time well repaid if they searched for strong and weak points in plates which they contemplated buying, with the same ardor they expended on the other parts of electrical equipments.

Annual Meeting of the American Institute of Electrical Engineers.

The annual meeting of the Institute was held in New York City at the Chemists' Club on May 17 and 18. In view of the fact that the Institute will take so prominent a part in connection with the Electrical Congress at St. Louis in September, the directors did not lay out a very extensive programme. This would explain the small attendance of members—the number at no time exceeding 150.

On Tuesday morning, May 17, papers were presented to Mr. W. L. Waters on the "Predetermination of Sparking in Direct-Current Machinery"; by Mr. E. H. Anderson on the "Effect of Self-Induction on Railway Motors," and by Dr. W. E. Winship on the "Calculation of Line Batteries." The reading of these and the discussion which followed lasted until 1.30 P.M., when lunch was served. There was no regular meeting in the afternoon, but on the invitation of the Interborough Company the members visited in a body the Rapid Transit Subway, entering at Columbus Circle and Fifty-ninth Street and walking down the track to Fiftieth Street, from which point a visit was made to the sub-station at Fifty-third Street. Members were received by Messrs. L. B. Stillwell and H. G. Stott, who explained many features of the work. The subway was found in a well advanced condition, but doubts were expressed whether it could be ready before late fall, especially as all the rolling stock has to be got into operation.

At the evening meeting the result of the annual election was declared, on the report of the tellers. The successful candidates were as follows: President, Mr. John W. Lieb, Jr.; vice-presidents, Prof. W. E. Goldsborough, J. J. Carty, Col. S. Reber; managers, Messrs. H. G. Stott, L. A. Ferguson, J. G. White and Dr. S. S. Wheeler; secretary, Mr. Ralph W. Pope; treasurer, Mr. G. A. Hamilton. The report of the board of directors was then read, showing that the growth of membership had been maintained. The total May 1, 1903, was 2,229, and the net total of membership April 30, 1904, was 3,027. The ordinary receipts of the Institute during the year had reached the substintial sum of $40,986, and a balance was shown of $4,592. After making various allowances and deductions to funds, the net balance in cash or its equivalent of $12,337 was shown to be immediately available for any ordinary or unusual expense of the Institute. The balance sheet showed the finance committee to have done excellent work and the Institute to be in thoroughly sound and prosperous condition. The inventory value of the library, as shown in the report of the library committee, was increased to $21,737, the former valuation having been based upon a nominal valuation for insurance. A sum of $3,118.75 was expended upon the library during the year. With regard to the local organizations, in respect to which Mr. C. F. Scott made a further separate report during the evening, it was shown that there are at present twenty-nine Institute branches, fifteen of which are in cities and fourteen students' meetings in technical schools. The aggregate attendance at such meetings is 1,250, about 400 being students. With respect to the Electrical Congress, the details already given out were repeated, and it was stated that at the time of the report the Congress subscribers numbered about 1,600, while 157 papers had been promised from leaders in the profession. It was also stated with regard to the adoption of a standard cell that this matter will be submitted to the International Electrical Congress, and that the cadmium cell of Mr. Weston is proposed as a universally recognized standard. Details were also given as to the Union Engineering Building, and condition of the project; and supplementing the statement in the report, Mr. Calvin Rice, chairman of the building committee, was able to state that already $47,200 had been pledged and that the work of the committee was being actively pushed.

As an instance of the *esprit de corps* existing in the Institute, it was stated that Boston had pledged its best efforts, while the local section in Iowa had already sent in the generous subscription of $600. It may be added that on Wednesday Mr. Arnold, at the morning session, announced amid considerable applause that Mr. Edison had just given $5,000 to the fund, bringing it well above the $50,000 mark. Since then, a subscription from Dr. M. I. Pupin of $5,000 has been announced, and before the meeting closed the fund was above $60,000.

With regard to meetings, it was stated that the annual convention at Niagara Falls in 1903 had brought out an attendance of nearly 500 members and guests. It was also stated that preparations were being made for a special meeting at Chicago on June 21 and 22 to be devoted exclusively to transmission subjects.

A paper was presented during the evening by Mr. B. G. Lamme on data and tests on 10,000-cycle per second alternators.

The session on Wednesday morning was followed by luncheon, and the afternoon was spent in a visit to the library and technical laboratory of the Columbia University under the guidance of Profs. F. B. Crocker and George F. Sever.

Mr. John William Lieb, Jr., the new president, was born in Newark, N. J., February 12, 1860, he attended the Newark Academy and the Stevens High School, Hoboken, N. J., and graduated from the Stevens Institute of Technology in 1880 with the degree of mechanical engineer. In 1880 he engaged as draughtsman with the Brush Electric Company in Cleveland. He entered the employ of the Edison Electric Light Company, New York, in 1881, as draughtsman, and was transferred to the experimental department at the Edison machine works in 1882. He assisted in the tests of the first "Jumbo" direct-connected Edison dynamo, and by Mr. Edison was put in charge of the installation of the electrical equipment of the old Pearl Street Edison station, under the direction of Mr. C. L. Clarke, chief engineer. He also assisted in the tests and experiments incident to the starting up of that pioneer station, the first commercial station in the United States supplying current for incandescent lighting and power from an underground system. On the inauguration of regular service, September 4, 1882, under the auspices of the Edison Electric Illuminating Company of New York, Mr. Lieb was appointed its first electrician.

J. W. LIEB, JR., PRESIDENT-ELECT, A. I. E. E.

A syndicate of Italian capitalists with Prof. Colombo as technical adviser, having purchased a complete equipment of boilers, engines, dynamos and Edison underground system for Milan, Italy, Mr. Lieb was selected and dispatched by Mr. Edison to direct the installation. The Milan station, equipped with Babcock & Wilcox boilers—six 150-hp Armington & Sims engines and Edison "Jumbo" dynamos, began regular service in 1883 and Mr. Lieb remained in charge as manager on the organization of the Italian Edison Company. He was appointed in turn its chief electrician, director of stations and chief engineer in general charge of the technical department of the company, engaged in manufacturing electrical apparatus, installing isolated plants and constructing and operating lighting and power stations throughout Italy. Mr. Lieb's company was among the very first to exploit the alternating-current system, beginning with a plant in Milan, Italy, in 1886, and using also the Thomson-Houston arc system extensively. His last work in Italy was in the electric railway field in connection with the installation of the trolley system in the city of Milan.

Being offered an appointment with his old company—the Edison Electric Illuminating Company of New York—Mr. Lieb returned home in 1894, at first in the capacity of assistant to the first vice-president and advancing by steps to third vice-president and general manager. On the consolidation of various lighting interests in New York City, under the corporate name of the New York Edison Company, he was appointed third vice-president and associate general manager, which position he now holds. He is also president of the Lamp Testing Bureau and director in several electrical corporations.

Mr. Lieb is a vice-president of the American Institute of Electrical Engineers, member of council of the American Society of Mechanical Engineers, member of the American Society of Civil Engineers, past president of the Association of Edison Illuminating Companies, past president of the New York Electrical Society, second vice-president of the National Electric Light Association, member of the Associazione Elettrotecnica Italiano, Franklin Institute, American Academy of Political Science and the Engineers' Club of New York City. He is also chairman of the general reception committee of the Institute for the International Electrical Congress.

Below are brief abstracts of the several papers. An abstract of the discussion will be given in the following issue.

Mr. W. L. Waters read a paper on "Predetermination of Sparking in Direct-Current Machines," in which he pointed out the insufficiency of a theory of commutation based on reactance voltage without accounting for other factors entering, and showed that the design of a direct-currentd machine with respect to sparking is a compromise between a number of conflicting conditions. A formula is developed in the paper which is stated to include all the important factors affecting sparking; and while empirical, it has been gradually built up as the result of experience, different terms having been added from time to time to take different conditions into account. It does not, however, take into account all the conditions that affect sparking, and one is cautioned that it must be used with considerable discretion.

"Effect of Self-Induction on Railway Motor Commutation" was the title of a paper read by Mr. E. H. Anderson, the subject matter being based upon a study of oscillograph records, of which 13 are photographically reproduced in the paper. The fundamental causes of sparking are stated to be, first, the interruption of the line current flowing through the conductors connected to two adjacent commutator bars; and, second, the interruption of a local current produced by a voltage generated in the conductors connected to the commutator bars which lie under the brushes, this voltage being due to the shifting of the field caused by the armature magnetizing effect, and is influenced somewhat by the voltage per bar of the motor. The voltage from this latter cause is additive to the first mentioned or reactance voltage of commutator based upon line current. The local current should be cut down as much as possible, and consequently railway motors have, as a rule, low armature turns and very high flux and field turns compared with those used in the direct-current generator. Since in large motors the local copper circuit is of low reactance as compared with the brush contact, nearly all the energy of the local current is delivered as heat on the commutator. Should the motor be very large, the stability of the field relatively to the armature must be great in order to limit the local current to a low value, as otherwise the motor will spark and glow at the brushes. On the other hand, in small machines the resistance of the local copper circuit may be high compared to the carbon contact resistance.

Stability of flux is quite essential to good commutation, and this may be secured by the usual method of great saturation or by compensating for the distributing element by means of armature reaction. The latter method points to a motor with distributed winding of the field, pole pieces of great pitch, equal density over the pole face and relatively few turns.

The paper refers to experiments with large direct-current motors, which motors have a tendency to flash when running at free speeds and light currents, the current being interrupted and contact restored again with full pressure across the motors. It is found that motors with exceedingly good commutation at normal loads or on overloads at rated pressure, and even motors which commutate without flashing over with full load current at double-load voltage, have a peculiar tendency to flash over when the current is changed rapidly or the circuit interrupted and made again with full pressure on the motors. Two causes are given for this, one a transformer pressure induced in the armature coils lying under the brushes owing to the rapid change of current, thereby causing large local currents to flow in the coils and through the brush contact. On interrupting this current as the coil passes from under the brush, there is a flash between bars and the line current will follow this local brush from bar to bar. The predominating cause, however, is the slowness of the main flux to respond to excitation, thereby allowing a great rush of current. The paper gives in detail a number of tests made in the study of this phenomenon, but no remedy for its ill effects is offered..

The papers of Messrs. Waters and Anderson were discussed at length by Messrs. E. R. Douglas and Thorburn Reid, both of whom entered with much detail into the various phenomena of commutation, their cause and the manner in which their effects may be met.

Mr. W. E. Winship presented a paper entitled "The Calculation of Line Batteries," in which formulas are deduced for the calculation of storage batteries for use in electric railway work, and with particular reference to "floating" batteries. It is stated that the capacity of a battery should be reckoned approximately at the rate corresponding to the duration of all the net discharges and not at the rates at which the separate discharges occur. This follows from the reason that if a battery is discharged at a high rate for a short time and then is allowed to recover, and the same cycle is repeated a number of times, the ampere-hour capacity of the battery very nearly approximates the capacity at the rate corresponding to the total time elapsing.

In addition to the method of calculation presented, it is stated that comparative calculations should also be made considering, first, the cost of copper alone, and the cost of copper and batteries for equivalent line voltages; also the cost and depreciation in the two cases together with the transmission losses. The battery should be credited with the influence which the load equalization affected would have on the cost of power production; and the emergency value of the battery in case of temporary break-down should receive consideration. With fairly long lines, the ends of which are 6 to 10 or 12 miles distant from the power house, and the cars running are relatively few in number and heavy, a battery installation will generally cost less than equivalent copper. If there are grades and the cars stop and start at a distance from the power house, the value of the battery as a load equalizer will nearly always justify its installation.

Mr. B. G. Lamme presented a paper entitled "Data and Tests of a 10,000-cycle-per-second Alternator," which describes the construction and test of a 2-kw, 150-volt, 10,000-cycle alternator designed and constructed at the Westinghouse works for M. Maurice Leblanc for use in certain special telephone work.

Mr. H. H. Barnes presented a paper entitled "Notes on Fly Wheels," in which he considered the subject from the standpoint of electrical generation. A formula is given for the calculation of a fly-wheel, taking into consideration the avoidance of resonance. The main conclusions are that the fly-wheel, as distinct from the assistance given either by the engine governor or the damping of the unit, is impotent to insure satisfactorily synchronous operation. Except for these two influences the tendency toward accumulative surging existing in the unit would predominate and parallel running would be impossible. A somewhat lighter fly-wheel is advisable than would be considered conservative in practice to-day. Electromechanical resonance is a serious danger that must be avoided by making a proper choice of fly-wheel, which should at the same time be satisfactory for general operating purposes.

Prof. W. S. Franklin read a paper entitled "The Single-Phase Induction Motor," in which is discussed the various factors entering into design, and formulas deduced for the calculation of such a motor.

Mr. George H. Rowe, in a paper entitled "Wave Form Variations of a Long-Distance Line," gave an account of a study of the lines of the Standard Electric Company, California, made by means of the oscillograph. The paper contains a number of reproductions of records taken with the oscillograph, which is stated to offer the best means of studying variations in wave form, amplitude factor, surgings, pumping, etc. The best form for this work is the moving film or falling-plate type, without a synchronous motor attachment; and it should be insulated for use in high pressures and fitted with non-inductive metallic resistances. Among the conclusions of the paper are that it is advisable to substitute induction motors for synchronous motors on lines with large charging current, the latter being used as synchronous compensators properly distributed. It is impossible to design machines to satisfy all wave forms, and the variation in amplitude factor in a long line must be considered. The core loss variation should also be considered, and the charging current may differ from that calculated on the assumption of a sine law. Assumption of sine wave form on long lines and applied to insulator and insulation testing may lead to error. The variation of wave form is partly due to the distorting effects of the hysteresis loop under different conditions of load.

The Nernst Lamp.

IN 1897 Prof. Walther Nernst, of the University of Göttengen, filed his first patent application on the principles of the lamp which bears his name, and concurrently rumors concerning the new lamp began to appear in the technical press. It was not, however, until the spring of 1899 that the issue of the first of a series of patents disclosed to the public the main features of the invention, and not until two years later that the detail patents appeared. Almost a year before the issue of the first patent, however, the distinguished German professor on a visit to this country brought his invention to the attention of Mr. George Westinghouse, with the result that the American rights were disposed of; and with characteristic promptitude Mr. Westinghouse at once gathered a technical staff for the development of the new light to the commercial stage.

What has been accomplished by this staff is strikingly illustrated by a comparison of the Nernst lamp of to-day with that illustrated in the early patents. Such a comparison does not, however, involve any reflection on the inventor; as compared, for example, with the problems presented in the development of the incandescent lamp, the difficulties to be overcome in reaching the commercial stage with the Nernst lamp were enormous. In addition to the difficulties of purifying and treating in commercial quantities the component rare earths of the glowers, were problems relating to regulation, preliminary heating and automatic circuit control, and those of another order none the less simple relating to glower terminal connections, and to the numerous constructional details which each step presented for solution. Nevertheless, in but little over a year from the commencement of development in this country, Nernst lamps were in experimental use on commercial circuits, and subsequent work has been largely in the direction of refinement in processes and perfection of mechanical details.

No account of the genesis of the Nernst lamp would be complete without reference to the brilliant and self-absorbing work of the staff to which Mr. Westinghouse confided the task of its commercial development. A partial record of the work of some of these gentlemen is contained in a long list of patents, which are evidence of the masterly manner in which the scores of problems presented were given solution. Where all have given devoted service in a cause, it is embarrassing to discriminate, but none concerned will, I believe, begrudge a major share of credit to Messrs. Alexander J. Wurts, Henry Noel Potter, Marshall W. Hanks, Max von Recklinghausen, Murray C. Beebe and Edward Bennett.

That the Nernst lamp is now a fixed factor in the lighting field appears beyond dispute; and although it has been handicapped as to rate of progress by a conservatism in the central station field in vivid contrast to conditions of ten or more years ago—when merely to be new was a qualification inspiring a fervid welcome—the glower lamp in its present state calls for serious attention on the part of all central station men. In what follows some account, gathered during a recent visit to the Nernst lamp factory, at Pittsburg, will be given of the processes of manufacture of the Nernst lamp, together with a consideration of some of its features of special importance from the operating standpoint.

In view of the little-known nature of the constituents which compose the glower of the Nernst lamp—commonly known as the rare earths and of which the more recently discovered member, radium, has acquired the widest fame—their impurity in native state and the previous almost entire lack of knowledge concerning their treatment in any form, an immense amount of work has doubtless been necessary in arriving at the technical information now in the possession of the manufacturers. The list of rare earths is a long one —numbering almost two score—and it can be imagined that no small labor was involved in testing various combinations thereof, selecting the ones most suitable and determining the best proportions in the combination for a glower. Naturally information of this character is not given publicity, and consequently so far as relates the raw material and its treatment, we are limited in our statements to disclosures in the several Nernst patents.

In one of the earlier Nernst patents it is stated that the mixture which has in high degree the requirements for a glower consists of about 80 parts of oxide of zirconium, 10 parts of oxide of erbium and 10 parts of oxide of yttrium. These are taken in a powdered state, thoroughly mixed, and a paste then formed by adding water and a binding material such as tragacanth or dextrine. In later patents it is stated that very excellent results have been obtained with a mixture of approximately 70 per cent. of oxide of zirconium and 30 per cent. of oxide of yttrium. Other mixtures which are stated to have been used with good advantage are as follows: 10 per cent. of oxide of zirconium, 70 per cent. of oxide of thorium and 20 per cent. of oxide of yttrium; 70 per cent. of oxide of thorium and 30 per cent. of oxide of yttrium; 0.5 per cent. of oxide of cerium, 80 per cent. of oxide of thorium and 19.5 per cent of oxide of yttrium. These percentages, it is stated, may be widely varied, and generally speaking, the oxides of the rare earths are well adapted for use in mixtures in widely varying proportions. The patents also refer to oxide of magnesium as a suitable component.

Describing in the later patents the preparation of the material of the glowers, it is stated that the oxides to be used are thoroughly pulverized and intimately mixed, and a plastic mass then made by the use of a binder of clear starch. The water used in making the paste should preferably be distilled to avoid the presence of lime, which, being more volatile than the oxides of the rare earths, its presence is undesirable. In another connection it is stated that certain of the rare earths are inapplicable for the same reason. The plastic mass is then inserted in a press and forced through a small hole of requisite diameter, this process being the same as used in "squirting" incandescent lamp filaments. The rods or threads thus produced are then allowed to dry, when they acquire sufficient strength to be conveniently handled. It is stated to be desirable that the greatest specific gravity possible shall be given to the material. In the next process, that of heating, it is stated to be desirable for the heat to be gradually applied, but eventually carried to an extremely high degree. Upon cooling, the rods are ready to receive terminal connections.

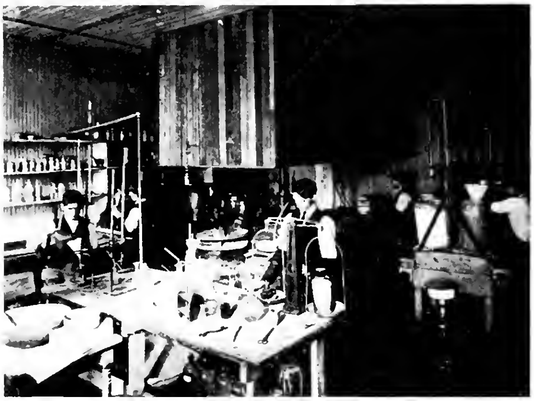


FIG. I.—A ROOM IN THE CHEMICAL DEPARTMENT.

As previously stated, the processes at present employed in treating the rare earths in their passage from the mineral form in which they are found to the state of glowers, are not given publicity. In general it can be said, however, that the processes involve chemical skill of the most expert kind, and close attention to the minutest detail. In particular, it is extremely necessary that all the chemicals employed as reagents or otherwise shall be absolutely pure. For satisfactory results, the degree of heat applied during the treating process must be exactly controlled, and also the concentration of precipitating solutions.

Though organized for work on a large scale, a walk through the factory laboratory creates the impression that one is being shown the workshop of a splendidly equipped investigator into the minutae of chemistry, instead of a department of a lamp works. One requirement in the processes is absolute cleanliness, and to assist in assuring this, that portion entering the laboratory of the grimy ambient which in Pittsburg passes for atmosphere, undergoes thorough filtration. The refinement of care with respect to the material does not cease, however, in the chemical laboratory proper. Each time that new material is prepared a portion is made into test glowers, which are then mounted as if in lamps, and a careful record of performance kept. The admirable organization of the Nernst works is very well shown in the elaborate records kept of glower material from its crude to final state. By means of this system every step from the crude material to the finished product is a matter of record, and as a consequence any abnormality can at once be traced to its source. The net result of this system of records and stage tests is to give complete assurance that when once mounted in a lamp, each glower will give the exact performance for which it was destined. In fact, throughout the factory one is everywhere

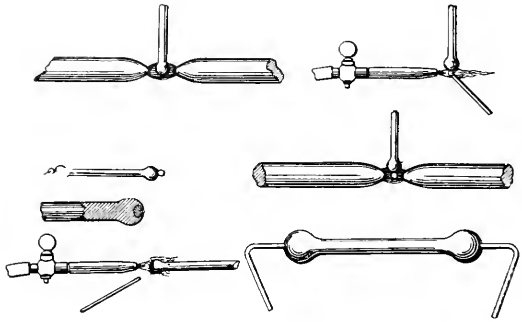

FIG. 2.—PROCESS OF MAKING TERMINALS.

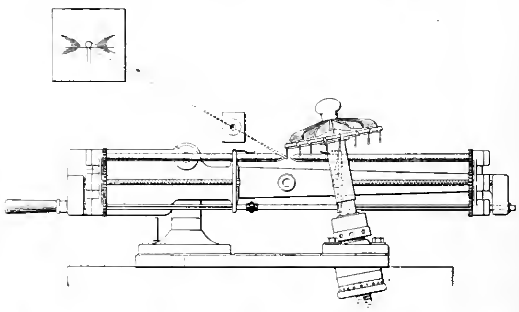
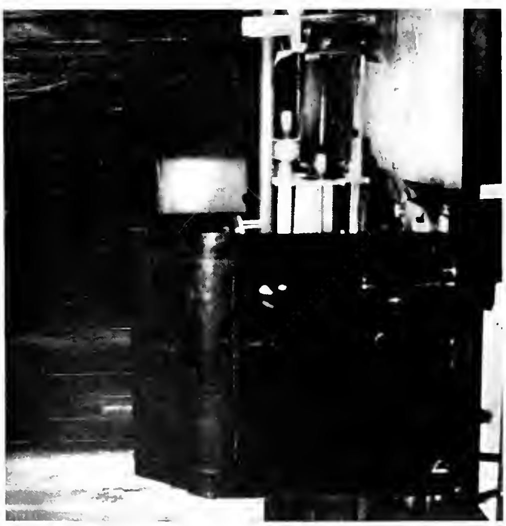
impressed at the extreme care bestowed on that part of its organization which relates to securing exact uniformity of product.

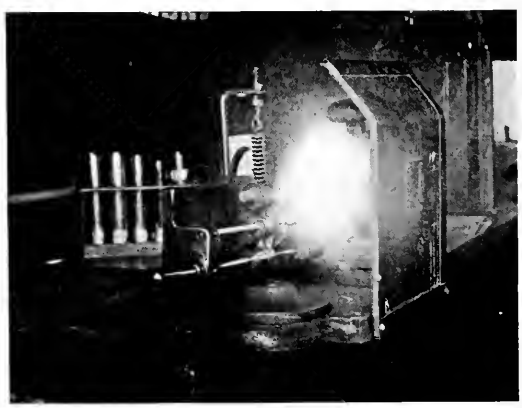
Previous to the description of the process of mounting glowers, some data may here be given as to their dimensions. At normal temperatures practically non-conductors of electric current, when heated the Nernst glower possesses most of the properties of ordinary conductors. An exception is with respect to the method of conduction, but as the electrolytic theory on this point has no bearing on what follows, it may be here ignored. To adapt to different voltages and currents, the cross section and length of the glower is consequently varied as in the case of the incandescent lamp filament. The single filament of a 25-cp., 110-volt lamp has a diameter of .025 in., and a length over all of .62 in., the corresponding dimensions for a 30-cp., 220-volt lamp being .014 in., and 1 in. In the three glower, 200-cp., 220-volt lamp these dimensions become .025 in. and 1.18 in., respectively, and .025 in. and 1.18 in. in the six-glower 500-cp., 220-volt lamp. The glowers, while perhaps intrinsically more fragile than the carbon filament, are, owing to their much greater cross section, quite sturdy when mounted and not subject to breakage in ordinary handling.

Perhaps the most troublesome problem presented in the development of the Nernst lamp was in connection with the glower terminals. The final solution as found by Mr. Marshall W. Hanks, consisted of embedding a platinum bead in the end of the glower and fusing to this a platinum terminal wire. Thus the trouble previously met through contraction in the material of the ends, turned to a positive benefit, in that the terminal is thereby more securely held. The rods of glower material are cut to a length somewhat longer than that of two finished glowers. Each end is then heated in turn in an electric arc, and as the material softens the end assumes a spherical shape. Then in an oxyhydrogen flame a platinum wire is plunged for a short distance into the heated globule, when a small portion becomes separated at a point where the wire has been previously nicked, after which the end is again placed in the arc for an instant. To the platinum globule thus embedded in the spherical end is then fused the terminal wire with the aid of an oxyhydrogen flame. The several stages of this operation are illustrated in Fig. 2, but with reference only to a single glower. Finally, the end of the terminal wire is fastened to an aluminum plug which facilitates connection of the glower to the lamp holder.

The most interesting part of this process is, however, that which relates to the manner whereby the second terminal connection of a glower is made. For satisfactory results it is, of course, necessary that the completed glowers of a given rating should be uniform as to resistance, and by means of a beautiful arrangement due to Mr. Marshall W. Hanks, this is as exactly as possible accomplished. Referring to Figs. 3, 4 and 5, it will be seen that a number of glowers are mounted on a revolving stand and the lower ends in turn brought under the influence of an arc between two carbons. A magnified image of the glower and the arc is thrown on a screen in front of the operator, and also the image of a gauge line. As witnessed in







FIGS. 3, 4 AND 5.—APPARATUS FOR MAKING GLOWER TERMINALS.

actual operation, as soon as the glower treminal comes within the influence of the arc, it is seen to swell and gradually but rapidly an almost perfectly spherical globule forms on the end; as this latter increases in size it approaches the gauge line, and when it becomes tangent with it, the operator revolves the table, the motion withdrawing the glower under operation and introducing another. In a subsequent operation the platinum bead is introduced as above described, and the platinum leading wire fused to this. The entire operation requires but a very short time, an experienced operator being able to turn out 350 glower beads per hour.

While great accuracy is possible in determining the length of the glowers by the above method, it is, of course, not possible in commercial production to prevent some variation in the voltage value of the glowers. The latter therefore have to be sorted before consignment to stock, which operation consists in the measurement of voltage while normal current passes through the glower. Naturally the proper voltage value in this test will be somewhat higher than the corresponding value in the lamp, due to the mutual heating effect of the different glowers in the case of multiple glower lamps, and to the temperature existing within the enclosing globe. In marking the standard packages, containing 10 glowers each, with the voltage of the lamp for which they are suited, it is therefore obvious that allowance must be made for this difference, in addition to 11 per cent. drop in ballast and cutout.

A very neat and original device is used for glower sorting as shown in Fig. 6, having the form of a wheel, the periphery of which carries a number of special mountings for making glower connections in a speedy and positive manner. The wheel is rotated on its axis, commutating connections being made between the glowers and supply circuit. All of the operations, including taking current and voltage measurements, are done by a single operator, the output of each operator being about 1,300 glowers per day.

Before passing to further details of manufacture, a summary may here be given of the organization of the several parts of the Nernst

FIG. 6.—TESTING GLOWERS.

lamp. As has been previously stated, a Nernst glower at normal temperatures is practically a non-conductor of electric current, and consequently to put a lamp in operation it is necessary first to heat the glower to a certain temperature. This is accomplished by means of a heater, which will be described later in detail. When a lamp circuit is closed, the current from the line first passes through the heater circuit, which circuit is automatically cut out when the glower becomes sufficiently conductive. Referring to Fig. 7, it will be seen that, assuming the glower to be non-conductive, all of the current will first pass through the heater. As the glower becomes conductive a current begins to flow through its circuit, this circuit also including an iron "ballast" or resistance wire, which will be referred to later, and a cut-out coil; when the current reaches a predetermined amount, the cut-out coil operates and the heater is cut out of circuit. Thenceforth the current passes through the glower, ballast and cut-out coil, to line. In Fig. 8 the organization of the several parts in an actual lamp is shown.

This brings us to the consideration of the second very interesting feature of the Nernst lamp—the ballast coil, due to Mr. Henry Noel Potter. As in the case of ordinary conductors, the resistance of a glower when heated varies with its temperature, and it happens that at the temperature most desirable in the working of the glower, the decrease of resistance with increase of current is quite rapid. As a consequence, without any controlling device in circuit, at this particular point a relatively small increase of current might so reduce the resistance as to quickly result in a flow sufficient to burn out the glower. Iron wire possesses the opposite property of increasing in resistance as the temperature increases, and it very fortunately happens that at a certain critical temperature this increase of resistance becomes very considerable for relatively small increases of temperature. If then an iron wire is placed in the circuit

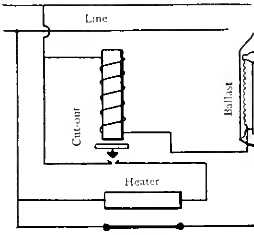


FIG. 7.—NERNST LAMP CIRCUIT.

of the glower, of a size selected so that its temperature during the normal working of the lamp is at or near the critical point, an increase of current will cause its resistance to increase in about the same proportion as that of the glower decreases. This is illustrated in Fig. 9, which gives curves of the variation of resistance with increase of temperature of a glower, and ballast, respectively (the latter to a larger scale), and a resultant curve which represents the variation of the current passing through the lamp with increase or decrease of voltage. The flatness of the glower curve indicates that a very slight change of voltage would produce a very great change in the current, while the effect of the ballast wire is to make the resultant curve almost vertical in its working part; thus a very considerable change in voltage will necessarily give rise to but a small change in current.

As constructed, the ballast is kept within remarkably small compass, the dimensions of a tube for a three-glower lamp, for example, being 11-16 in. in diameter and 2 3-16 in. long. The diameter of the wire varies from .001 in. in the smallest ballast to .004 in. in the largest. The length of the wire before being given a helical twist, is from 4 in. to 12 in. and the resistance from 25 to 80 ohms. The drop in the ballast is about 10 per cent. of the total drop between the lamp terminals. The wire is supported on a nickel standard having a cross arm to support the wire, which is threaded through porcelain insulators fused on the standard with glass. The bulb is finally exhausted and then refilled to about atmospheric pressure with hydrogen obtained electrolytically from an alkali solution.

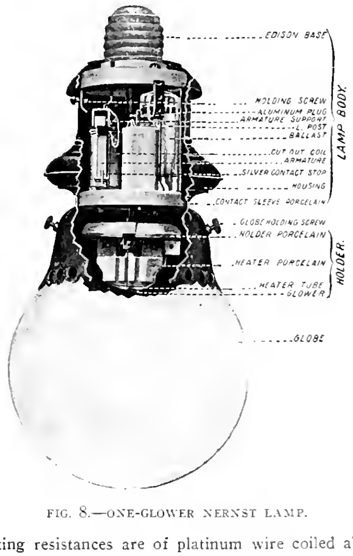

FIG. 8.—ONE-GLOWER NERNST LAMP.

The heating resistances are of platinum wire coiled about porcelain, then covered with a porcelain paste having the same coefficient of expanison as the wire, and baked. Owing to the necessity of having the porcelain uniform in quality and properties, the raw materials are worked into the finished product at the factory—not only for the heating resistances but also for the mountings in the lamp frame. In the case of the smallest lamp, after baking the covering cement, the rod carrying the resistance is heated to a red glow and wound on a mandrel to a spiral form, the heat being applied as the winding proceeds. Naturally this is a delicate operation, but the arrangement for the purpose has been so carefully worked out that the operation is carried on by boys.

A problem of no small magnitude was involved in realizing a cut-out absolutely reliable in its action yet miniature in size, capable of controlling a current rising to several amperes in value and of remaining continuously in circuit with the lighting current. As perfected the cut-out, which breaks the circuit at two points, weighs for a three-glower lamp but 3¼ ounces and occupies a space of 2 3/16 in. x 1⅞ in. x 13/16 in. The contacts are of silver. The cut-out coil after winding is impregnated with a mineral compound which allows the insulation to stand a red heat if necessary, and is finally covered with asbestos sheet. The drop in the coil is about 1 per cent. of the total drop between lamp terminals. The number of turns in a coil are so fixed that the heater circuit is cut in when four glowers of a six-glower lamp are burned out, or two glowers of a three-glower lamp, or one glower of a two-glower lamp. Fig.

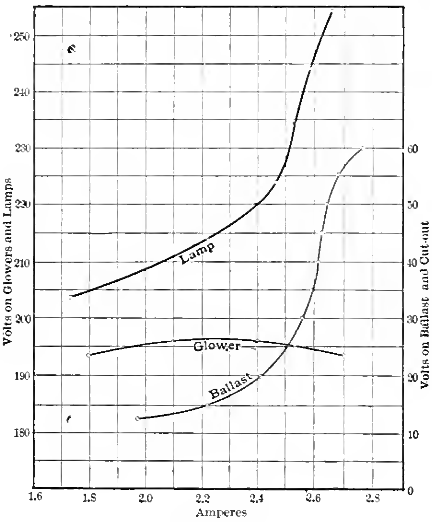

FIG. 9.—NERNST LAMP CURVES.

11 shows in outline a cut-out. As will be seen, the construction is very simple, the contact being maintained through the action of gravity; when the contact is broken the armature moves into a position with respect to the magnet poles which ensures a strong magnetic lock.

Entering a field that in late years has become strangely conservative, the Nernst light encountered as a late-comer conditions that its rivals in possession had escaped in the earlier days. Moreover, these latter have presented a solid front to what appears to have been regarded as an interloper, and every claim made for the Nernst lamp has been vigorously contested. As is apt to be the case in commercial competition, nothing meritorious has been conceded to the rival, and every statement in its favor met by a counter-statement showing instead a deficiency. What follows involves some of the controverted points, which are here presented in the light of the most reliable information which has been found available.

EFFICIENCY OF THE NERNST LAMP.

When we come to the subject of the economy of the Nernst lamp quite an array of diverse opinion is presented. Drude, the distinguished German physicist, credits the Nernst glower with an absolute luminous efficiency of 12 per cent., the corresponding efficiency of the incandescent lamp filament being variously stated by authorities at from 2.5 per cent. to 6.5 per cent.; on the other hand, the claim has been made by an incandescent lamp interest that the efficiency of the Nernst lamp in commercial service is practically the same as that of the ordinary incandescent lamp. If, however, we accept Tumlirz's constant of 5.2 for the number of candles per watt for a luminous efficiency of 100 per cent., a 3.1-watt incandescent lamp has a luminous efficienty of 6.5 per cent. and a Nernst glower of 12 per cent. luminous efficiency corresponds to a consumption of 1.62 watts per cp.

When one refers to the candle power experiments that have been

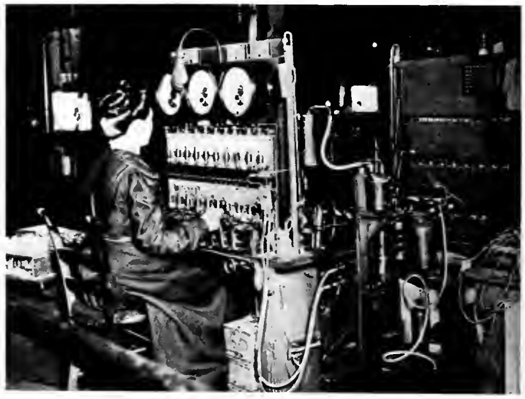

FIG. 10.—TESTING BALLASTS.

made on the commercial Nernst lamp, the results are apt to be so contingent on the experimenter's interpretation of what constitutes a candle power—whether it is to be considered in a spherical, hemispherical or some other significance—that the data are of little value for comparative purposes. It happens, however, that the Photometric Committee of the National Electrical Light Association has reported on measurements of the Nernst lamp in such a form that a comparison can be made between the performance of this lamp and that of arc lamps tested by the same committee and presumably according to the same methods. According to this report, the watts per hemispherical candle power consumed by a six-glower lamp were 1.88 per cp. with clear globe as compared with the following enclosed arcs with opal inner globes and clear outer globes: Direct-current series, 1.3 watts; direct-current multiple, 2.25 watts; alternating-current series, 1.19 watts; alternating-current multiple, 2.53 watts. With an opaque globe the consumption of the Nernst lamp was found to be 2.10 watts per cp.

Since the competition is with the multiple arc lamp, and since for interior lighting, hemispherical candle power can be accepted as a proper criterion, it will be seen that according to these tests the Nerst six-glower lamp is notably more efficient on the above basis than either the direct-current or alternating-current type of multiple

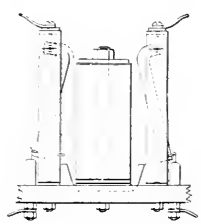

FIG. 11.—NERNST LAMP CUT-OUT.

enclosed arc lamp; and on the basis of either of the figures above given, it is still more notably efficient than the most efficient type of incandescent lamp used on commercial circuits, namely, the 3.1-watt lamp.

The lack of agreement as to what shall constitute a measure for practical illuminants is becoming daily more unsatisfactory and as a practical problem is pressing for solution—not only on account of the occasion which the present condition offers for all manner of claims and counterclaims on the part of those interested commercially in illuminants, but also because the public has a right to, and should be given in this as it has in other branches of business, some definite standard within its means of comprehension by which to gauge what it purchases. And since the user of electric lighting current only wants that commodity—if we dare to term it such—for the illumination which it produces, the measurement of illumination where it is actually needed is what, in this connection, appears to be the desideratum. This is the view of the Nernst Lamp Company, and Mr. Alexander J. Wurts, chief engineer of the company, has proposed the following method of comparing the effect of illuminating powers of artificial sources of light:

The arrangement to comprise two rooms standardized with reference to size, color and furnishings, some convenient point of view being provided from which the illumination of both rooms may be readily compared. The primary room to be illuminated with incandescent lamps, say of 8 cp., arranged to the best possible advantage for the most effective lighting of the space; the secondary room to be lighted by the lamps to be compared, arranged also for the most effective illumination. An equally effective illumination in each room is then secured by switching on or off lamps in the primary room. The energy supplied to each of the two rooms being measured when adjustment is secured, these data will then represent comparatively the efficiency of the sources of illumination compared. It is stated that accuracy within 5 per cent. is obtainable with this method. That such a method would appeal to the lay user of artificial light may be taken for granted, though it would perhaps not satisfy the physicist any more than a town clock would satisfy an astronomer. None will deny that what is sadly needed is a yard stick for illumination; what is now usually offered may be likened to an offer to a perspective user of measure of length—who would be satisfied with a 5-cent graduated stick—of a certified standard necessitating a microscope to locate the lines thereon fixing the desired length.

But it should be added that the superior economy of the Nernst lamp as registered at the meter is only a part of the claims it can put forth for recognition. The human eye does not take cognizance alone of meter efficiency, but applies criteria of its own. Owing to the approach of the Nernst light to the quality of daylight, the eye is better accommodated to illumination from this source, with a result that it will distinguish objects much better with the same measured illumination than in the case of a source not possessing this quality. To put an extreme illustration, one can easily imagine that a more satisfactory aspect of, say, a room would be obtained with the light of a single candle than with that from a 50-cp. source giving forth blood-red rays. That the beautiful quality of the Nernst light would make it a factor in the lighting field were its cost even much larger than that of its competitors less favored in this respect, is evident when we look back and note the course of the various modern illuminants—the progression from the candle to oil, from the latter to gas and finally to the incandescent lamp—in each case the quality of light dispossessing a cheaper source.

REGULATION.

One of the charges which has been made against the Nernst lamp is that it requires a closer regulation of circuit than the incandescent lamp. If this were qualified by adding that the incandescent lamp superior in this respect is a 4-watt lamp, the charge might perhaps be maintained, but in that case it would also hold good as against the 3.1-watt incandescent lamp. In point of fact, it is claimed for the Nernst lamp that a continuous five per cent. overload will not appreciably shorten the life of the glowers, whereas, on the other hand, accepted curves of incandescent lamp performance show a decrease in life of 60 per cent. under the same condition. At the present day the matter of proper regulation of circuit voltage is beginning to attract the attention which its importance demands, and the Nernst lamp has not been found wanting where this attention has been given; and where it is lacking the deficiency is equally fatal to the high-efficiency incandescent lamp. If improvements made in the electrical field during the past fifteen years had been subjected to judgment on the basis of their fitness with respect to the practice of the poorest central station, many of the most valuable advances of the period would be yet awaiting recognition. One of the benefits which the Nernst lamp will confer on the central station industry will be in strengthening further the present movement toward proper circuit regulation, in which benefit it will itself participate as only one factor among many making toward better central station financial returns.

MAINTENANCE.

Unlike the incandescent lamp, the frame and connections of the Nernst lamp form a permanent structure having an indefinite life, but its perishable parts have from time to time to be renewed. Of these the ballast has a life so long, averaging 25,000 hours, that in an organization for maintenance it plays little part. The heater has also a very considerable life, the period averaging about 8 months in ordinary use. The glower, however, like the incandescent lamp filament, has a practically definite term of use, at the end of which it would be advisable to replace the glowers whether burnt out or not. 800 hours are given as the guaranteed life on 60 cycles.

Two systems of maintenance for the Nernst lamp have been employed. In the one, all the installations within a certain radius are maintained for a fixed sum per month from a central maintenance bureau, which may be directly in control either of the Nernst Lamp Company or its central station customer on whose circuits the lamps are operating. This department of the lighting company is analogous to the meter department which is now becoming an auxiliary to all well-managed plants. Such an organization involves the services of an inexpensive class of help, consisting of an inspector who alone or with one or more assistants in the case of the larger plants, operates the maintenance system, visiting all installations periodically; for example, commercial installations may be visited weekly, and residential installations once per month, the user being instructed how to act in contingencies which may arise during the absence of the inspector. A complete stock of Nernst lamp parts is carried in the repair department. The work to be done here is so simple, owing to the careful provision made in the design of lamp details for easy renewal, that a boy or girl can in a short time acquire the necessary skill.

The second system is especially applicable to the larger installations and those in isolated localities. In these cases, the maintenance work may frequently be entirely taken care of by the building janitor or electrician, who has previously received some instruction and training, either at the company's works or from an expert repairman. Suitable quarters would be provided in the building in which a limited stock of repair parts and facilities for renewal work would be available.

The total cost of maintenance under these conditions will be comparatively low, provided the maintenance work is executed in a systematic manner; a certain portion of the day being given to inspection, with a complete inspection of all lamps installed, the repairing of defective holders being afterwards done in the repair room. We are informed that the results obtained by the company from a number of prominent installations go to show that the cost of maintenance of the smaller lamps approximates that necessary for incandescent lamps, and the cost for the multiple glower lamp is practically the same as that for standard enclosed arc lamps.

Electric Lighting Chicanery.

The following item was printed in the New York *Evening Post* in a recent issue. It is not without its humorous side: "Comparatively few persons know why an electric lighting company is so exceedingly kind to its customers as to give them new incandescent lamps without charge in exchange for those which have burned out. The employees are always so polite, almost anxious to make the exchange. Any one can find out the reason by burning new, high-priced lamps for a month, and the next month the lamps the company gives in return for old ones. His bill will show that the reason, from the company's point of view, is an excellent one. The lamps supplied by the companies are invariably 'renewed' lamps; that is to say, old lamps made new by a delicate but not expensive process; and 'renewed' lamps burn more current—much more. The millennium is not yet here." There is deep villainy for you. As a matter of fact, we should be glad to get "renewed" lamps exclusively; at least no objection would be raised. In view of the fact that they have been in use, the occluded gas in the platinum, etc., have been pretty thoroughly disposed of, and such lamps are, therefore, quite likely to beat new ones all hollow for economic efficiency. But their use is vastly exaggerated. One local company we could mention, out of over 1,500,000 lamps bought had only 6,000 "renewed," and that is probably about the general ratio.

Recent Electrochemical Developments.

PRODUCTION OF SODIUM HYDROXIDE.

Two patents granted on May 10 to Mr. Blackmore, of Mt. Vernon, N. Y., relate to the electrolytic production of sodium hydroxide. The process described by him in one of the patents is in its essential points similar to the well-known Castner-Kellner mercury cathode process, which is in actual operation on a large scale. Various modifications have been suggested for this process, relating especially to the method by which the cathodically formed sodium amalgam is removed from the electrolyzing cell for the production of sodium hydroxide in another cell. For instance, Bell proposes to use for this purpose the atmospheric pressure of the gases developed in the cell; his process has been tried on a large experimental scale by the Pennsylvania Salt Manufacturing Company at Wyandotte, Mich., during the last three years, but it does not seem to have yet been reduced to industrial practice. Blackmore in his present patent produces the movement of the mercury and amalgam through the various vessels in his apparatus solely by the differences of level of the various bodies of mercury and amalgam. These differences are maintained by a suitable adjustment of a float-fed and a float-controlled outlet, and of the height of the connecting pipes. The mercury, after the sodium has been removed from it, is pumped back into the first vessel which supplies mercury to the cathode in the electrolyzing cell.

The second patent of Mr. Blackmore refers to the production of sodium hydroxide from the cathodically formed sodium amalgam or sodium lead alloy (in the latter case a molten lead cathode being used as in the Acker process). In what follows we assume a molten lead cathode. Mr. Blackmore's apparatus consists essentially of an electrolyzing vessel with a diaphragm dividing it into two compartments. The anode compartment is in the center and contains fused sodium chloride on top of a floating diaphragm, which consists of magnetite broken into small fragments. This diaphragm floats on the molten lead cathode which extends into the outer vessel. The specific gravity of the diaphragm is greater than that of the molten electrolyte in the anode compartment, and smaller than that of the molten lead cathode. The lead sodium alloy produced by electrolysis, being lighter than lead, continually arises to the surface of the molten lead, and may be drawn off there. The author, however, considers it preferable to change it into hydroxide, and has found the following method suitable. Molten sodium hydrate is injected in a plurality of fine streams into the molten lead-sodium alloy, and is reduced by the sodium to sodium oxide with evolution of hydrogen which passes off. The sodium oxide arises and flows on the surface of the cathode and, remaining in a molten condition, it is continuously drawn off. To facilitate the oxidation of the sodium, a layer of loose granular conducting material, like iron, magnetite of ferro-silicon, is arranged at the surface of the cathode. This loose material serves to distribute the streams of sodium hydrate and bring them in thorough and intimate contact with the sodium in the alloy. "The oxidizing reaction is facilitated by the innumerable local couples due to the contact of the sodium and the relatively negative particles of iron, etc."

BATTERY INVENTION.

A patent granted to Mr. C. J. Reed, of Philadelphia, refers to the construction of a plate suitable for Planté formation. The plate consists of numerous corrugated panels with intervening strengthening ribs and side ribs, the exposed surfaces of the panels being corrugated so as to have a large surface. The plate is made by passing molten lead between corrugated rolls and subsequently subjecting the plate to lateral edgewise compression in order to reduce the grooves to the smallest practicable width.

A patent granted to Messrs. R. Fortun and E. Semprun, of Madrid, Spain, relates to a storage battery, the feature of which is the active material of the positive electrode. This active material is produced by electrolysis, between lead electrodes, of a saturated solution of oxide of lead in a lixivation of potassium hydroxide, rock candy and neutral potassium tartrate. By this action a brown substance is deposited on the anode for which the claim is made that 100 grams of this substance are capable of fixing 369 grams of oxygen. This active substance is used for the positive pole electrode in an accumulator with a solution of 17 parts of lead nitrate in 100 parts of water, acidulated with pure nitric acid until the solution registers 20° Baume.

A patent granted to Messrs. J. Noble and E. L. Anderson, of St. Louis, represents a new attempt at utilizing the heat of oxidation of carbon for the production of electrical energy. The cell consists of an aluminum plate and a carbon plate with an electrolyte of nitric acid, heated to 150° F. The cell is claimed to have an e.m.f. of 1.5 volts, the current flowing in the solution from the aluminum to the carbon. The following actions are assumed to take place in the cell. Oxygen is evolved at the aluminum anode without attacking it, while at the cathode the nitric acid is reduced to nitrogen peroxide, which oxidizes the carbon cathode, thereby forming carbonic acid gas and nitrogen oxide gas. The nitrogen oxide gas unites with the oxygen evolved at the anode and forms nitrogen peroxide gas, which passes into a condenser filled with a mass of moist carbon or coke, and is therein condensed to nitric acid, returning then to the battery. The claims of the inventors that without destruction of the aluminum plate electrical energy is produced at the expense of the change of the carbon plate to carbonic acid gas and at the expense of heat supplied from the cathode.

New Telephone Patents.

If the general activity in any field of industry may be measured by the activity of its inventors, then truly must telephony be in a prosperous state, for we have at hand this week for consideration an extraordinary number of telephone patents. These treat of a great variety of subjects, as might be expected, but for convenience they will be grouped together under topical headings in so far as possible. The first group will include patents bearing on central office apparatus.

CENTRAL OFFICE APPARATUS.

The heat coil or sneak current protector forms the subject of three patents. These all apply the same principle, viz.: the shortness of fusible metals when slightly heated. The application of the principle is, however, made in two different ways. In Fig. 1 is shown sectional views of all three new coils.

At the right is a heat coil patented by M. Setter, of Chicago. As will be noted, on one end there is a hinged plate to which a stud

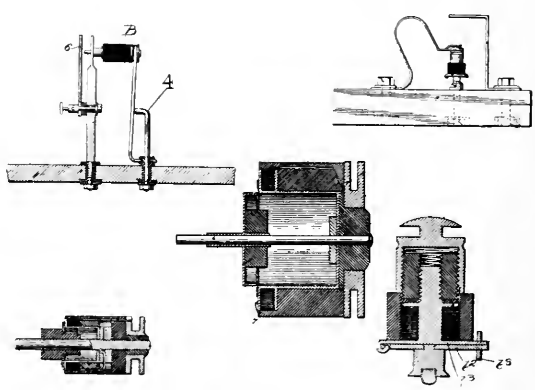

FIG. 1.—TELEPHONE CUT-OUTS.

is attached. Normally, a ring of fusible metal encircling projections from the pieces b^2 and b^3 holds them together. In this condition the coil is adapted to be mounted in a spring holder which strives to pull the ends apart. When an abnormal current passes in the circuit, which is led through the heat coil, from one terminal button to the other, the heat generated so affects the solder ring, b^8, that its tensile strength is impaired and it breaks. The hinge at once opens, giving, as it does so, an inclination to the stud, b^1, such as to cause it to escape from its holder and thereby breaking the circuit, which at once becomes grounded against the stop for the spring terminal. The other two heat coils cause a shearing of solder under exactly similar circumstances, to effect an operation of the switching members. One of these is shown at the middle of Fig. 1, while the other, together with a mounting suitable for either, is shown at the left. In both the heating coil proper is in annular form, surrounding a cup within which a plunger may be forced. The plunger is normally blocked, however, by a washer of solder, which lies between its bottom and the mouth of the cup. The tendency of the mounting springs is to cause the plunger to clamp the washer, as a plate between a punch and die. With slight heating of the coil shearing takes place, the circuit opening at the point 4 and grounding at the point 6. The chief point of distinction between the two coils of this type lies in the substitution of an insulating shearing plug in one, that shown on the left, for the metal shearing plug of the other. Of these coils Mr. Setter is the inventor of one and H. P. Claussen the inventor of the other. Both have assigned their right to Messrs. P. C. Burns and J. G. Shimsen.

A. M. Knudsen, of Chicago, has produced a combined jack and drop for switchboards in which the drop shutter is mechanically restored by the insertion of a plug into the jack in answering the call. The restoring is accomplished by a pivoted member, one end of which hangs in the path of the plug in a manner to be rotated by the insertion of the latter, while the other end engages an extension of the drop shutter so as to restore the shutter as the rotation takes place.

A second mechanically restoring annunciator is that patented by Albert Corliss, of Chicago. In this the target or shutter revolves on a pivot, the signal being displayed before a window in the casing which holds the annunciator and jack in proper relation. The restoring is accomplished by a spring member which engages a stop on the rotating shutter. This spring is elevated by the entering plug, and its end engaging the stop causes the shutter to rotate into normal position, where it becomes locked pending the arrival of another call. The American Electric Telephone Company has been assigned this latter patent.

SWITCHBOARD CIRCUITS.

Switchboard circuits are represented by three patents. One of these shows a rather simple common battery system, while the other two relate to the divided multiple switchboard. The common battery system patent has been granted to Mr. D. W. C. Tanner, of Chicago. The circuit is shown in Fig. 2. For the purposes of explanation it will be assumed that a call is started from the left-hand station. The removal of the receiver from the hook closes the circuit through relay *a*, which, responding, energizes the line lamp and busy test for the calling subscriber. The operator responds in the usual way with plug *t*, the answering plug of the connecting cords shown. This extinguishes the lamp, as the battery, b^1, opposes battery *b* and reduces the potential around the lamp sufficiently to do so, this reduction of potential, of course, being traceable to the series resistance, *c*. It will be noted that no supervisory light is shown. This is because the line lamp of the calling line serves this purpose; to this end it is arranged so that once extinguished by the response of the operator, it will not relight until both subscribers have hung up.

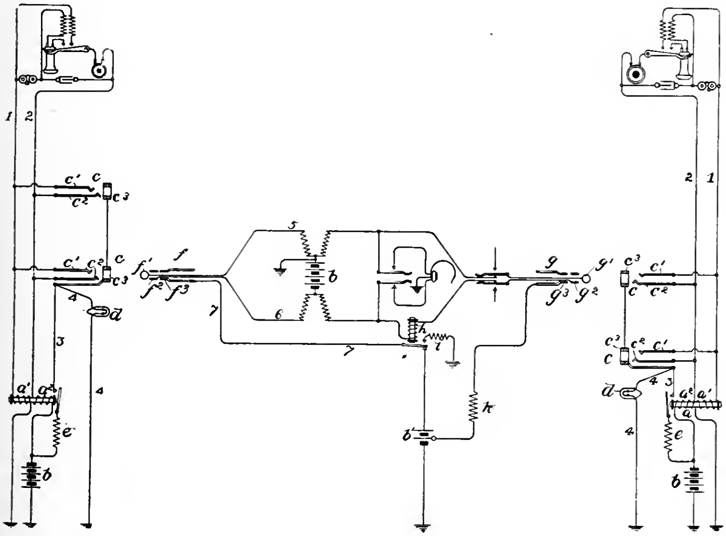

FIG. 2.—TANNER SWITCHBOARD SIGNAL.

Suppose, now, the operator to proceed with the connection by plugging into the desired line. This will put a busy test on this line from the tap, *k*, but will not cause the called line's lamp to glow, as insufficient potential is provided. Now, the called subscriber answers, energizing his relay, *a*. Still his lamp fails to glow, as tap *k* forms a shunt about it. When the subscriber answered another change occurred, as relay *h* was energized and connected the shunt, *l*, around the calling subscriber's lamp, *d*, instead of the battery, b^1. Now it is evident that *d* will only glow when both subscribers have hung up, for if the calling subscriber alone does this no battery connection exists in the lamp circuit; while if the called subscriber hangs up alone there is a return to the battery shunt, b^1. If both hang up, battery b^1 alone is effective and this lights the signal.

The circuits for divided multiple boards are both the work of E. H. Smythe, of Freeport, Ill., and show two alternative methods of accomplishing his desired result. With the divided multiple switchboard of the type in question, each line is provided with one answering jack and line signal for each division of the multiple, and in signalling he must operate that one of his signals which is associated with the division corresponding to the desired subscriber's number. At times it is found that a subscriber will call in error, and noting his mistake remakes the call to the proper division. Under such circumstances confusion would, of course, arise unless some means of preventing the co-existence of two signals from the same line. Mr. Smythe overcomes the difficulty by making the signal relays, which cause the display of the signals, interconnecting in such a manner that the one last energized disconnects or de-energizes the other. Therefore, the corrected signal at once and automatically extinguishes that made in error. Both Mr. Smythe's and Mr. Tanner's patents have been assigned to the Western Electric Company.

SUBSCRIBER'S STATION APPARATUS.

Undoubtedly quite frequently telephone users are disturbed for fear that what they say into the transmitter may be overheard by those in the immediate neighborhood. For some the sound-proof booth serves every purpose, but this because of the inconvenience of entering it and the space it occupies is not always satisfactory. To overcome this difficulty a transmitter hood has been patented. This is a metallic box adapted to be fastened upon the transmitter, and of such size and shape that when the face is closely pressed against it the lips will be in proximity to the transmitter mouthpiece. The box is of small size, the edge of the aperture coming in contact with the chin, cheeks and upper lips only. The edge is provided with a rubber cushion and is shaped to fit the face. As it is necessary to keep secret but a portion of one's conversations, the sides of the box, four in number, are made folding and are so controlled by a spring that they may be folded back. R. D. Fannon, of Chicago, is the patentee of this apparatus.

A new telephone set has been invented by Messrs. S. C. Houghton, of San Francisco, Cal., and F. M. Potter, of Syracuse, N. Y. Vertical slide bars support an adjustable frame upon which both transmitter and receiver are carried. The receiver is upon the end of an arm consisting of two bars, which are insulated from each other and serve as the conductors to the receiver coil. The receiver is held in a position to the side of and in front of the transmitter ready for use. A slight pressure upon it in a horizontal direction serves to throw the switching device, while a semi-automatic electromagnetic switch enables one to hold the line conveniently while leaving the instrument.

For use in damp places, or where water is likely to be dashed about, as on shipboard, a water-proof subscriber's set is advisable. Such is one invented by Alfred Graham, of London, England, which has been recently patented. The casing is of metal and all apparatus is contained therein, entirely protected except when actually in use.

Mr. A. W. Hill has brought out a novel transmitter in which one block of carbon serves as the body of the casing and the stationary electrode. A sectional view of this transmitter is shown in Fig. 3, which indicates how the diaphragm, mounted between rubber pads, is clamped to the carbon block by the face plate. Within a central and deeper recess in the carbon block the microphonic button is built up. The recess is lined with an insulating tubular bushing, which contains the granular carbon. The bottom of the recess forms the rear electrode, while the front electrode attached to a metal backing slides within the bushing, the joint being jacked by a felt ring.

The two remaining patents to be included under this head describe

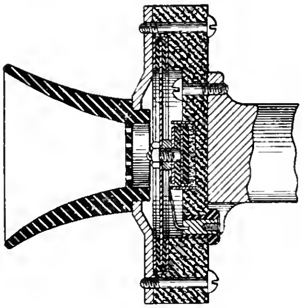

FIG. 3.—HILL TRANSMITTER.

respectively a receiver and a ringing generator. The novelty in the receiver lies in the method of mounting the magnet within the casing. The casing is in three parts, a joint being made in the body near the bell. The magnetic system carries a collar secured to it near the coils, and this collar forms the coupling for uniting the two parts of the body of the casing. The distance which the collar is screwed into the bell piece of the casing determines the air space between the diaphragm and poles. The tail piece is then screwed up like a lock nut securing the whole in adjustment. W. C. Runge has been granted the patent for this.

MISCELLANEOUS.

While the effects of electrostatic capacity have been brought well under control by the Pupin system of loading conductors, all other steps towards ameliorating its detrimental qualities are interesting. Mr. J. S. Richmond, of New York, aims to do this in his transmission system described in two recent patents. Mr. Richmond argues that with a metallic circuit in a cable of conducting material, i. e., a conducting shell, all capacity between the individual conductors and the shell will be obviated if the potential of the shell be kept a true mean between the sum of the potentials existing on the conductors at all points. He accomplishes this by finding the inductive neutral of each end of the line and grounding this. Such a process, of course, renders it necessary to use double-wound apparatus of that type designated as "split" wound, but this would not weigh against the system if the gain in transmission is found to be material. Any one who has tried to solder a wire to a gas or water pipe, or to make a secure joint by wrapping for the purpose of obtaining a ground connection, appreciates what a boon was the introduction of sheet-metal ground clamps. An improved ground clamp of this type readily adjustable to different sized pipes has been patented by Messrs. F. P. Fuller and J. J. Walsh, of Yonkers. In this clamp the actual connection seems to be made chiefly between the clamping screws and the pipe, the metal band serving merely to hold the screw ends against the pipe.

Many already know that method of handling distributing wires wherein they are carried in rings supported by a messenger strand. Such a scheme is most successful. However, it has been found advisable to hold the rings at definite distances apart by an auxiliary fastening, such as a wire or yarn running parallel with the messenger and independent thereof. F. C. Locke has obtained a patent for a method of fastening the rings based on these principles. A train telephone system for communicating to and from and between moving trains, a step-by-step selective system, and a special arrangement of telephone incandescent lamp bulbs for exhaustion, comprise the subjects of the remaining three patents. These have been invented respectively by Messrs. C. G. Otwell and S. H. Melvin, Mr. C. A. Anderson and Mr. A. D. Whipple. For information concerning them the reader is referred to the patents as the subject matter does not seem of sufficiently general interest to warrant discussion here.

CURRENT NEWS AND NOTES.

FEMALE STREET CAR CONDUCTORS.—A Springfield, Ohio, despatch dated May 17, says: After six years of experiments the officers of the street railroad company at Chillicothe have decided that the women conductors must go. The women were satisfactory, except that they were not strong enough for switching work. Switching at home would be more in their line, it would seem.

CELEBRATING TELEGRAPH ANNIVERSARY.—The Postal Telegraph Cable Company is to celebrate this week in New York the tenth anniversary of the opening of its central office building and the sixtieth anniversary of the first telegraph message. The exercises will take the form of a conference of the leading officials from all over the country, with a banquet on May 24 at the Hardware Club. The previous night there will be a large theatre party at Wallack's to see "The County Chairman." Mr. C. P. Bruch is organizing the functions.

DETECTING DIAMOND IN STOMACH.—A news note from Texas states that a thief there swallowed a diamond worth $250, and then was arrested and taken to jail. Investigation by means of the X-ray revealed that it had "become imbedded in the wall" of the man's stomach. The owner of the diamond offered to pay for a surgical operation, and it was performed with entire success, so that the owner has recovered his diamond and the thief was still alive at last accounts, with good prospects of recovery. At least, so the story goes in the dispatches.

COMMERCIAL AUTOMOBILE TESTS.—As a result of the service tests of motor wagons made under the auspices of the Automobile Club of America, gold and bronze medals have been awarded to the electric delivery wagons of the Pope Motor Car Company to carry from 1,000 to 2,000 pounds; a gold medal to the electric truck of the Electric Vehicle Company, to carry between 4,000 and 5,000 pounds, and a gold medal to the gasoline-electric truck of the Fischer Motor Vehicle Company, to carry from 8,000 to 10,000 pounds. The committee will presently issue a full report on the subject of the tests.

WIRELESS TELEGRAPHY AT THE FRONT.—Capt. James, the efficient correspondent of the New York and London *Times* at the seat of war, has been silent for some time lately. He has resumed his work, but in his wireless dispatches admits that Japan had temporarily warned him off the fighting zone, just as Russia had done, although in a slightly more polite way. "My position was difficult in the extreme. I was threatened with capital punishment by one belligerent and warned off the high seas and neutral waters by the other. Only two courses remained open: Either to submit to the Japanese wishes or claim the right of a neutral flag on the high seas, in which case the only control of either belligerent would be *force majeure*. In deference to former courtesies on the part of the Japanese, I took the former course."

SELECTIVE SIGNALLING BY RESONANCE.—Dr. M. I. Pupin is to lecture before the New York Electrical Society on May 25 at the Havemeyer Building, Columbia University, on "Selective Signalling by Electrical Resonance." Dr. Pupin will explain the principles and the essential elements of this system of transmission. These elements are: The multifrequency alternator, the transmitter, the distributors, the resonators, and the rectifiers. At the special request of the U. S. Patent Office Commissioner, Dr. Pupin has prepared an exhibit for the pavilion of the U. S. Patent Office, at the St. Louis Exposition, illustrating by a complete model the transmission of telegraphic messages by alternating currents of various frequencies, the receiving and the transmitting apparatus being electrically tuned to the frequencies which they are intended to receive and transmit. This exhibit will be shown at the lecture. The lecturer will discuss at some length the application of electrical resonances on which the development of wireless telegraphy may so largely depend.

RADIUM FOOD PRESERVATIVES.—At a recent meeting in New York City of the Food Standard Committee, L. Lieber, of H. Lieber & Co., New York chemists, spoke in defense of chemicals used in coloring foods. He said that they commonly preserve the food while exposed to light and cease to act when out of the light, so that when the food is eaten there is no interference with digestion. In his opinion these substances are much superior to the so-called preservatives. Mr. Lieber also said that the time is coming when radioactivity will entirely supplant the chemicals now used for preservatives.

POOL ROOM TELEGRAPH SERVICE.—The following is part of a series of resolutions adopted by the Western Union Telegraph Company: "The Executive Committee hereby instructs the officers and employees of the company to withdraw immediately the service of racing news from any place or places that shall be designated as unlawful pool rooms by the Commissioner of Police of New York City or the District Attorney of New York County, accompanied by a request to make such withdrawal, and to furnish hereafter such racing news only to such applicants as shall give assurance that it is not to be used for pool room purposes." The company has since discontinued its race news service and the New York Telephone Company has promised to take out its telephones in pool rooms.

GOOD BUT NOT CHEAP.—Mr. Godfrey L. Cabot, writing from Boston, Mass., under recent date to the *American Gas Light Journal,* inquires: "Perhaps some of your readers can kindly tell us whether paraffine paper has ever been tried as a protection of pipes from electrolysis. It seems to me that, by neatly fitting paraffine paper around the pipe, and wrapping outside this a bandage of cloth, soaked in coal tar pitch or asphalt, a protection could be obtained against electrolysis under the conditions usual in our streets. Care could have to be taken that the inner layer was impervious, as asphalt itself is not a sufficiently good insulator to give the required protection. I hope that some one of your many readers will be able to answer this question. Six years ago I investigated the subject of electrolysis in many European countries and found that in many places the street railway companies were compelled by law to bond their rails in an efficient manner, and that this greatly diminished the difficulty; but we are not all protected in this way."

WIRELESS TELEGRAPHY AT SEA.—Mr. G. Marconi arrived in New York City from England last week on a trip to test some new apparatus. On the Cunarder *Campania* Mr. Marconi was accompanied by his assistant, G. S. Kemp, two special operators, two secretaries, and Mr. W. W. Bradfield, chief engineer. The inventor had a state room on the port side of the vessel, and in it he installed his key, the wires leading to the truck of the foremast. On leaving Liverpool the vessel was put into communication with the shore stations at Poldhu, Seaforth Sands and Crookhaven. During the voyage the vessel logged 3,158 knots. According to his statement on the subject, Mr. Marconi continued to send messages to the Poldhu station until he was 1,700 miles at sea. After the vessel had passed the 1,500-mile mark he sent messages to Cape Breton, cutting off Poldhu after 1,700 miles. Everything sent to the land stations was received, and the only mistake made was in the name of Gen. Sir H. C. Wilkinson, a passenger on the *Campania,* whose name at a distance of 1,600 miles was received "Wilson."

ELECTRIC SMELTING OF IRON.—Dr. Haanel, Dominion Superintendent of Mines, who recently went to Europe to investigate the methods in vogue in that part of the world, of electric separation of iron ore, has just received a consignment of samples of gray, white and mottled pig iron, all having been reduced from iron ore direct by the aid of an electric furnace. Samples of cast-iron castings are also exhibited as made from the molten metal taken from the electric furnace. These castings, from but once smelted metal, are stated to be in quality equal to any cast-iron castings produced. The grey pig iron is a superior grade of foundry iron. This grade pig can be also used for the purpose of conversion into steel by the acid process. Dr. Haanel is hopeful of the process being very useful in converting the immense iron ore beds of Canada into marketable metal. The process is particularly applicable to Canadian conditions, viz.: abundance of water power for electricity, incalculable quantities of ore and not sufficient coal near to make ordinary smelting pay. Dr. Haanel thinks that the process may revolutionize separating processes, as it can be applied to all classes of metals.

LETTERS TO THE EDITORS.

The Metric System.

To the Editors of Electrical World and Engineer:

SIRS:—In view of the fact that your issue of May 7 seems to criticise the tone of our circular letter eliciting the opinion of the members of our Association on the compulsory metric system bill, I would respectfully suggest as a means, and perhaps the only means, of representing that you yourself intend to be perfectly fair in your discussion of the matter, that you print for the benefit of your fair-minded readers the circular letter in question, a copy of which I enclose herewith.

NEW YORK. MARSHALL CUSHING,
Secretary, National Association of Manufacturers of the United States of America.

[We print below the circular letter referred to.—EDS.]

"There has been such a large increase (nearly 200 per cent.) in the membership of the Association since the vote upon the adoption of the metric system was taken a year and a half ago, that your Executive Committee has thought it best to repoll the Association on this important matter. You are, therefore, requested to signify your sentiments upon the enclosed ballot, and sign and return it at once to the General Office.

"Since the first ballot was taken the adverse vote then expressed has been concurred in by the following associations: The American Society of Mechanical Engineers, the Railway Master Mechanics' Association, the Master Car Builders' Association, the Furniture Association, the National Metal Trades Association. Similar action had already been taken by the Association of Machine Tool Builders, the Engine Builders' Association, the Society of Naval Architects and Marine Engineers, the Society of Heating and Ventilating Engineers and the Providence (R. I.) Society of Mechanical Engineers.

"The metric system bill was withdrawn from the last Congress by its friends because of the shortness of the session, but with the understanding that it is to be pressed again at the present session. This bill reads:

"'That on and after the first day of January, 1904, all the departments of the Government of the United States, in the transaction of all business requiring the use of weights and measures, excepting in completing the survey of public lands, shall employ and use only the weights and measures of the metric system; and on and after the first day of January, 1907, the weights and measures of the metric system shall be the legal weights and measures of the United States.'

"Please note that this ballot does not involve an opinion on the merits of the system. You are only asked to say if you want it adopted by law."

To the Editors of Electrical World and Engineer:

SIRS:—In an editorial in your issue of May 7 you say that in addition to the three engineering bodies named in the publication of the National Association of Manufacturers as favoring the metric bill, there are at least three more among the most prominent in the country that might have been included in the list, their pro-metric votes having been officially published. I deny this statement and challenge you to print the names of the bodies.

NEW YORK. ANTI-METRIC.

[The bodies referred to are the American Institute of Electrical Engineers, American Electrochemical Society and the Franklin Institute.—EDS.]

The Harmful Suppression of Inventions.

To the Editors of Electrical World and Engineer:

SIRS:—Your editorial of April 16 concerning the working of patents brings up a question of the greatest interest. It is important, however, to distinguish between the proper suppression of inventions and their harmful suppression. It is proper that the owner of expensive machines should acquire a patent covering cheaper machines for making the same product, and should suppress the invention for a limited term, rather than scrap all his expensive machinery at once. No serious harm is done to the progress of science and useful arts in the United States, since by the end of the term of the patent the manufacturer may be compelled by competition to adopt the simplified machinery. If he does not do so, others will. For this benefit to the country the patent owner is entitled to the reward of a monopoly for a limited time either by suppression or by exclusive use.

The more harmful case is the suppression of inventions in the United States which are being worked in a foreign country. During the seventeen years of the monopoly, the foreign manufacturers are continually making practical improvements. The basic invention is not in practical use in this country, and such improvements are very unlikely. At the end of the seventeen years the original invention is public property here, but is not commercially valuable as compared with the improvements which are still controlled and used only in the foreign country. There is no incentive to the establishment of a new industry in this country under such conditions. This is exactly what has occurred in the case of dye-stuffs and other high-grade chemicals. The German manufacturers, the American market being secured by patents, have established a supremacy which it will be impossible to overcome for many years. The same thing is apt to occur in the establishing of any new industry in future. The constitutional provision upon which the patent laws are based applies to the promoting of the progress of science and useful arts in the United States. This use of a patent has only the effect to retard such progress.

This violation of the intention of the constitution should be a good ground for repealing a patent, but the difficulties in the way of repeal are so great that it is doubtful if it will ever be tried. It remains, therefore, for Congress to provide a suitable remedy, such as an alternative requirement of a bona fide working of the invention in the United States (accompanied, perhaps, by a prohibition of importation) or the granting of a license to others on reasonable terms. If this is not done there will be a number of industries developed by purely artificial means in other countries and never seeing the light of day in this country.

New York City. Domingo A. Usina.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

Dynamos, Motors and Transformers.

Design of Electrical Machinery.—Hunt.—A paper read before the Liverpool Engineering Society. The author first discusses direct-current machines. Since commutation becomes more difficult the higher the voltage it is advisable that in order to reduce the number of designs as much as possible, at least for small machines up to say 100 hp, the armatures should be designed for 500 to 550 volts; it will then be quite easy to obtain excellent commutating qualities for all lower voltages. To determine the commutating qualities of a machine, the author thinks that it is only necessary to consider the armature ampere-turns per pole, and the length of the armature core, to arrive at a satisfactory basis for calculation. The e.m.f. induced in a short-circuited coil opposing commutation may then be said to be proportional to the armature ampere-turns per pole, the number of turns per commutator part, the speed of the machine in revolutions per minute and the length of the core. The author gives some numerical data on this subject, especially in connection with a special machine, the details of which are given. Concerning commutator losses he says that consulting engineers often specify a maximum value for the current density at the contacts of carbon brushes and commutator, irrespective of the voltage and speed at which the machine may be operated. This often results in the commutator losses being greater than need be. He points out that for any given peripheral speed at which a commutator may be running, there will be a certain current density at the contacts of the brushes which will give a minimum value of the commutator losses. To make these losses a minimum, the contact surface of the brushes should be so chosen that the loss due to friction is half that due to the C^2R loss at the contacts. He then discusses alternating-current machines and says that the value of the power factor and the overload capacity of a motor is almost entirely governed by the demagnetizing component of the rotor current. At no load this is practically nil, but as the torque is increased, it grows with it, slowly at first, until the load is reached at which the power factor of the machine has its highest value. After this load has been passed, the rotor magnetizing component increases more rapidly until, when the motor is developing its maximum torque, it attains the same value as the component of the rotor current with which it is in quadrature. This demagnetizing current depends upon three things: First, the coefficient of leakage of the stator winding; second, the coefficient leakage of the rotor winding; third, the ohmic resistance of the stator winding. Instead of using the coefficients of leakage, the author finds it simpler to work out the coefficient of mutual induction between stator and rotor windings and then to estimate the coefficients of self-induction of the stator and rotor windings. In order to show the effect of the demagnetizing component of the rotor current upon the performance of a motor, details are given of the tests of a 20-hp machine.—Lond. *Elec.*, April 29.

Regulation of Alternating-Current Motors.—A note on a method of Lahmeyer & Co. for the regulation of non-synchronous alternating or three-phase current electric motors, and rotary converters. It is proposed to regulate the speed by inserting choking coils into the rotor circuit, instead of wasteful resistances, and to regulate the choking effect by varying the reluctance of the magnetic path of the choking coil. This may be done by more or less saturating this magnetic path by a variable number of continuous-current ampere-turns. The amount of these may be regulated either by hand or by automatic means, so as to maintain a constant speed of the motor. A purely electric method of automatically regulating the speed is as follows: The choking coil, besides being wound with the leads from the rotor, is also wound with two auxiliary coils, which oppose one another. One is permanently fed by continuous current from a constant-pressure supply, while the other receives its current from a small continuous-current generator (or from the generator proper in the case of a motor-generator) driven by the motor. If, now, the motor exceeds its normal speed, the voltage of the auxiliary continuous-current generator driven by it will rise, and the magnetizing effect of the bobbin, which is permanently excited, will be opposed to a greater degree than before. The permeability of the magnetic circuit of the choking coil will increase in consequence, and the choking effect will become more pronounced—i. e., the motor speed will decrease, and, if the arrangement be properly adjusted, the speed will be brought back to its proper value. If the motor speed decreases, the reverse actions take place.—Lond. *Elec.*, April 29.

Equipotential Connections.—Müller.—The conclusion of his article. He has found in practice that machines which, without the use of equipotential connections, offer great difficulties as to sparkless commutation, would work absolutely satisfactory as soon as such equipotential connections were introduced. He gives algebraical rules how to calculate and introduce these connections.—*Zeit. f. Elek.* (Vienna), April 24.

Output Coefficient.—Pensabene.—A communication on the output coefficient of induction motors. He thinks that the only useful and suggestive formula is the old $D^2L\,R\,\phi$, which is not an empirical one. To determine the nature of the coefficient, ϕ, he gives its expression by an analytical explanation of the fundamental formulæ used in induction motor designs.—Lond. *Elec.*, April 29.

Tests of Direct-Current Machines.—Smith.—A paper illustrated by diagrams giving a review of convenient tests of direct-current dynamos and motors.—Lond. *Elec. Rev.*, April 22, 29.

Lights and Lighting.

Mercury Arc Lamp.—Paweck.—A description of a mercury arc lamp which seems to be mainly of historical interest since it is claimed to have been the first lamp of this type with an automatic starting device. The lamp is shown in Fig. 1. *a* is the tube in which the arc is formed, connections being made by the platinum wires, *c*, at the two terminals, *b*. This horizontal tube can be revolved around the vertical axis, *mm*, connection to the source of current being made by the method clearly indicated in the illustration. *h, i* and *d, g* are platinum wires dipping in mercury. When the circuit is closed, the current passes through the mercury in the middle part of the glass tube, *a*, but at the same time a small electromotor begins to revolve the glass tube, *a*, and the mercury in it is then driven by the centrifugal force to the ends of the tube, *a*, and the arc is started. The operation is stated to be quiet and noiseless, the revolving arc giving the impression of a horizontal lighted disc. The speed of rotation appears to have been small. This lamp was built at a suggestion of Kellner, who has later used amalgams instead of pure mercury in order to improve the color of the light. For instance,

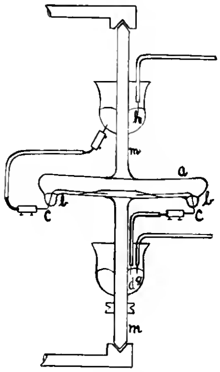

FIG. 1.—MERCURY ARC LAMP.

potassium amalgam gives a red tint. At the same time the use of an amalgam represents a new method of starting the lamp, since when the lamp is not lighted a thin film of amalgam is formed along the internal wall of the tube, which acts as a conducting bridge between the two electrodes, when the lamp is started. Afterwards this film is vaporized and the arc is formed. In another type of Kellner lamps, a plunger is used for starting. Credit is briefly given to the work of Hewitt.—*Zeit. f. Elektrochemie*, April 29.

Miner's Lamp.—A description of the Neu Catrice portable electric lamp for miners. The base of the lamp consists of a box of sheet lead containing two accumulator cells made of transparent celluloid or semi-plastic India rubber. Each cell contains one positive and two negative plates. The united elements constitute a battery of a mean voltage of 3.9, sufficient to supply, for 15 consecutive hours, a small incandescent lamp with a constant illuminating power of about one candle. In order to avoid the spilling of the liquid, the electrolyte of the accumulators is "fixed by a special process," in such a way that the lamp may be used without risk in any position whatever. The protecting globe is painted to one-half with a semi-translucent white varnish which acts as a reflector, while allowing a certain amount of light to be diffused backward. A lamp giving 1 cp for 15 hours weighs five pounds. It consumes 3.5 watts per candle-power. To recharge the lamps a charging table, consisting of 20 or 40 compartments is used, according as the available e.m.f. is 110 or 220 volts.—Lond. *Elec. Rev.*, April 22.

Three-Phase Arcs.—An illustrated account of the experiments of Mercanton on this subject.—*Scientific American*, May 7.

POWER.

Power Station Design.—MERZ AND MCCLELLAN.—The first part of a paper read before the British Institute of Electrical Engineers. The authors think that since the early days of the distribution of electrical energy, an amount of attention has been directed to the power station as compared with the distribution system which is hardly warranted by its importance from either an engineering or commercial standpoint. The expenditure upon the distribution system is probably, in the majority of cases, more than 50 per cent. of that on the whole scheme, especially if the consumer's installation be taken into account. The distribution system has a comparatively high efficiency, probably not less than 75 per cent. On the other hand, the power station has a comparatively low efficiency, not more than 10 per cent.; there is thus room for large improvements in the generation of power. For this reason the depreciation accounts must necessarily form a much higher percentage of the capital cost than in the cost of the distribution system. A power station is capable of easy extension without effecting in a very marked degree the ultimate cost; it can, therefore, be begun on a smaller scale. It may pay in future to change even the location of the station. The authors suggest that 10 per cent. per year should be considered as sinking fund in deciding whether to spend more money than is absolutely necessary on any particular section of the plant in a power station in order to secure lower running costs. The relative importance of capital costs and running cost may be seen at a glance for any particular values of either load factor, capital cost or running cost from the curves shown in Fig. 2. It will be seen that a reduction of the capital outlay by £1 (about $5) per kw has a greater effect on the running cost than has a reduction of the coal bill by 6 per cent. This applies with a load factor as high as 30 per cent.; it is, therefore, evident that for lower load factors the question of limiting capital expenditure becomes of overwhelming importance as compared with that of reducing running cost. The authors emphasize the importance of simplicity of design and recommend to subdivide all parts of the plant and apparatus, from the boiler house to the switchboard, into a series of units each complete in itself. Labor-saving devices are becoming more and more desirable, but their installation should be carefully considered. On the one side should be put capital charges, taken at not less than 15 per cent. of the capital cost and repairs, the latter to be estimated. On the other side should be put the saving in labor. Provision should always be made for extensions. The authors then discuss the actual design of a plant generating three-phase, high-tension currents at 5,000 volts or more. They first deal with the type of generating plant. High-speed reciprocating engines cost for the same power less than those of low speed, and will take up less room. On the other hand, the advocates of low-speed engines claim that the repair bill of a high-speed engine is higher and the economy not so good. The authors speak very favorably of steam turbines and give the results of tests of a 2,000-kw Parsons steam turbine which was installed at Wallsend in 1901. This turbine was run 7,500 hours without ever having been opened up, and only on two occasions have the bearings needed any resetting in order to keep the clearance correct, although

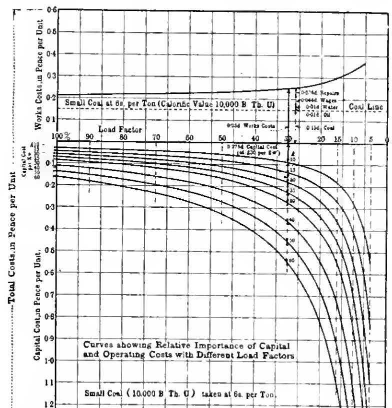

FIG. 2.—CURVES SHOWING COSTS.

they were three times examined and the clearance tested. The only faults of any kind which it has been necessary to repair have been the relining of one of the governor throttle valve chests and the renewal of an oil disc. "Steam turbines seem in every respect to be specially suitable for power scheme purposes, and, although they have taken many years to develop, it is probable that, had there been a demand 10 years ago for 2,000-kw generating sets, turbo-alternators would have been the only large-size generating units in extensive use at the present day." The authors prefer steam turbines to gas engines and draw the balance sheet as follows: Gas engines—Low coal bill, high oil cost, high labor cost, high repair cost; and, most important of all, high capital cost. Steam turbines—Low oil cost, low labor cost, low repair cost; and, most important of all, low capital cost. In the coal bill there is a slight difference in favor of the gas engine. The authors then discuss the general arrangement of a central station. They recommend that the auxiliary buildings, repair shops, stores and all sidings should be put down before the buildings are started. With regard to the general layout of the main buildings, the modern station is tending towards what may be called the complete unit system. For a large power station this tendency might with advantage be carried further than is the general practice at present, so that the only junction between the various units will be: First, at the railway siding or other source of coal supply; second, at the river or other source of circulating water supply; third, at the main bus-bars. In fact, a large power station might with advantage be so designed that the boiler house plant, the steam piping system, the generating system and the switchboard may all be entirely subdivided into different units.—Lond. *Elec.*, April 29.

Belgian Colliery.—A description of the electric installation of a Belgian colliery. A 250-kw generator furnishes three-phase currents at 1,000 volts. More than 75 per cent. of the output of the machine is used for running a winding engine installed underground at a depth of 525 meters. The motor runs at 415 r.p.m. with a normal output of 125 hp, the maximum torque developed under certain working conditions corresponding to 300 hp. It is an induction motor with the slip rings placed outside o fthe bearings in a gas-tight box and is fitted with power and electric brakes, and can also be braked by means of a counter weight, which cuts the motor circuit. The machine is also equipped with an electric device to keep the cage clear of the sheaves, and a side indicator. The balance of the energy is used for pumping and lighting.—*Mines & Minerals*, May; from *Colliery Guardian*, January 29.

Coal Mining.—HARRIS.—An illustrated description of the Ernest plant of the Jefferson and Clearfield Coal & Iron Company, at Ernest, Pa. The electric equipment consists of two multiphase 300-kw, 575-volt generators. Electric power is used mainly for haulage. There are provided ten 10-ton and one 20-ton, 500-volt mining locomotives. Each of the 10-ton locomotives has a cable extended so that two may be coupled together electrically. This arrangement gives many of the advantages of the 20-ton locomotive and permits a 10-ton locomotive to be used separately when one of them will do the work. Traction advantages are also claimed for the combination over the single 20-ton locomotive.—*Mines & Minerals*, May.

TRACTION.

Direct-Current Versus Single-Phase for Traction.—HOBART.—The first part of an article in which the author points out that it is unreasonable to disregard the undeveloped possibilities of the direct-current motor, especially in the matter of operation at higher voltages, in connection with traction. The author does not deny the possibilities of a single-phase system for main line work, but points out that, contrary to expectations, it is not so much for main line work, but more especially for urban, suburban and interurban work that the single-phase motor is at present strongly advocated. Compared with the direct-current motor, the single-phase motor has a larger commutator, greater commutator losses, no better commutation, a higher voltage per turn in the field spools (with increased danger due to a break-down in the insulation), larger internal losses and smaller efficiency; moreover, the power factor of the single-phase commutator motor falls considerably short of unity for all excepting a very narrow range of loads; and with this system considerable auxiliary apparatus is required on the car. The author then criticises Lincoln's comparison of alternating versus direct current for interurban traction systems (ELECTRICAL WORLD AND ENGINEER, December 3, 1903), and points out that in this comparison for a 60-mile interurban line, 600 volts is taken for the direct-current system and the cost for the secondary network amounting to 30 per cent. of the total cost of the electrical system is deduced. "In fact, it is only by comparing a 3,000-volt secondary network for the single-phase system with a 600-volt network for the continuous-current system that an advantage appears to be obtained for the single-phase system." The author offers the following criticisms of Lincoln's estimate: that it is overlooked that single-phase generators cost some 30 per cent. more than polyphase generators for the same rating and guarantees; that the increased cost of low frequency transformers is overlooked; that there is no reason to use many small and expensive single-phase transformers for the polyphase central and sub-stations (although this has been formerly the practice in the United States); that the single-phase generating plant is not sufficiently liberally proportioned, in view of the average power factor; that since the chief handicap of the direct-current system is the low-tension, the voltage should have been increased, as this is a perfectly sound proposition in the present state of the art; that large transformers are artificially cooled and some attendance is advisable even for single-phase sub-stations. The high voltage per turn in the field spools of the alternating-current systems, the less satisfactory commutation and the more complex auxiliary apparatus will inevitably result in a higher percentage depreciation than for the direct-current equipment; nevertheless, Lincoln takes 10 per cent. for the former and 12 per cent. for the latter. The article is to be concluded.—Lond. *Elec. Rev.*, April 29.

Tramcar Control.—An illustrated description of a regenerating system of tramcar control, devised by Raworth. The article is based on two recent English patents. The first patent refers to the regulation of shunt-wound motors by means of controlling both the field circuit so that the armature circuit cannot be made or broken until the field is excited to a maximum. The second patent refers to the return of energy to the line when the car descends a gradient. The motors are compound-wound and the series windings are arranged to strengthen the field when the armatures are returning energy, and, therefore, to weaken the field when the motors are receiving energy from the line. In starting the car, the series field winding is short-circuited and has no effect on the field. To increase the speed the driver pushes the speed lever and the braking handle moves with it, the shunt field being reduced by the insertion of resistance. If the speed increases too much, he draws back the speed lever, thereby removing resistance and strengthening the field. In descending steep hills, the driver first draws back the speed lever until the increased strength of the field returns a strong current to the line, and then, if more retarding effort is required, he pulls back the braking lever, the effect of which is to remove the short-circuit of the series winding and to still further strengthen the field. The controller may be so arranged that in case of emergency, for instance, the trolley leaving the line, further motion of the lever and handle will short-circuit the armature through the series winding, thus bringing the car to a stop or nearly so. No other brakes are necessary than the hand brake to hold the vehicle when stopped; but should the trolley leave the trolley wire, then, unless additional braking means are provided, there is great liability of a serious accident taking place. Means are, therefore, provided to let the motor then act as generators and also as a very powerful brake. All the arrangements are described in detail and illustrated.—Lond. *Elec.*, April 29.

Germany.—An article on the financial results of electric railway operation in Germany. Electric traction has proved there much more costly than was anticipated when electrification was inaugurated, this increase being due chiefly to the higher charges for power, maintenance of track and rolling stock, wages, accident costs and pavement repairs. The only favorable factor which has enabled most of the companies to continue on a paying basis has been the unexpected increase in traffic. The fever for municipalization has abated in view of the results attained on most of the municipal lines as compared with private ones under similar conditions.—*St. R'y Jour.*, May 7.

REFERENCES.

Three-Phase Traction.—KANDO.—In the continuation of his polemics with Lalino he emphasizes that the operation of the Valtellina road has completely proven the practicability of braking with the cascade system and the possibility of winning back energy when running down hill, so that with a road for which saving of energy is of important value reliance can be placed on the above two factors.—*Elek. Zeit.*, April 28.

Noiseless Fuse.—An editorial on the use of a noiseless fuse on large cars, especially elevated railway cars, where a panic may be produced by the burning of the ordinary fuse. It is thought that the fuse could be encased in a porcelain enameled steel shell with a muffler at each end.—*St. R'y Jour.*, April 23.

WIRES, WIRING AND CONDUITS.

Inductive Voltage Drop in Three-Phase Lines.—LICHTENSTEIN.—The first part of an illustrated article referring to some errors which may occur in connection with voltage measurements of a three-phase line. He has found in practice that in an auxiliary wire used for measuring purposes, voltages may be induced even if the distance of this auxiliary wire from the three main wires is relatively very large. He also found that the formula for calculating the inductive voltage drop of parallel alternating-current conductors is no longer valid for three-phase lines, and that the inductive voltage drop must be specially calculated in each case. He gives the mathematical theory of the subject and shows conclusively that in the auxiliary wire voltages are induced of such magnitude that they may influence the result considerably. If the three wires for the three-phase system are in one plane (as is generally the case in three-phase traction installations) he shows that in the auxiliary wire voltages are always induced whatever may be the distance from the three main wires, for instance if this distance is even greater than 8 meters. The article is to be concluded.—*Zeit. f. Elek.* (Vienna), April 24.

REFERENCE.

Eddy Currents in Cable Sheaths.—FIELD.—Two mathematical supplements to his paper abstracted recently in the Digest. In the first he discusses the distribution of induction and eddy currents in a long iron pipe, enclosing an alternating current. In the second the magnetic fields due to various systems of straight parallel conductors are considered, it being assumed that the conductors are circular in section and that the distribution of current over the cross-section of each conductor is a function of the distance from the axis of the conductor only.—Lond. *Elec.,* April 29.

ELECTRO-PHYSICS AND MAGNETISM.

Electric Origin of Rigidity.—SUTHERLAND.—A highly theoretical paper on "the electric origin of rigidity and consequences." The author endeavors to substitute the "doublet theory" for the electron theory, a doublet being a combination of two oppositely charged electrons. The chief difference which the doublet theory of valency makes when substituted for the electron theory is that for over doublet which the electron theory would require on account of the attraction of opposite electrons the doublet introduced an inner doublet whose electrons are very close together. In his theory the most important characteristic of the molecules in metals is that each atom contains in itself both a positive and negative electron. Rigidity at absolute zero is a purely electrostatic affair, but its variation with temperature is a simple kinetic phenomenon. The electric doublet forces the material atom to vibrate. The combined existence of electrostatic and electrokinetic energies in the same pair of electrons is conceived by imagining the electrons to travel over the surface of the atom in curves similar to screws having a small pitch, so that the motion parallel to the axis of the screw negligible in comparison with that around it. The average distance along the axis of the screw between the two electrons is the distance, s, which gives the pair of electrons the electric moment, $e\,s$. The electrokinetic energy of motion round the axis and the electrostatic energy due to separation of charges along the axis, may both be regarded as a store of energy. Since the pair of electrons in an atom of metal possesses electrokinetic energy by virtue of the rotation of the electrons around an electric axis it must have gyrostatic properties. Each atom is equipped with an electrostatic doublet and an electrical gyrostat, both having the same axis. In the metallic conductor all the gyrostats vibrate in a field of electric force, like a number of spinning tops in the field of gravity. The monatomic atom of a metal with its doublet he calls a stion. Metallic conduction is due to the dissociation of stions, electrolytic conduction to the dissociation of molecules. In metallic conduction there is a breaking of molecular gyrostats and the flying together of the broken pieces. The author discusses at some length the consequences to which his theory leads concerning electrical and thermal conductivity in metals. He then deals with the contact difference of potential and the mechanism of the storage of potential chemical energy in the ether. He finally uses the neutron structure of the ether for the calculation of its density and rigidity and the deduction of the velocity of light. The author distinguishes three distinct ways in which kinetic energy can exist in the ether; first by rotation of an electron round its center, connected with magnetic permeability of the ether; second, by rotation of neutron, which is the same as translation of electron; and third by motion impressed on the doublets of matter by the atoms, this being the origin of radiation.—*Phil. Mag.,* May.

N-Rays.—COLSON AND MEYER.—Two French Academy papers on this subject. Colson is of the opinion that the N-rays are capable of being utilized as a delicate chemical reagent of considerable value. Some chemical reactions are the source of N-rays, while other and very similar ones are not. In preparing zinc hydrate the result is the same whether zinc sulphate is added to caustic potash solution or the latter is added to the former. But in the latter case, the reaction gives rise to N-rays, which diminish the brightness of a phosphorescent screen, whereas the reverse process does not give rise to the rays. This evolution of rays is accompanied by the formation of a basic salt which is only formed as long as the zinc sulphate is in large excess. Calorimetric tests show that the formation of this basic salt gives rise to a greater quantity of heat than the formation of the zinc hydrate without such an intermediary stage. Meyer has discovered some new sources of the extinguishing rays called by Blondlot N-rays, and has obtained rays of a higher penetrating power than heretofore. If a screen with patches of phosphorescent calcium sulphide is placed in the receiver of an air pump and the pump is worked, the prosphorescence decreases, being restored as soon as the pressure is restored. The same thing happens if the screen is placed outside instead of inside the receiver. An incandescent lamp through which no current passes, or a vacuum tube, are powerful sources of N-rays, the strain of the glass under atmospheric pressure being sufficient to account for their production. —*Comptes Rendus,* April 11; Lond. *Elec.,* April 29.

ELECTRO-CHEMISTRY AND BATTERIES.

Formation of Hydrogen and Oxygen Gases by Alternating Currents.—VAN NAME AND GRAEFENBERG.—An account of an experimental investigation in which the output of formation of hydrogen and oxygen gases by alternating currents and the voltages applied were measured with platinum and gold electrodes in sulphuric acid and with silver, nickel and copper electrodes, in potassium hydrate. The frequency was held constant at 55 periods per second and the current density was varied. The largest efficiencies obtained were only about one-half of that which can be obtained with direct current. Moreover, these efficiencies could be maintained only for a limited time on account of the electrodes being attacked. Concerning their suitability as electrodes, a number of substances were examined, but no entirely satisfactory substance was found.—*Zeit. f. Elektrochemie,* April 29.

REFERENCES.

Calomel Electrode.—LEY AND HEIMBUCHER.—An account of an experimental investigation on the concentration of the mercury ions in the calomel electrode and on the solubility of calomel. For the concentration of the mercury ions in the 0.1 calomel electrode, and in the .1 normal calomel electrode they find the values 2×10^{-16} and 3.5×10^{-18}, respectively.—*Zeit. f. Elektrochemie,* April 29.

Influence of Light upon the Formation of Lead Accumulators.—SCHOOP.—A note with reference to a recent article of Tommasi, whose results he confirms. He describes the following experiments: A peroxide lead plate, formed according to Planté, was cut into three parts, of which one was left in the dark, the second in the daylight, and the third was placed in the direct rays of the sun. The color of the latter two changed appreciably after some hours.—*L'Eclairage Elec.,* April 30.

UNITS, MEASUREMENTS AND INSTRUMENTS.

Measuring Small Inductances and Capacities.—FLEMING.—A description of a convenient method for measuring small inductances. The arrangement is illustrated in Fig. 3. The inductance, L, is

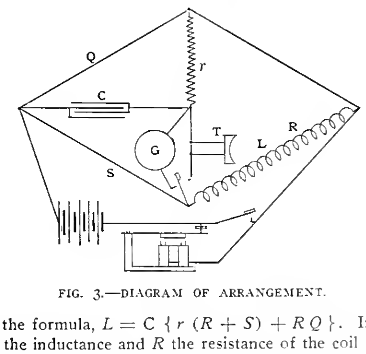

FIG. 3.—DIAGRAM OF ARRANGEMENT.

given by the formula, $L = C \{ r (R + S) + R Q \}$. In this equation L is the inductance and R the resistance of the coil being measured, C the capacity of the condenser consisting of one or more Leyden jars (or a mica condenser), S and Q are the resistances of the adjacent and opposite bridge arms, and r is the resistance inserted in series with the telephone in the bridge circuit, a resistance box being used for r. The steady balance is first obtained in the usual way with the galvanometer and steady current. If the telephone, T, is substituted for the galvanometer and an ordinary buzzer is used in the battery circuit to interrupt the current at the rate of about 100 per second, and when r is adjusted to produce silence in the telephone it was found that variations to the extent of about one per cent. either way and sometimes much less caused the sound to reappear in the telephone. The author has found that solenoid coils constructed by winding silk-covered copper wires in one layer and in closely adjacent turns on a glass rod, have an inductance which is very nearly equal to the length of wire per unit length of solenoid multiplied by the total length of wire used to form the solenoid. This rule is correct as long as the length of the solenoid is at least 50 times that of the diameter. The above arrangement may also be used to determine the capacity in the bridge, assuming the value of the inductance calculated from this formula. On the basis of this formula he describes a method for the calibration of a variable inductance for use for certain resonance experiments.—*Phil. Mag.*, May.

REFERENCES.

Measuring Conductivity of Wires.—Appleyard.—A description of his conductometer, which is a direct-reading instrument intended for the comparison for electric conductivity of copper and other wires, for a range within, say, 5 per cent. above and 5 per cent. below 100.—*Phil. Mag.*, March.

Rymer-Jones.—The first part of an article in which the author doubts the advantages of the conductometer over the simple meter bridge.—Lond. *Elec. Rev.*, April 29.

Meters.—A description of the following meters which have been accepted for calibration by the German Reichsanstalt: A direct-current motor meter, a single-phase induction meter and a three-phase induction meter, all made by the Union Electric Company, of Berlin. The construction and method of calibration of the instruments are described in detail and exact drawings are given.—*Elek. Zeit.*, April 28.

Hot-Wire Ammeter.—Fleming.—An illustrated description of a hot-wire ammeter for the measurement of very small alternating currents. Currents as small as two milliamperes can be measured and the instrument can essily be calibrated at the time of using it. As an instance of the application of the instrument he gives the measurement of the magnetizing currents of small transformers.—*Phil. Mag.*, May.

MISCELLANEOUS.

Lightning Rods.—Kirstein.—An article urging the erection of lightning rods on buildings in rural districts. Care should be taken to examine them regularly concerning their efficiency.—*Elek. Anz.*, April 28.

Asbestos.—An illustrated article on the equipment of the works of the United Asbestos Company with a general description of the methods of mining and treating asbestos and of its various uses.—Lond. *Elec. Rev.*, April 29.

New Books.

Congres de la Houille Blanche. Grenoble, France: Syndicat des Forces Hydrauliques, Chambre de Commerce. 2 vols. 1,270 pages, illustrated. Price, 30 francs; with foreign postage, 31 francs 50 centimes.

These massive and handsome volumes are devoted to a record of the remarkable Congress held at Grenoble in September, 1902, to develop the subject of the utilization of water powers in general, of those of France particularly, and peculiarly those of the region in which the congress was held. As the readers of this paper know, the French describe water power in a happy phrase as "white coal," or "houille blanche," and it will also be remembered that at the time of the meeting a large amount of space was devoted in these pages to a report of the work done. We find here, however, all the papers in full and a verbatim record of the discussions. Even this does not convey the full meaning and importance of the affair, for the men who participated while not all of them known personally or by name in America, were Frenchmen of distinction, of talent and genius; and their work in this convention was done with a skill and thoroughness that must evoke intense admiration wherever it is studied.

The first volume is devoted to the papers and discussions, all, as we have intimated, of an admirable quality and high order of merit, dealing not alone with engineering aspects of the question, but with legal, industrial, commercial, social, each handling its topic with characteristic French sanity and lucidity and compelling one to stop and read at almost every page. The second volume takes the theory of the first volume and shows how it has all actually been worked out in practice in that splendid water power region of Haute Savoie, which, running south from Bellegarde, finds Grenoble as its center. What has been done there is exemplified in hundreds of cuts, accompanying the description of the trips which were undertaken by members of the Congress. In short, the student of water power development who has these volumes at his elbow is fortunate, and without them he is far from being fully acquainted with his subject. It may be added that the utilizations are quite largely electric—lighting, trolleys, power service, electrochemistry, etc.

Electrical Engineering Experiments and Tests on Direct-Current Machinery. By George F. Sever. New York: D. Van Nostrand Company. 64 pages, 22 illustrations. Price, $1.00.

This is a compilation of tests on direct-current machinery, primarily adapted for the direction of third-year students in the shorter laboratory courses of electrical engineering at Columbia University; and secondarily for those who may, in the practice of electrical engineering, desire a synopsis of the simpler tests on direct-current dynamo machinery.

A series of experiments is detailed in the book. These are: (1) The measurement of fall of potential along a wire. (2) The measurement of resistance by fall of potential. (3) The measurement of higher resistances by Wheatstone bridge. (4) The operation and tests of a shunt-wound constant-potential dynamo. (5) The operation and tests of a compound-wound dynamo. (6) The operation and tests of a shunt motor. (7) The operation and tests of a series motor. (8) Tests of a dynamo or motor by the stray-power method. (9) Operation of shunt dynamos in parallel. (10) Operation of compound dynamos in parallel. (11) The operation of a constant-current dynamo, and of arc lamps.

These experiments are clearly defined and described. The diagrams of connections are given, and also tabular forms for recording the observations.

The pamphlet will be of distinct value to students of electrical engineering not only in college, but also wherever direct-current machines have to be operated and tested. The treatment is in conformity with the standardization rules of the American Institute of Electrical Engineers and the notation is in the international system.

A Self-Cohering Receiver.

By Edward Van Winkle.

It is doubtless true that no one at present engaged in the wireless business is entirely satisfied with the results obtained; and the indifferent success has been charged, by a great majority of the wireless people, to the inefficiency of the initial spark as employed in the past, and they have looked for the solution of this fault in the stepping up of the initial spark, with the hope of improving the signal received. In analyzing, however, the defects of instruments as they become apparent through application and use, a radically different view of the remedy required to produce clear signals, has been proposed, the position being that the initial energy of the spark was sufficient, but that the energy contained in the impulse was lost in the faulty construction of every known wireless receiver; that the imperfect signals received were due to the fact that all wireless receivers had their local circuits legged off the antenna and ground wire, thus bridging across the fluctuating point in the receiving instrument and providing a circuit around the fluctuating point instead of through it; and as these local circuits carried less resistance than any known coherer, or anything else used as a fluctuating point in wireless receivers, a great proportion of the impulse assembled on the antenna passed around the fluctuating point while passing to the earth and was lost. Here lay the reason for the indifferent success, and a solution was, not to step-up the initial spark, but to insulate the wave circuit from the local circuit and prevent a loss of the wave energy after contact with the vertical wire.

This principal is applied on the Peters self-cohering receiver, to which the accompanying illustrations refer. In this the local circuits are entirely insulated from the wave circuit, and yet be capable of duplicating in the local circuit the electrical phenomena constantly taking place in the wave circuit as the impulses pass through it to the earth. On several occasions controllable signals have been received over a distance of three miles using only the spark of a single "Mesco" dry cell.

Referring to the illustrations, Fig. 1 is a diagramatic sketch of the receiver, Figs. 2 and 3 sections of the coherer, and Fig. 4 is a photographic view of the coherer, motor-driven, with a regular Morse sounder on the right; the ground wire is shown in foreground.

The coherer includes two electromagnets 1, placed in reverse with

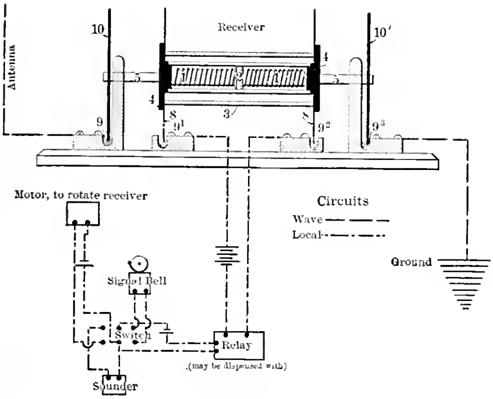

FIG. 1.—DIAGRAM OF CIRCUITS.

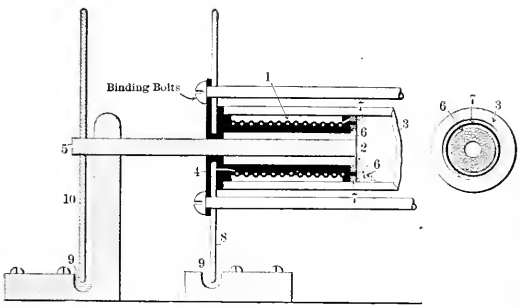
the filing-gap 2, between their ends in a glass tube 3, sealed by insulating end plates 4. Both electromagnets have for a core the shaft 5, around which are placed a number of soft iron wires secured at the gap end by a ring of soft iron 6, which is insulated from the soft iron ring 7. This latter ring is the terminal of the coil at the gap end, the other terminal of the coil being the discs 8. The wall of the filing gap is formed of the ends of the core and the insulated terminal ring of the coil, all of which is clearly shown in the illustration.

The coherer is rotated by the motor shown diagramatically. The shaft of the coherer on the left is connected to the antenna, or vertical wire, through the mercury well 9, and the disc 10. The other shaft is connected to the earth through the mercury well 9^3 and the disc 10^1. The coils of the electromagnet are in relay or local circuit through the discs 8 and 8^1.

The bell is in circuit when the switch is thrown to the right, and



FIGS. 2 AND 3.—SECTIONS OF COHERER.

is used only to notify the operator that a message is about to be received. As soon as the filings are magnetized the bell circuit is closed through the batteries and relay, and the bell rings. The operator then throws the switch to the left, which throws both the sounder and the coherer motor in circuit; the coherer then revolves and is ready for message. The iron filings in the gap between the ends of the electromagnet should fill about one-third of the gap, or sufficient to lap the core and coil terminals at all times. When the receivers is in motion the filings as a mass are carried around with the tube, until raised above the angle of repose, when they break away at the top and falling over themselves, reform again at the bottom to be carried up again in endless repetition; this being the decohering process constantly maintained by the rotation of the tube. It will also be noticed that between the top of the mass where the filings break away, and the bottom where they reform, is an area of filings never disturbed with respect to their contact with the walls of the gap (coil terminals); this mass of undisturbed filings is always ready to be cohered when a wave of very high potential passes through, notwithstanding their continuous rotation.

No other type of coherer gives as clear a signal as a filings coherer, and its defect of lack of speed owing to the filings requiring to be tapped is overcome by decohesion secured through rotation. The sensitiveness of this coherer is evident from the fact with the usual filing mixture, 90 per cent. of nickel and 10 per cent. of silver filings it would cohere toó thoroughly to permit of decohesion under the influence of the electromagnetic coils; this compels the use of ordinary iron filings mixed with 40 per cent. of brass filings in order to introduce in the mass a non-magnetizable metallic weight as a roving element in the mass, to break down the perfect state of cohesion maintained by the coils.

The fluctuating point in the local circuit is established by placing sufficient filings in the gap. The wave or impulses entering through the core of the electromagnet coheres the particles and closes the local circuit, the effect of which is to assist or increase the cohering action by energizing the cores.

The cores of the electromagnets constitute the wave circuit and the coils the local circuit, thus completely insulating them, and leaving the local circuit free to energize the cores of the coils when the impulses cause the local battery to flow, by magnetizing the filings that lay between the terminals of the two coils. In this way the local battery is utilized to assist in perfecting cohesion, the wave in the instrument being utilized only as a trigger to start the local batteries to flow, which by their local action complete the act of cohesion.

The mercury wells shown in the diagram, and the wheels rotating therein, are for the purpose of making continuous contact between the movable and stationary parts of the instrument; commutator contacts will be employed in the future construction of the instrument to accomplish this purpose.

The change of potential in this receiver is equal to the actual opening and closing of a circuit, thus giving variation of current sufficient to operate an ordinary set of Morse telegraph instruments giving audible signals, clear enough to be received and copied while operating a typewriter.

The advantages claimed for this device over all others are:

1. Its absolute simplicity. 2. It requires no adjusting after being correctly constructed. 3. Any number of instruments can be operated on the same antenna. 4. It will enable a receiving station to break a sending station. 5. An operator can read the message that he is sending off his receiving instrument. 6. The instrument will receive a wireless message and repeat it to a telegraph line, and vice versa. 7. The filings being always in position for action, and no time being lost waiting for their recovery, a much greater speed can be secured than with a coherer in which the filings are scattered

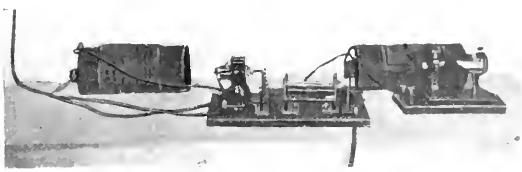


FIG. 4.—VIEW OF MOTOR-DRIVEN COHERER.

by tapping or dumping. 8. Owing to the assistance given the waves by the electromagnetic coils in cohering the filings, a message can be received at greater distances and from weaker signals than by other instruments. 9. The wave and the local circuits being insulated from each other, no part of the impulse is lost through the legged or local circuits. 10. As the entire mass of filings is decohered by one-tenth of a revolution of the tube, and as the tube decoherer is safely under eight revolutions per second, the make and break of the circuit can occur eighty times per second. 11. This coherer is capable of changing the resistance in its gap practically equal to the absolute opening and closing of the circuit.

High-Voltage Oil Switches.

The oil switches shown in the accompanying illustrations, made by the Stanley Electric Manufacturing Company, are so designed that the circuit is broken simultaneously at several points, thus distributing the resulting disturbance over a considerable area. Moreover, for potentials above 6,600 the various contacts are arranged in the same horizontal plane, so that the disturbances resulting from the rupturing of the arc are distributed, rather than concentrated, as is the case where the contacts are one below the other. Another advantage of opening the contacts in a horizontal plane is that the arc tends to flare upwards, increasing its length and thereby securing a longer break than in the vertical type, with the same separation of contacts. The contacts are located comparatively near the surface of the oil, so that the gases resulting from the explosion are readily dissipated, and, by using comparatively large tanks and long breaks, the switch may be opened and closed many times before the oil is carbonized appreciably.

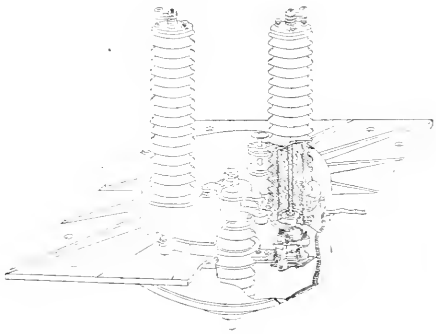

FIG. 1.—60,000-VOLT OIL SWITCH.

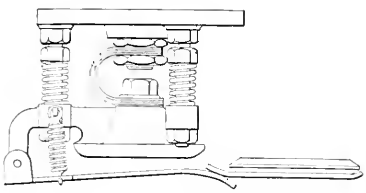

FIG. 2.—CONTACT OF 60,000-VOLT OIL SWITCH.

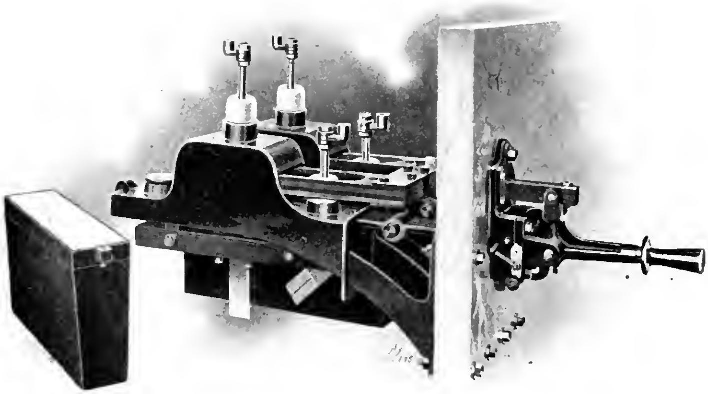

FIG. 3.—3,500-VOLT OIL SWITCH.

The principles of construction above outlined are embodied in a 300-amp., 60,000-volt switch, a number of which have been installed as a part of the equipment of the high-voltage transmission systems in the West. Fig. 1 gives an idea of the general construction of the switch. Each pole consists of, first, a cast-iron top or mounting plate, on which are mounted the two terminal contact insulators, a bearing of liberal length for the driving shaft, and a combined gas vent and automatic oil level indicator; and, secondly, a tank filled with oil in which are immersed the contacts suitably insulated. The insulators are of porcelain made in the form of corrugated cylinders. The center insulator carrying the contact blades is entirely immersed in oil. The two terminal insulators are partly filled with and have their lower ends immersed in oil. These two insulators are held in position by means of hollow clamp rings, which are fastened to the insulators with set-screws and cement. The contact blades are fastened to the central insulator in a similar fashion.

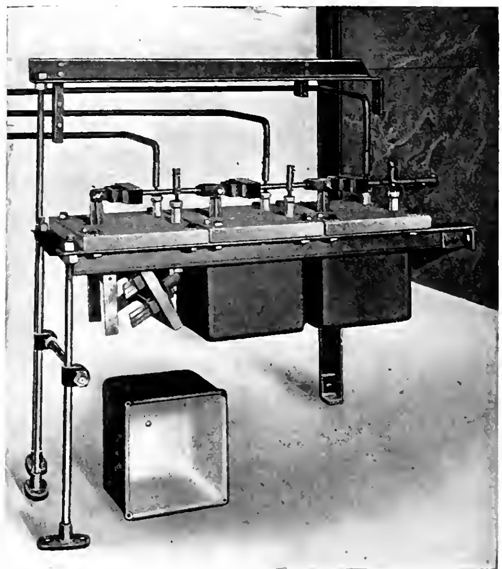

FIG. 4.—6,600-VOLT, THREE-POLE SWITCH.

Fig. 2 shows the details of a contact. The contact arms are of hard-drawn flat copper strips. Each fixed contact is forced downward by three coiled springs which are carried on the studs on which the fixed contacts slide, and which are screwed on the battom of the insulator. These fixed contacts, as well as the blades, have ground surfaces. On closing the switch, each contact blade slides under the corresponding fixed contact, and, owing to the arrangement of the springs, a perfect self-aligned contact results.

The shape and position of the shunt or arc-rupturing contacts are such as to prevent any possibility of the arc being taken by the main contacts. These auxiliary contacts are readily replaceable. In the illustration, the oil level indicator can be seen on the left of the insulator, the construction of which is exposed. Should the oil leak out, or, for any other reason, recede below a safe level, the indicator closes the pilot circuit and warns the attendant by ringing a bell or lighting a lamp, as may be desired.

Each switch is tested at 120,000 volts and, in installing, the iron top and tanks are grounded, making it perfectly safe for the operator to handle the controlling device. The three-pole switch is made up of three of the units described above, connected by rods and the crank on each operating shaft to either a motor, magnet or hand-operated controlling device, and the operation of either of these devices may be controlled by plain overload, time delay overload or reversed current relays. Each pole of the switch may be mounted in either soapstone or brick compartment or upon iron framework.

Fig. 4 shows a three-pole oil switch for voltages up to 6,600, and for currents up to 100 amp. Each pole is in a separate tank, as is the standing practice for oil switches for potentials exceeding 3,000 volts. The tanks are mounted in a strong, yet light framework consisting of angle irons and rods. This switch is made with circuit-breaker attachment, if so desired, and either single or double-throw. One tank can be used as a double-pole switch with a capacity of 100 amp. at 2,400 volts, by connecting one blade to each pole. By connecting the blades in parallel, instead of in series, the switch may be used for 200 amp. at 4,000 volts. It is thus evident that this type of switch is readily adapted to meet a wide range of conditions.

Fig. 3 shows an oil switch designed for installations of not over 3,500 volts. It is made either single or double-throw and for any number of poles desired. The normal three-phase capacity of the switch is 400 kw and the emergency three-phase capacity is 1,200 kw: in other words, these switches should not be installed on circuits which have more than 400 kw normal capacity back of them.

The switch is also made with an automatic overload opening device When so furnished, the handle for closing the switch is not connected rigidly to the parts making contact, but is latched thereto, the arrangement being such that it is impossible to close the switch when there is an overload or short-circuit on the line. With this overload feature, series transformers are used, but one being necessary for either a single-pole or two-pole switch and two for either a three-pole or four-pole switch. As in the switches for higher voltages, there is a separate tank for each pole.

Silvered Mica Condensers.

For the benefit of those familiar with the construction of ordinary condensers it may be well to say a word about these before explaining the silvered mica condenser. In the ordinary condensers made of mica and tin-foil, the air between the surface of the tin-foil and the dielectric causes a variation in the capacity of the condenser, and if

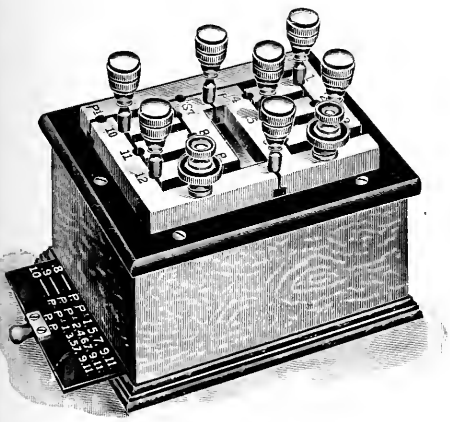

FIG. 1.—ADJUSTABLE CONDENSER.

they are used on alternating-current circuits or subjected to inductive discharges, what might be called electrostatic bombardment will heat them to such an extent that they are liable to break down.

In the silvered mica condenser, these conditions as well as many others are overcome in a most marked degree. This condenser is made by depositing silver on mica. Figs. 1, 2 and 3 show forms of these condensers as manufactured by Messrs. Glifford H. Brown & Co., of New York City. Fig. 1 shows diagram of a 1-m.f. series-multiple and multiple-series standard condenser. It consists of ten 1/10 of a m.f. condensers. It will be seen from the diagram that these condensers may be used singly, in series, multiple, series-multiple and multiple-series, making many combinations possible. In the position in which the plugs are shown, two condensers are in

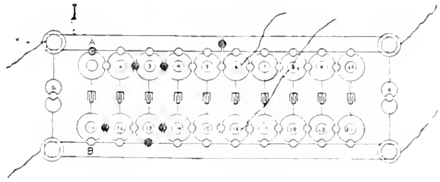

FIG. 2.—DIAGRAM OF CONDENSER CONNECTIONS.

series with two in multiple giving a capacity of .04 m.f. The range of this condenser is from 1 m.f. to 1/100 of a m.f.

Fig. 1 shows an adjustable 1-m.f. standard condenser, the minimum capacity being .025 m.f. This condenser is provided with a printed card, which slides in and out of the bottom of the box. On this card are marked the numbers of the plug holes to obtain the desired capacity. This card will be found of great convenience as well as a time saver.

Fig. 3 shows a non-adjustable standard condenser designed for high potential work. We are informed that Dr. Pupin is using a

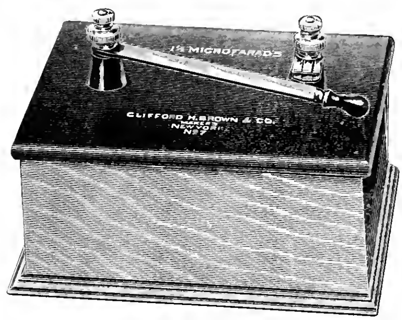

FIG. 3.—NON-ADJUSTABLE CONDENSER.

number of these condensers in connection with multiple telegraphy. These condensers are not only of value as standard, as above indicated, but may be used on high-potential alternating circuits without heating or changing capacity.

Water Power in France.

Mr. H. S. Brunot, United States Consul at St. Etienne, France, in a recently communicated report, says: "Besides the new water supply from the Lignon and electric power works belonging to the municipality of St. Etienne, which are now being constructed, there is another project being studied as a private enterprise which concerns the distribution of electric power and light not only to St. Etienne, but to all the principal towns of the Department of the Loire. M. Mallet, civil engineer at St. Etienne, is the promoter of this scheme and has great hopes of seeing it realized. The water will be taken from high up in the Department of the Ardèche, the source being a small lake 1½ miles in diameter. Certain dams and embankments will be constructed to increase the reservoir capacity of this lake, so as to guarantee a constant supply. The energy expected to be derived is calculated at 20,000 hp. All the industries of the region will benefit by these undertakings. Authorization to commence operations has been applied for from the French Chamber, and if the necessary sanction is given the use of electricity will be largely substituted for steam in this part of the country."

Western Electric Company's New Plant.

The Falkenau Construction Company has been awarded the contract for the erection of some more new buildings at the Western Electric Company's plant at Hawthorne, near Chicago. The principal building will be for the insulating plant and will be 401 x 200 ft. The total cost, with other lesser structures, will be about $142,000.

Lighting by Cooper Hewitt Lamps.

One of the novel fields of electric lighting which has seen the most rapid development since the National Electric Light Association met a year ago is that of vacuum tube work. A great deal more has been done in this department that is realized by the electrical public, while some of the installations are of a character to excite surprise even on the part of those who are well informed. As an example of the extent to which the mercury vapor lamp has been introduced, we illustrate herewith the battery room of the New York Transportation Company, on Forty-ninth Street and Eighth Avenue, New York City. This corporation operates the hundreds of electric hansoms and cabs to be seen in circulation on the streets of Manhattan Island, for the energizing of which a large battery room is required. The room is in fact slightly over 300 ft. long by 42 ft. wide, and 26 ft. high and, as can readily be imagined, it is a difficult place to light, not only on account of the darkness at almost all times, but because of the dense blackness of the storage battery boxes and the general absence of light-reflecting surfaces. Moreover, the frequent emission of fumes from the sulphuric electrolyte militates against the permanence of the ordinary electric light fixtures and appliances, so that from the first it has been found a difficult problem to light the space properly. The room was at one time lighted by fourteen 5-amp. arcs, taking, say, 60 to 70 amp. at 115 volts. It was necessary, however, to remove the mechanism of the arcs from the hood and to place it under a separate cover on account of the acid fumes from the batteries. There was, moreover, considerable difficulty in getting the arcs to work, and the results were never wholly satisfactory. Under all these circumstances, it was thought worth while to make a trial of the Cooper Hewitt mercury vapor lamp and 10 of these at 3 amp. each on the same 115-volt circuit have now been in use for about three months. The New York Transportation Company is very much pleased with the installation, and the current consumption is cut down about one-half. The lamps are run practically twenty-four hours a day. The general effect of the illumination can be seen from our half-tone cut, which, however, does not bring out the fact that the light given is so strong and penetrating that an examination of the batteries can now be made by the attendants with much greater ease and exactitude than ever was possible before.

While this may appear to be a large room for such illumination, we are able to give the data with regard to three other large spaces which the Cooper Hewitt Company has lit successfully. The table includes also the current consumption, the area lighted per lamp, and the area lighted per ampere consumed. Cooper Hewitt lamps are also being used very successfully in photography for taking this way as the tubes can easily be arranged in the regular solar blue print frame.

Character of work.	Area of Room.	No. of lamps.	Current Consumed. Amps.	Current Consumed. Volts.	Area lighted per lamp.	Area lighted per amp.
Draughting room	2,140 sq. ft.	8	3 1/3	110	265 sq. ft.	80 sq. ft.
Business office	1,100 sq. ft.	3	3.3	110	366 sq. ft.	110 sq. ft.
Leather factory	12,000 sq. ft.	30	3.3	55	400 sq. ft.	121 sq. ft.

For general illuminating purposes three types of lamp have now been developed. Two of these are of 700 cp. and the third is of 300

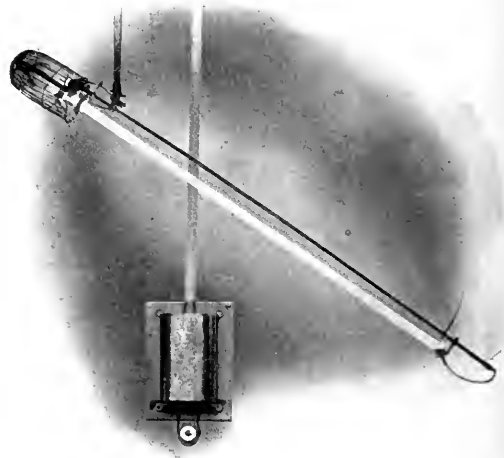

FIG. 2.—MERCURY VAPOR LAMP.

cp. One of these, known as the V-5 type, shown in Fig. 2, is the tube employed in the New York Transportation Company's battery room, and is started with a tilting method. The new type is of half size and can be operated two in series on 110-volt direct current.

FIG. 1.—BATTERY ROOM OF NEW YORK TRANSPORTATION COMPANY, LIGHTED BY VAPOR LAMPS.

pictures, for printing, for enlarging and for reducing. The photo-engraver also finds the lamp more economical of current, securing a more even illumination of the copy and faster printing on sensitized copper. A large amount of blue printing has also been done in

It is the type employed in business offices and for such places as the leather factory enumerated above. It is intended for general illumination and can be run in a horizontal position, whereas its predecessor, of the same candle-power, had to be run vertically or at an inclined angle of 30° from the horizontal. These lamps are started by the tilting method, which as a general thing appears to find preference over that involving the use of a kicking coil. Amongst recent orders for such lamps has been one of fourteen for James A. Hearn & Son, for their large dry goods store on Fourteenth Street, New York City. These tubes have been installed in their shipping and packing departments. It will be gathered from the above data that the Cooper Hewitt mercury vapor lamp has already made a distinct place for itself in the art and is rapidly gaining ground, not only in competition with older illuminants, but under circumstances which renders it peculiarly and sometimes exclusively available.

General Electric Oil Switches.

The extensive use of high-potential distribution systems and the widespread introduction of alternating-current motors and other devices introducing inductance have necessarily required radical changes in switches. The opening of circuits of considerable current value with inductive loads is not possible with old types of switches which were quite adequate for the service for which they were designed. These circuits are controlled with great facility and certainty by the oil switch, and this device is essential for the sure control of most modern alternating-current systems. Though of comparatively recent introduction, it has already been differentiated for many classes of service.

The accompanying illustrations show four types of such switches made by the General Electric Company. That of Figs. 1, 2 and 3, known as "Type F Form I," is designed to rupture loads which under emergency conditions cannot exceed 850 to 1,200 kw, three-phase, at potentials not exceeding 2,500 volts. Fig. 4 shows "Type F Form F" switch, designed to rupture loads which under emergency conditions cannot exceed 3,500 kw, three-phase, at potentials not exceeding 6,600 volts. In Figs. 5 and 6 are shown "Type F Form K" oil switch, designed to rupture loads which under emergency conditions cannot exceed 7,000 kw, three-phase at potentials not exceeding 13,000 volts. Finally, Fig. 7 shows "Type F Form H" switch. used for the interruption of circuits carrying power in excess of that which may be regarded as the limit of the switch of the other types.

The switches of Figs. 1, 2 and 3 are manufactured double, triple and four-pole, both single-throw and double-throw, and are designed in two forms: First, for mounting on switchboard panel, as shown in Figs. 1 and 3; and second, for mounting on separate base or wall, as shown in Fig. 2. This switch is adapted for use independently of a switchboard for the operation of induction motors, etc.

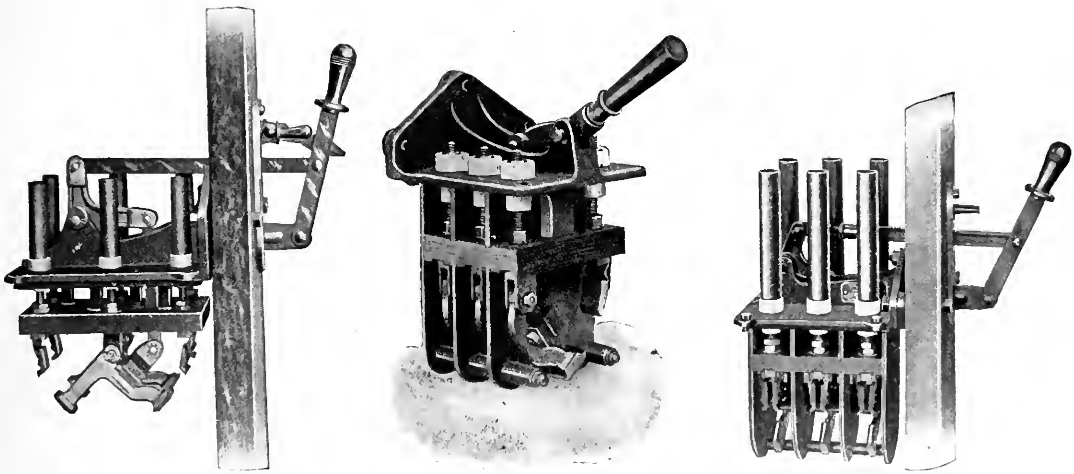
The cast-iron frame is designed to carry the mechanism, insulators and all live parts of the switch. Projecting lugs, from the under side of the frame, hold in position the base to which are attached the contacts and barriers. The switch is single-break—one end of the blade being clamped in a hinge clip by means of spring washers. The blades are joined together by means of a cross-bar, to which is attached the link for operating the switch. The stationary contacts are of the finger type, similar to those used in the General Electric street car controller. The oil vessel is supported from the frame and may be removed without disturbing any part of the switch. A red line indicates the proper oil level when the vessel is removed.

When in position on the switch all live parts and the base supporting the contacts are submerged in oil. The mechanism for working the switch mounted on the panel consists of an operating lever on the front of the board, which is connected by a link to a bell crank on the frame casting. The bell crank is connected to the cross bar of the switch by a second link. For the double-throw switches a lock is provided which prevents the switch from being thrown from one set of contacts to the other unless desired by the operator. This lock consists of two steel links pivoted on the escutcheon which locks the handle lever in the off position. When the oil switch is open it can be thrown on either set of contacts by lifting the locking handle which releases the catch. The switches, designed for mounting on separate base or wall, are equipped with a similar lock which is attached to the frame casting.

The use of this type of oil switch is recommended in connection with circuits which have to be opened under inductive load at voltages of 2,500 or less. The maximum load the switch will safely open is 700 kw single-phase, 1,200 kw three-phase, or 1,400 kw quarter-phase. It is designed in three current-carrying capacities, namely, 150, 200 and 300 amp.

The oil switch of Fig. 4 is manufactured especially for use on systems which require double-throw switches in connection with circuits of greater kilowatt capacity than that for which the above-mentioned switches are designed. It is designed for mounting on back of panel or for remote control, and is operated by means of a handle lever mounted on the face of the board. Double-throw switches are supplied with a locking catch which is released by means of a pull-rod passing through the panel. This lock has the same function as the locking catch o fthe oil switch described above and illustrated in Fig. 2.

The contact blades are carried upon a pivoted block of specially treated wood, and with the clips are supported from above by a cast-iron frame, forming a single element for mounting directly upon the switchboard panel or support. The oil vessel is supported from the frame casting as shown, and when in the operating condition the blades, blocks and all exposed live parts are completely submerged in oil. The oil vessel may be removed without disconnecting the switch or disturbing any other parts. The use of this switch should generally be limited to circuits where the double-throw arrangement is unavoidable. When single-throw switches of these



FIGS. 1, 2 AND 3.—OIL SWITCHES.

capacities are required the oil switch to be described later is preferable. The switch is made for voltages from 600 to 6,600 and currents from 125 to 300 amp.

The oil switch of Figs. 5 and 6 are designed single, double, triple and four-pole, and in two general forms, namely, the back of panel form for mounting directly upon the switchboard. This switch may be mounted upon a separate base equally well, and supported on an auxiliary framework. The second form is for remote control for operation in fire-proof cells or at points remote from the switchboard. Either form is arranged for hand-operation, being opened and closed by hand, and may be equipped with tripping devices which open the switches automatically on overload.

A cast-iron frame constitutes the body of the switch to which are attached all live parts and necessary operating links. The stationary contacts to which the leads are fastened are supported by insulators thoroughly insulating them from the frame casting. Controller finger contacts, which are readily replaced, are used instead of clips. A contact bar which moves in a vertical plane is carried by a rod of specially treated wood. In this manner a hinge contact is obviated and the switch made double-break. In case of double, triple or four-pole switches, the wooden rods carrying the contact bars are joined to a common cross-head which is lifted vertically in closing the switch. On the single-pole switches the rod is lifted directly by a lever, which is pivoted in the rear of the frame casting.

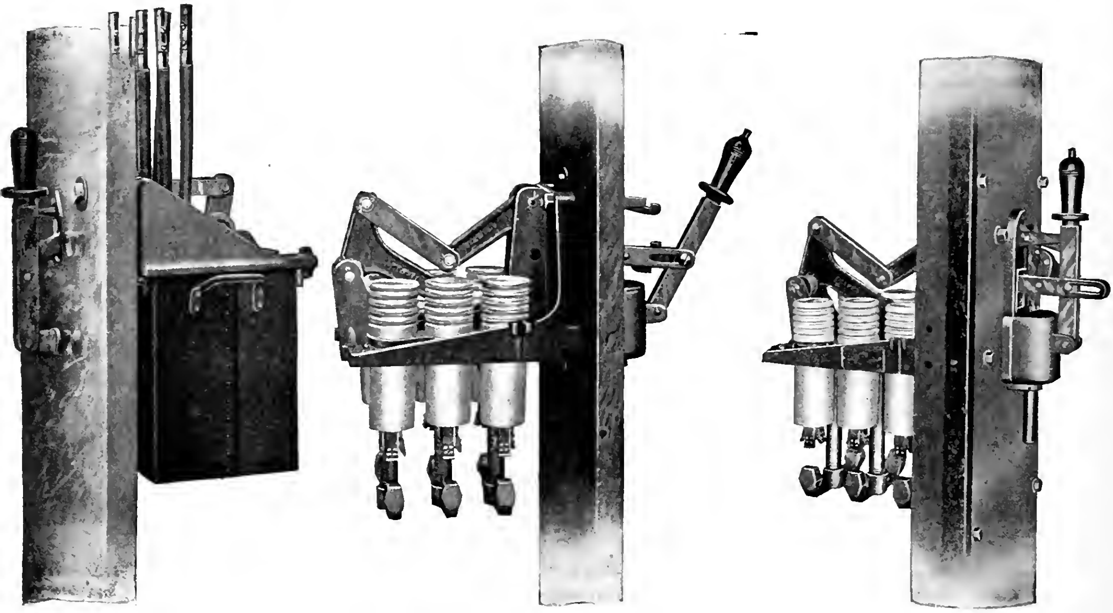
The links and levers forming the switch mechanism proper are so designed that a toggle enables the operator to close the switch with great ease. When the switch is equipped with an automatic trip the topple is set below center, so as to bring more or less pressure upon the tripping link, which, when buckled, allows the switch to open. If the switch is not arranged for an overload release the toggle lever is thrown past the center and the switch is locked in. The oil vessels for the double, triple and four-pole switches are lined and divided into individual compartments by means of wooden barriers.

The oil switch mechanism is connected by a link with the operating lever on the front of the board. When the switch is non-automatic the lever with the escutcheon and fulcrum are the only exposed parts on the front of the panel.

When the switch is electrically tripped the coil and tripping links are located on the front, and in plain view of the operator. A single coil is enclosed in a cast-iron magnet frame forming a part of the escutcheon. The double link connecting the switch mechanism and the operating lever is slotted and held in position by means of a tripping toggle. The core of the solenoid buckles the toggle links and allows the switch to open free from the hand lever. The handle remains in the closed position where it is held by a catch and may be released by means of a thumb push-button. The links projecting out beyond the hand lever indicate that the switch has opened automatically. The tripping link is so designed that it will immediately trip out when contact is first made if the switch is closed on overload or short circuit. This makes it impossible to damage apparatus due to short-circuit conditions.

When this form of oil switch is located at a remote point from the operating stand or switchboard, or placed in fire-proof cells, the operating lever is connected to the switch mechanism through a series of rods and bell cranks. The double, triple and four-pole switches are operated directly from the switch mechanism proper and may be located either straight back from the operating handle or at an angle with the face of the switchboard. The single-pole switches are connected up in groups of two, three and four elements to a common shaft, which is connected in a similar manner to the operating lever. If the operating lever is not located directly in front of a point on the shaft, an angular mechanism will be required.

The remote controlled triple-pole switches are made electrically tripped in the same manner as the switches mounted on the panel. For the single-pole switches the trip coil is mounted at the shaft. When the magnet is energized, the switch is released from the operating mechanism which remains in a closed position. A small switch is provided which closes a lamp circuit, indicating that the oil switch has been electrically tripped. When the switch is opened by hand the lamp does not light and the handle lever indicates that the oil switch is open.



Figs. 4, 5 and 6.—Oil Switches.

The 13,000-volt, triple-pole switch, mounted on the panel, is rated to rupture 6,000 kw, three-phase: and the triple-pole or three single-pole remote control switches are rated to rupture 7,000 kw, three-phase. It is not, however, recommended that the switches, when mounted on panels, be used up to the limiting capacities. If the emergency load will exceed 4,000 kw, three-phase, the remote control, triple-pole switch, mounted in the cell, is recommended.

The use of single-pole switches is recommended, for they permit a complete isolation of each phase, practically eliminating the possibility of a short-circuit between the buses in the station. The increased expense of the use of single-pole switches will usually be justified on account of the additional safety when the emergency load can exceed 5,000 kw, three-phase.

The frames of the single-pole switches should not be grounded or connected together by a metal framework or other electrical connection. This type of switch is made in capacities from 600 to 1,300 volts and 100 to 1,200 amp.

The cellular switch shown in Fig. 7 is manufactured single-throw only and is designed for exceptionally heavy work where the kilowatt rupture capacity is greater than that for which the other switches described are suitable.

These switches are motor-operated, thus allowing them to be located at the most convenient point to suit the general station arrangement. The operation of the oil switch is accomplished by a small hand-controlling switch, generally mounted on the panel, with the

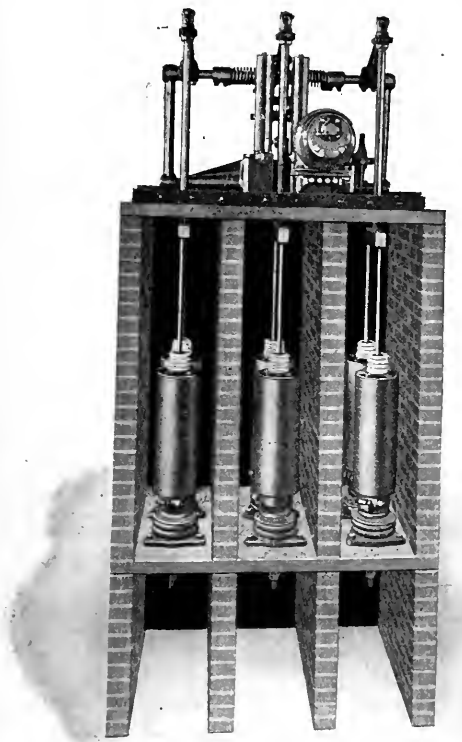


FIG. 7.—CELLULAR SWITCH.

instruments which are in the circuit controlled by the oil switch.

The switch can be made automatic by using a relay, operated by current transformers, which closes the direct current operating motor circuit. The standard voltage for the operating motors is 125, but they may be wound for other voltages when desired. In some cases the switches have been arranged for hand operation, but this method of operation should be considered special. All of this type of switch, however, can be operated by hand with a ratchet wrench, which is specially designed for this purpose and to protect the operator against injury when the crank shaft passes over center.

The switch has six breaks for a triple-pole, each break being in a separate oil receptacle, thus securing a device of great efficiency with a small amount of oil. In addition to this isolation of the breaks, each phase is enclosed in a fire-proof brick compartment, making it impossible for trouble in one phase to be communicated to another. The cells are constructed of brick with top and bottom slabs of slate. The following capacities have been developed: 60,000 volts, 100 amp.; 30,000 volts, 200 amp.; 13,000 volts, 300 amp.; 13,000 volts, 500 amp.; 2,500 volts, 1,000 amp.

This cellular type of switch has been successfully employed in the plants of the Metropolitan and Manhattan Railway Companies, the New York Gas, Light, Heat & Power Company, and the New York Edison Company, of New York City; the Niagara Falls Power Company and the Aurora, Elgin & Chicago Railway Company.

Blake-Knowles Multicurrent Feedwater Heater.

We illustrate herewith a vertical multicurrent feed water heater of Blake-Knowles type introduced by the International Steam Pump Company. In this heater the tubes are arranged in six segmental groups, and the water passes simultaneously through the tubes of each group and successively through the groups. At the top and bottom the tubes terminate in headers, which are divided by partitions which connect adjacent sets. The water entering the water inlet at the side of the heater near the bottom passes up through the first nest of pipes, through the header into the second and down to the lower header into the third, and so on until it issues from the sixth nest through the water outlet. The course of the steam is

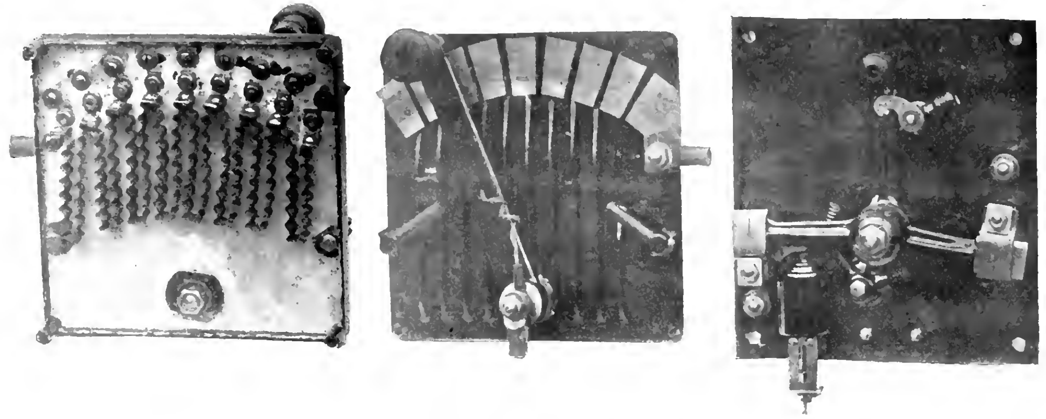
MULTICURRENT HEATER, VERTICAL TYPE.

through a path gradually decreasing in cross section. Entering at the steam inlet near the top of the heater it passes down over three sets of the water tubes, the cross section in this chamber being half the total circular area. The diametrical baffle plate extends from the top of the heater nearly to the bottom and causes the steam to pass up through the two adjacent chambers, each having one-sixth of the cross sectional area of the heater. The baffle plates dividing these chambers from the remaining chamber extend from the bottom of the heater nearly to the top, and the steam next passes downward through a cross sectional area equal to one-sixth of the heater and is finally discharged from the steam outlet at the bottom. In this way the path of the steam at each change of direction is cut down one-third and compensates for the reduction in volume due to condensation, with the effect of producing a nearly constant velocity.

The engraving shows an exterior view of a vertical heater of 800 hp size, in which the parts are disposed as just described. A horizontal form is also made, the theory of operation of which is practically the same though the construction is somewhat modified. In both forms the tubes are of composition giving a high efficiency in the absorption of heat, as well as long life. They are easily accessible for cleaning and allow for expansion and contraction, thus making it possible to use copper or brass tubes if the occasion requires. At the ends the tubes are expanded and secured into two heads, one of which is rigid and part of the main casing, while the other is bolted to a steel plate or diaphragm, the periphery of which is attached to the flange of the heater shell. This arrangement takes care of unequal expansion between the tubes and the shell. Another excellent feature is the absence of stuffing boxes or packings of any kind, doing away with the liability of leakage of feed water. The cross sectional area between the tubes is greater than the area of the exhaust pipe, so as not to cause unnecessary obstruction to the flow of steam, and avoids excessive back pressure. The condensation of the steam accumulating in the steam passages is removed through drip pipes. Blow-offs are also provided to keep the heater clean and free from sediment. Access to the heater is had by removing the heads. The tubes of the vertical heaters can be cleaned from the top, and those of the horizontal heaters from either end. The heaters are made in sizes up to 500 hp.

Rheostatic Combination for Electroplating.

The Ward Leonard Electric Company, of Bronxville, N. Y., has just brought out a rheostat for electroplating work. Fig. 1 shows the back of the electroplating rheostat used for control at the tank and Fig. 2 shows the front view of this rheostat and a special circuit-breaker. The working is as follows: A piece of apparatus which is to be silver-plated—with a certain specified thickness of plate—is suspended in the tank on a balanced beam. Current is turned on and when the exact amount of silver has been deposited, the added weight causes the balanced beam to fall and an auxiliary circuit



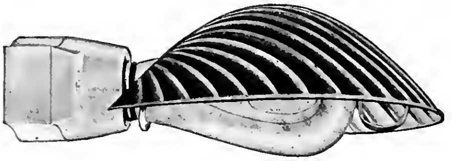
Figs. 1, 2 and 3.—Electroplating Rheostat.

through the overload coil of the circuit-breaker shown is automatically closed. The opening of the circuit-breaker breaks the main line and the current causing deposition is shut off. The rheostat shown is 11 by 11 by 4 in. in dimensions, has a resistance of .015 ohms, and a normal carrying capacity of 150 amp. It is equipped with self-aligning renewable shoes, renewable segments and a flexible connecting strip between the shoe contact and the line terminal preventing any drop of potential in the lever of the rheostat.

Aluminum Reflectors.

A novel and simple addition to electric lighting appliances and to the resources of the store window illuminator has just been brought out by the progressive firm of R. A. Schoenberg & Co., 1906 Sixth Avenue, New York City. The Sarco parabolic aluminum reflector, which is here illustrated, can be applied to the lamp without regard to socket or receptacle, or fielding receptable, the lamp fitting onto either. This enables a window to be wired with regular fielding receptacles, and by having the Sarco reflector applied direct to the lamp an even better reflecting power is acquired than by using an expensive mirror trough reflector. By its peculiar shell shape it gains at once in reflecting power, as shown by actual photometer test. The lamp setting closer to the reflector's surface reflects considerably more light than it would at a greater distance.

The Sarco parabolic aluminum reflector, owing to its simple and peculiar construction, is also an admirable reflector for the purpose of a desk illuminator, as when the reflector is clamped to the lamp, the bottom of the lamp is nearly submerged by the reflector (or covered, according to the position of the reflector), thus permitting no possibility of the light striking the eye. Being also of aluminum, it has the advantage of being so light in weight and adapts itself readily to the purposes of almost any kind of a desk lamp or portable.



Aluminum Reflector.

The finish of the Sarco reflectors is a solid smooth green enamel and the parabolic reflector in position resembles a green sea shell. Owing to its construction, it is possible to use the appliance without screws or clips. One of the chief uses to which the Sarco reflector can be applied is existing cluster lighting, as where a cluster is fitted with a porcelain shade the Parabolic reflector can be clamped direct on the lamp, thus giving the cluster the appearance of an elegant fixture, while at the same time doubling the quantity of the light. The Sarco deep cone reflector brings the polished surface of the reflector so close to the lamp that an actual test with it an 8-cp lamp will give as much light as an ordinary 16-cp light without the reflector. By the simple arrangement in the neck of the deep cone reflector, it can be applied without shade holder wherever desired, as in factory lighting, show rooms, etc.

Engine Builders' Association Council Meeting.

A meeting of the council of the Engine Builders' Association of the United States was held May 10 at the Astor House, New York. Among those present were Mr. C. A. Gates, of the Russell Engine Company, of Massillon, Ohio, who is president of the Association; Mr. J. I. Lyle, manager of the New York offices of the Buffalo Forge Company, the recently appointed secretary; Mr. N. B. Payne, of the Payne Engineering Company, 26 Cortlandt Street, who is chairman of the council; Mr. S. F. Bagg, of the Watertown, N. Y., Engine Company, and Mr. Walter C. Kerr, of the Westinghouse Machine Company.

The meeting was called for the purpose of considering ways and means of procuring more uniform methods in the commercial end of the engine business. Preliminary arrangements were also made regarding the next regular meeting of the Association, which will be held in New York in December. Practically all the members of the Association are identified with firms which make a specialty of building engines for direct connection to generators.

Reaction Brush Holder.

The brush holder is an important part of the great majority of dynamo electric machines and is a feature which in direct-current apparatus has very often been neglected, while other parts of the design were excellent. The type of brush holder shown herewith, and now improved, has been familiar to the public for somewhat over ten years and embodies a number of qualities which have commended it to the users of dynamos and motors. The qualities aimed at in the device are all vital to successful and smooth running, namely, efficiency of contact between brush and holder, freedom or flexibility of the brush in following the commutator contour, absolute parallelism as to plane and motion, slight inertia of the moving parts, a minimum low resistance path, ease and simplicity of handling, and absence of complication in the device.

It will be seen from Fig. 1 herewith that the reaction brush holder includes but six parts. The castings for the body portion and the

FIG. 1.—PARTS OF BRUSH HOLDER.

pressure arm are made from a special composition containing about 90 per cent. of copper and of high conductivity. The contact surface, against which the brush presses in the holder, is subjected to a milling operation that produces a perfectly flat surface. The set-screws have special truncated cone points adapting them equally for a round, flat or v-grooved stud. The spring is simple with no adjusting screws or lock nuts, the pressure on the brush being regulated by changing from one notch to another, as shown in Fig. 2, where, as will be seen, one spring is in one position of the notches

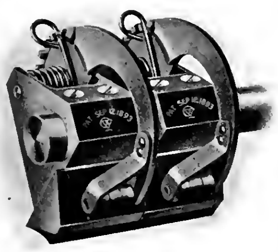


FIG. 2.—SPRINGS.

and another spring is in a different position. The end of the pressure arm is finely serrated, checking any possible tendency that might develop to side movement.

In operation the brush, which is preferably beveled at each end, is placed against the inclined contact plate and is kept always in positive contact therewith by the combined action of the pressure arm at one end and the reaction of the commutator at the other end. Hence, the brush is always maintained in intimate contact with the body of the holder, but so lightly or freely that the condition has been termed a "floating contact," as it leaves the brush entirely free to move away from or toward the commutator. The pressure arm performs the double function of pressing the brush constantly along the smooth contact plate against the commutator and in conjunction with the commutator reaction keeping it always in efficient contact.

The pressure arm is not associated with any box or frame and hence can follow the brush as it wears until it is practically used up. Moreover, the design of the holder permits it to be placed very close to the commutator, furnishing a minimum short path for the current. Owing also to the absence of any box surrounding the brush, all that is necessary to detach it for inspection or cleaning is to lift the pressure arm and simply take the brush away from the contact plate, in place of having to withdraw it from a clamp or box. This can be done even when the machine is in operation. Another feature is that a number of such brushes can be set side by side with no lost space between them, while the use of a flat contact plate without retaining sides makes it possible to use brushes of varying width, embracing the whole range of generator and motor sizes with three or four standard forms of holder. The brush is very quiet in operation and the successive refinements and

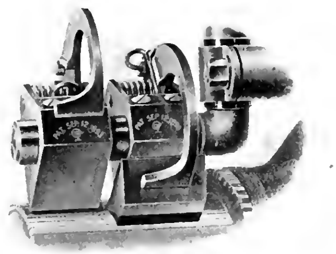

FIG. 3.—BRUSH HOLDER IN POSITION.

improvements have made it standard and satisfactory. The device is made by the Baylis Company, of 140 Washington Street, New York City.

"Dreamland" Lighting System of Coney Island.

The Brooklyn Edison Company has installed a 2,200-kw sub-station in the grounds of "Dreamland" for lighting and general power purposes in that new huge Coney Island amusement resort. There are two General Electric units of 1,000 kw each and two of 100 kw each. The power is taken from the union station of the company. It is transmitted at 3,600 volts, three-phase and is transformed at the sub-station to 170 volts alternating current. There are upwards of 150,000 lights, large and small, wired up in the resort. More than 50,000 decorative lights, it is claimed, are used to illuminate a massive tower in the grounds.

The tower is illuminated by thirty-six different circuits. On the apex 2,500 lights are used. The lighting of the tower is controlled by special remote control designed by Mr. C. C. Harley, the chief engineer for the Wonderland Company, which owns "Dreamland," and of which ex-State Senator Reynolds is president. About 600 hp of General Electric motors varying in capacity from 5 hp to 75 hp are used for operating the mechanism in the side shows, chutes, etc. There are more than 300 miles of special slow-burning fire and weather-proof cable used. The size of the cable varies from one to 1,400 cm. The National Conduit & Cable Company secured the contract for the bulk of the work. The switchboard has five panels. There are thirty 1,500-amp. switches which were manufactured by the F. A. La Roche Company.

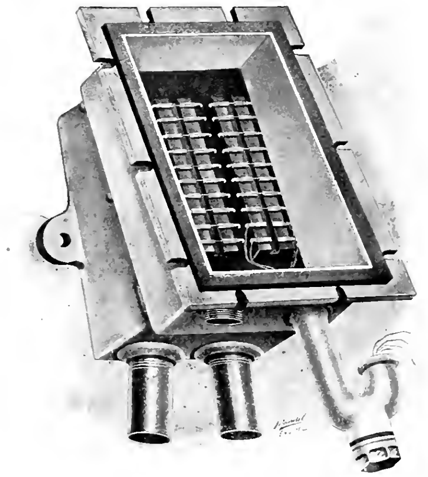
In the event of a break-down in the system, quick connection can be made with the Coney Island plant of the Brooklyn Edison Company, which will enable a 500-lamp control circuit in the grounds to light the resort to that extent.

It is almost needless to add that most of the features of this really wonderful pleasure resort depend largely upon electricity for their attractiveness, either in lighting effects, in spectacular displays or in the movement of mechanism. It is believed that quite a stimulus to such electrical work will be given by the creation of similar shows elsewhere.

Underground Distribution Box.

An excellent form of underground distribution box for telephone, telegraph, fire and police alarm service has been brought out by the Julius Andrae & Sons Co., of Milwaukee, Wis., and is herewith illustrated. It is known as the "Andrae O. K." Its aim is to avoid the usual dead investment in unused wires run from the ground to adjacent pole tops awaiting service, which perhaps never occurs. The box is of cast metal and the front side has a removable cover with brass bolts and screw connections, and is provided with a rubber gasket to keep out the moisture. The bottom of the box has two or more tapped openings for screw-threaded brass nipples, engaged by the cables, and these brass nipples and cables are united by soldering joints.

Inside the box is an insulating base of hard rubber and by means of screws this insulating base is fastened to a ledge projecting from



DISTRIBUTION BOX.

sides and ends of the box. The insulating base is provided with brass contacts mounted on hard rubber ribs, to which wires leading from the cables are attached, being first put through small individual openings, bringing them to the front, so that each connection is in plain view and work can be performed with rapidity.

The insulating compound is poured into the rear of the box—back of diaphragm, through an opening provided on top of the box and when completely filled is closed by a screw plug.

Each box is provided with two goose necks which can be attached whenever necessary under the front of the box through which wires are brought out to the pole or to the fire and police boxes, after which these goose necks are filled with compound. Thus this appliance affords easy and quick access to each conductor in a cable, for connection, test, disconnection, etc., and permits quick adjustment of the system to any emergency.

New Types of Attachment Plugs.

H. T. Paiste & Co., of Philadelphia, have brought out for 1904 a new P-K line of attachment plugs for both brass-capped and porcelain. The new "Pushin" style operates on an entirely new principle, as it is inserted and attached by simply pushing it into the socket, without any twisting of the cord. The two side springs, formed in exact shape to fit the Edison screw shell, hold the plug securely in place, while a third spring at the end completes the circuit. These springs are all of special phosphor-bronze. No. 430 is the standard P-K attachment plug and is made in Edison, T-H and Westinghouse styles. The brass caps are fibre-lined with a fibre bushing already in place in the cord opening. These caps are securely held to the base by two side screws which enter recesses in the porcelain base. All styles of P-K attachment plugs have cord openings

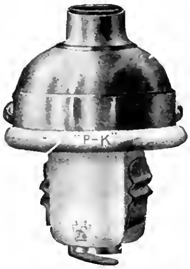


FIG. 1.—BRASS CAP.

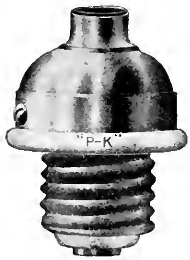

FIG. 2.—"PUSHIN."

FIG. 3.—PORCELAIN PLU

at least 13/32 in. diameter, so that they are easily wired with reinforced show window cord.

Desk Stand Telephones.

The Connecticut Telephone & Electric Company, of Meriden, Conn., has placed upon the market a new type of desk stand. All the working parts of this stand are entirely enclosed, making it free from handling and absolutely dust-proof. The hook switch is simple

DESK TELEPHONE.

and durable. The construction of this instrument is noteworthy for its high class of manufacture, both for finish and mechanical details. The instrument is equipped with the company's new solid-back transmitter and self-contained receiver, making the instrument one of the most powerful yet placed upon the market.

Big Telephone Consolidation.

Mr. J. G. Splane, president of the Pittsburg and Allegheny Telephone Company, says that within three months a consolidation of all the independent telephone companies between New York and Kansas will be perfected. It is said the enterprise is backed by Standard Oil interests. The headquarters will be in Chicago and the new combination will, it is claimed, have 1,000,000 telephones connected.

NEWS OF THE WEEK.

Financial Intelligence.

THE WEEK IN WALL STREET.—There was a complete lack of speculative interest, and extreme dullness prevailed. The renewed weakness in Steel stocks was the chief feature, common making a new low-record price by selling at 9. Otherwise price movements were unimportant, although there was some firmness in the standard railroad stocks in the face of the reactionary movement in the specialties referred to. The news regarding steel and iron trade conditions was the probable cause of the weakness of the Steel stocks. Some manipulative activity developed in Amalgamated Copper, which hardened slightly, on reports that a compromise with the Heinze interests was possible. The industrial and traction stocks as a class were rather neglected, Metropolitan Street Railway being the only one to display any irregularity. Allis-Chalmers common closed at 6, and preferred at 39½, the latter being a net loss of 1 point. General Electric ranged between 152 and 158, closing at 157, and Westinghouse closed at 155 after having reached 154. Brooklyn Rapid Transit closed at 45¾, a gain of ⅛ point, and Metropolitan Street Railway made a net gain of 2⅛ points, closing at 110¾. Bell Telephone ruled steady throughout the week, the closing price being 126⅜, a net gain of ⅜ point. Western Union lost 1⅛, closing at 88. The curb market was featureless, the general list being a little lower in price in sympathy with the reactionary tendency of the Stock Exchange list. The volume of business was very light. Interborough Rapid Transit lost 1½ points in the week's transactions, closing at 10½. Following are the closing quotations of May 17:

MONEY FOR GOOD INVESTMENTS.—The *Wall Street Journal* states that between January 1, 1904, and May 14, 1904, 135 days, there have been underwritten and sold in the United States securities aggregating over $600,000,000. It has compiled a list showing the principal items that make up this total and the companies that have issued and sold the securities. From this list it has in most cases omitted all issues under $1,000,000, and has not attempted to list securities of small companies or in fact any other securities than those which are well known to the investing public of Wall Street. If the count included all companies the aggregate would probably run over $700,000,000 of securities. From this list it appears that new securities have been sold to the investing public since January 1 at the rate of about $4,450,000 a day. The capitalization of the citizens of the United States has been increased about $8.00 per capita in 135 days. It is impossible, of course, to say how much of the money raised on these securities came from abroad. Probably something over one-sixth of the entire amount was subscribed by foreigners. It says: "The sale of this aggregate of securities in so short a time, coupled with the fact that money can be borrowed to-day in Wall Street at 2 per cent., is suggestive of the tremendous capacity of the United States for the creation and maintenance of legitimate industrial and railroad enterprises." The list includes the following items: General Electric, $3,525,000; Westinghouse, $2,000,000; the following tractions: Metropolitan, N. Y., $2,300,000; Third Avenue, $2,000,000; Central Crosstown, $2,250,000; B. R. T., $4,000,000; Twin City, $3,500,000; Detroit United, $500,000; St. Louis Transit, $8,000,000, and the following telephone securities or notes: Am. Tel. & Tel., $20,000,000; N. Y. & N. J. T. & T., $2,252,000; Bell, of Canada, $2,000,000; K. C. Home Tel., $1,500,000; Keystone Tel., $3,500,000; Northwestern, $1,500,000.

UNITED GAS IMPROVEMENT.—The United Gas Improvement Company shows as follows for the year ending December 31, 1903, and preceding years:

	1903.	1902.	1901.	1900.
Net earnings	$4,027,529	$3,473,643	$2,535,288	$1,714,347
Sale of securities	....	....	....	1,672,424
Total net	$4,027,529	$3,473,643	$2,535,288	$3,386,771
Dividends	2,569,349	2,018,238	1,797,728	1,553,768
Surplus	$1,458,180	$1,455,405	$737,560	$1,833,003

President Dolan says: "It will be noted that the capital stock of this company has been increased to $36,674,955. During 1903 the gas companies in which this company is interested increased their sales 16.6 per cent. in volume over the sales of 1902. The business of the electric light and trolley companies, in which we are interested, increased 11.3 per cent. and 5.3 per cent. respectively. The net profits for the year of $4,027,529 is equivalent to 12.4 per cent. upon the capital actually invested, as the new capital was not paid in until July 1, 1903. Out of these net profits $2,569,349 was paid in dividends and the balance, $1,458,180, invested in the business."

CONSOLIDATED GAS.—The directors of the New York Consolidated Gas Company have adopted a resolution that the capital stock be increased from $80,000,000 par value to $100,000,000 par value. A special meeting of stockholders will be held on June 2 to vote on a proposition to issue $20,000,000 6 per cent. debentures convertible into stock after three years. The stock will be issued to provide for "additional improvements and betterments, the acquisition of additional property, the payment of any indebtedness of the company, whether now existing or hereafter contracted." The stock will be issued to stockholders at par, payable in 3 installments, of 30 per cent., 30 per cent. and 40 per cent., temporary receipts will be issued for each installment, convertible into debentures at the option of the holder.

DIVIDENDS.—The General Electric Company has declared a regular quarterly dividend of $2, payable July 15. The directors of the General Electric Company have voted to offer stockholders of record June 15 the right to subscribe for the new stock at par on the basis of one new share for each ten of the old stock. Subscriptions will be closed July 15 and payments must be made on or before July 20. Subscriptions will be received only for full shares. The directors of the Barney & Smith Car Company have declared the regular quarterly dividend of 2 per cent. on the preferred stock, payable June 1. American Railways Company directors have declared a dividend of 1½ per cent. (75 cents) per share, payable June 15, to stock of record May 31. The Philadelphia Electric Company directors have declared the regular semi-annual dividend of 2½ per cent. (18¾ cents) on the stock $7.50 paid, payable June 15.

INTERNATIONAL STEAM PUMP.—The profits of the International Steam Pump Company for the fiscal year ended March 31, 1904, were, it is officially stated, nearly as large as they were in the preceding fiscal year, when they amounted to $2,113,365, and after deducting interest amounting to $585,709, preferred dividends of $531,000 and common dividends of $590,400, there was a surplus of $506,156. The preferred dividend is cumulative, and the declaration of the usual rate of 1½ per cent. quarterly is expected. With respect to the common stock, however, at the present time, it is not so certain that the rate of 4 per cent. per annum, which has been maintained during the past two years and paid in quarterly installments of 1 per cent. each, will be paid, during the ensuing year.

JERSEY TROLLEYS.—The forthcoming annual report of the New Jersey State Board of Taxation will show Trenton to be the leading trolley centre of the East, with eighteen separate systems and subsidiary lines. It will also show that during the last year of all these lines only one of them paid any dividends. Of the more than sixty such companies in New Jersey only eight of them paid dividends. Their total capital stock is $85,061,880, and they have a total of 980,563 miles of track.

MEXICAN TELEPHONE.—The following is the report, in Mexican currency, of the Mexican Telephone Company, for the year ended February 29, 1904:

	1904.	1903.	Changes.
Telephones in service	4,904	4,478	Inc. 426
Gross	$274,876	$246,368	Inc. $28,508
Net	134,885	111,997	Inc. 12,888
Net revenue U. S. currency	52,523	37,745	Inc. 14,778

Commercial Intelligence.

THE WEEK IN TRADE.—The more favorable weather conditions have stimulated retail trade and farmers have been able to do considerable planting. The improvement in some lines of trade has extended to reorders from jobbers. Reports of industry in general, however, are of slackness, particularly in cotton, woolen and shoe manufacturing. A quieter feeling and easier prices prevail in the iron trade, as a whole. Production is on a large scale, but stocks are not increasing as yet. Sales of 40,000 tons of steel rails, 5,000 tons of bars, and of good quantities of structural material are reported from Chicago. The hardware trade is good, but lumber is not quite up to expectations. A strike of teamsters at Chicago interferes with building activity at that point. In Chicago warmer weather has helped trade in general; in the Northwest farmers are actively employed and this tends to keep down retail trade. On the Pacific coast trade is below the average at San Francisco, while at other places in that section fair business conditions are reported. At the East there is more doing among the jobbers. There was a decrease of 5 per cent. in railway earnings in April as compared with the corresponding month last year. Copper prices are still firm, but the demand for consumption is dull. Quotations are unchanged, at 13⅜c. to 13⅝c. for Lake, 13⅛c, to 13¼c. for electrolytic, and 12⅞c. to 13⅛c. for casting stock. The exports for the month, so far, have been light, amounting to 4,300 tons. The business failures during the week ending May 12 numbered 201, as reported by *Bradstreet's*, against 176 the previous week and 182 the corresponding week in 1903.

SHANGHAI MUNICIPAL TRAMWAYS.—The firm of Fearon, Daniel & Co., of China, and of 90-96 Wall St., New York City, are advertising again for bids on the tramway concession for the Shanghai Municipal Council. It may be remembered that this was originally brought to the attention of the public as far back as 1898, when a contract was entered into between the municipality and the Brush Electrical Engineering Company of England. Due probably to the serious Boxer troubles which broke out in the Chinese Empire, the Brush Company did not proceed with the contract, so that the matter is again open for competition, and should receive the attention of American engineers. The firm in question have the full details of the concession, the main point of which is the deposit of $25,000 upon signing the contract. The road proposed is a fairly extensive one, comprising in the five specific sections, about 5¾ miles of double track, and 10¾ miles of single track to be equipped with span wire construction for double track, bracket for the single, and with iron or steel poles. The conditions laid down in the original tramway agreement must be complied with, but the agents state that a fair and reasonable proposal will have favorable attention on the part of the Municipal Council. The company putting in the road is permitted to collect from each first-class passenger 6 cents for a maximum distance of 1½ miles, and from second-class passengers 2½ cents. The company is to pay the council a yearly rental of $500 per mile of single track, and $750 per mile of double track. These and many other details are given in the papers in the hands of the firm named.

MOVING PLATFORMS.—It is stated that as an alternative to the proposition of the New York City Railway to give free transfers between their surface lines and the next rapid transit subway, if built by the Metropolitan, the Interborough Rapid Transit Company has formed a combination with the Schmidt & Gallatin moving platform syndicate to interchange transfers from the elevated or subway lines to a platform subway under Thirty-fourth Street. This proposition was laid before the Rapid Transit Commission last week by F. Kinsbury Curtis, lawyer for the syndicate. According to the plan of the combination, the Thirty-fourth Street crosstown connection from Ninth to Second Avenues, if made possible of construction, will be followed by like moving platform subways through Grand, Twenty-third, Fourteenth and Fifty-ninth Streets, to connect the elevated and subway lines. The proposition of Mr. Curtis covers the original route suggested by the moving platform people—over the Williamsburg Bridge, with a loop to the Battery—and a second route across Thirty-fourth Street.

EQUIPMENT FOR GRAND HOTEL EXTENSION.—Contracts have just been awarded through James Robert Moore, consulting engineer, 156 Fifth Avenue, New York, for the electrical equipment to be installed in the extension of the Grand Hotel, Thirty-fifth Street. The Construction Realty Company, 112 West Forty-second Street, has the contract for the construction and equipment of the building. The Buffalo Forge Company, through its New York City office, 39-41 Cortlandt Street, of which J. J. Lyle is manager, secured the engine contract. There will be three 90-hp and two 40-hp horizontal centre crank direct-connected to 50-kw. and 25 kw. generators respectively. The generators will be built by the Crocker-Wheeler Company. The equipment is intended for both light and power use.

ELECTRICAL SUPPLIES, ETC., FOR VENEZUELA.—The La Guayra Electric Light Company, of La Guayra, Venezuela, is placing considerable orders for electrical supplies, etc., through the export commission house of Kates & Bok, Orient Building. Mr. Carlos G. Palacios, chief engineer of the Caracas Electric Light & Power Company, is consulting engineer of the La Guayra Company. Mr. Palacios was recently on an extended visit here. At one time he was associated with the United States Electric Company, of Newark, N. J., and to his efforts is largely due the steadily increasing influx of Yankee electrical equipment, etc., into Venezuela.

CROSSLEY GAS ENGINE FOR LEXINGTON PLANT.—The Lexington (Ky.) Steel Ry. Co. has placed a contract with the Power & Mining Machinery Company (formerly Loomis-Pettibone Gas Machinery Company, of New York, successor to the Holthoff Machinery Company, of Milwaukee, Wis.), 52-54 William Street, New York, for a 500-hp Crossley gas engine to be direct-connected to a direct current, 550-volt generator of 300-kw capacity. The equipment will be installed in the existing steam power plant of the Lexington concern, whose capacity is about 2000-hp.

ELECTRIC CRANES FOR CANADIAN LOCOMOTIVE SHOPS.—Manning, Maxwell & Moore, 85 Liberty Street, have been allotted a contract for three electric traveling cranes for the Locomotive Machine Works, Montreal, which are now controlled by the American Locomotive Company. There will be two cranes of 10 tons' capacity each and one of 15 tons. The cranes will be built by the Shaw Electric Crane Company, of Muskegon, Mich.

ELECTRIC TRACTION OF MAZATLAN, MEXICO.—A concession has been granted to Janier Maxenim for the construction of an electric traction system in Mazatlan, a flourishing seaport town located in the State of Sinaloa, Pacific Coast, Mexico. There is at present a two-mile mule line. The new system will be about five miles long. Mr. Maxenim is expected to arrive here very shortly to place contracts for equipment.

ADIRONDACK ACTIVITIES.—The Paul Smith Hotel Company, Paul Smith's, Adirondacks, N. Y., will develop its water power on the Saranac River at Franklin Falls, N. Y., and build a power plant, from which will run transmission lines to Paul Smith's, Saranac Lake and Lake Placid, to operate an electric railway between the points named. The work will be done by the day, by its own men. Mr. A. C. Rice, State Mutual Buildings, Worcester, Mass., is the consulting engineer.

HOTEL TELEPHONES.—The hotels in Washington are "catching on" to the idea of a telephone in every room. The Chesapeake & Potomac Telephone Company, licensee for the Bell system, has secured contracts recently for the following hotels, all in Washington: Hotel Raleigh, 300 stations; Cairo Hotel, 80 stations; Hotel Rochambeau, 85 stations. The work of installing these telephones will begin at once.

EQUIPMENT FOR ASTOR ESTATE.—Col. John Jacob Astor has contracted through Mr. C. O. Mailloux, consulting engineer, for considerable electrical equipment to be installed for light and power purposes on his Rhinebeck estate. The De Laval Steam Turbine Company secured a contract for steam turbines. The Electric Storage Battery Company, of Philadelphia, has also been allotted a good-sized contract.

EXPORT TRADE.—The exports for the ten months including April amount to $1,277,859,235 or $54,000,000 more than last year; and the imports to $829,002,914 or about $35,000,000 less than last year. The excess of exports for the ten months is $448,856,321. For the month of April merchandise exports were $109,995,160, and imports $83,496,521, an export excess of $26,498,639.

ALLIS-CHALMERS-BULLOCK.—The Canadian business of the Allis-Chalmers Company, which recently acquired the Bullock Electric Manufacturing Company, of Cincinnati, will hereafter be conducted by a new organization bearing the name Allis-Chalmers-Bullock, Ltd. The works and principal offices of this important new Canadian company are in Montreal.

LIGHTING EQUIPMENT FOR HOTEL AMERICA.—The American Engine Company, of Bound Brook, N. J., has secured a third contract for lighting equipment to be installed in the Hotel America, Fifteenth Street and Union Square, New York. The outfit will include a 60-hp American Ball single engine to be direct-connected to a 35-kw. generator.

GORHAM MFG. COMPANY'S NEW PLANT.—Mr. C. O. Mailloux, 76 William Street, is consulting engineer for the electric plant which is to be installed in the new premises of the Gorham Manufacturing Company, silversmiths, at Thirty-sixth Street and Fifth Avenue, New York.

General News.

THE TELEPHONE.

JUNEAU, ALASKA.—All the mines in this vicinity within a radius of 40 miles will be connected by telephone during this summer. President Webster of the Juneau Light & Power Company is interested in the project.

LOS ANGELES, CAL.—The Home Telephone Company has decided to extend its system to San Diego in the near future. Material has been purchased and is now being delivered at San Diego.

LOS ANGELES, CAL.—The San Fernando Valley and Home Telephone Company is installing a system with a central office at Burbank, and lines will run to Toluca, Glendale, Eagle Rock and other suburban towns.

BOULDER, COL.—The city government of Boulder, Col., has granted an independent telephone franchise to Charles C. Townsend, of Greeley, Col., vice-president of the Morgan County Independent Telephone Company of that State. Mr. Townsend states that he and his associates intend to build a $100,000 plant in Boulder as soon as the work can be done, and that the rates will be $1 per month for residence telephones and $2 for business telephones on absolutely single party lines. It is understood that two per cent. of the gross receipts will be paid to the city of Boulder.

MOSCOW, IDA.—The Interstate Co-operative Telephone Company, of Moscow, has been absorbed by the Lookout Telephone Company of Lewiston, Ida.

LIBERTY CENTER, IND.—The Liberty Center Telephone Company is establishing an exchange and service in this town and county.

BLOOMFIELD, IND.—The New Home Telephone Company, of this city, will issue preferred stock to the amount of $100,000, to be disposed of for the purpose of securing funds to extend the lines and improve the plant.

STENDAL, IND.—The Stendal Home Telephone Company, has organized and incorporated. The capital stock is $10,000. John W. Stilwell, F. W. H. Schumaker, Wm. H. Eibert are among the incorporators.

EVANSVILLE, IND.—The Cooperative Telephone Company which advanced its rates a few weeks ago, was forced to readjust them on account of the wholesale "ordering out" of its telephones by the patrons. The old rates will be restored.

TERRE HAUTE, IND.—The stockholders of the Citizens Telephone Company have decided to install 32,000 feet of new cable and two sections will be added to the main switchboard at the central exchange. Another section will be added to the board at the North exchange. The cost of these improvements will be about $26,000.

ELKHART, IND.—The Central Union Telephone Company has been granted permission to lay conduits on all the streets asked except Franklin. It will expend about $75,000 in this city, greatly improving its present service and adding new equipment. It is said that the company will also improve and extend its plant to Goshen and between Goshen and Elkhart, the change to cost about $50,000.

EVANSVILLE, IND.—The Board of Public Works has granted a 30-year franchise to the Citizens' Telephone Company. The rental for business telephones shall not be more than $4 a month on full copper metallic circuit and $2 a month for residence instruments on metallic circuits. The Evansville Home Telephone Company is also seeking a franchise in this city. It is said that J. O. Parker, a banker, and other influential business men are back of the new company. In many respects the franchise submitted is the same as the one passed by the board to the Citizens' Telephone Company. The rules are to be $3.50 for business, $2 for residence and $1 for party line service. The Citizens Telephone Company has filed articles of incorporation. The capital stock is $100,000. A. F. Karges, M. L. Johnson, M. S. Sontag and others are the incorporators.

WAUKON, IA.—The Paint Creek Farmers' Telephone Company has been incorporated with a capital stock of $15,000. Wm. Rood is president.

OTTUMWA, IA.—The Iowa Telephone Company contemplates building a new exchange in this city, plans for which are being prepared by architect G. M. Kerns.

SUMNER, IA.—The stockholders of the Sumner Telephone Company have voted to sell, at public sale, its property, consisting of toll lines, exchanges, instruments, franchies, etc. The sale will take place at Sumner on May 25.

ALBANY, IA.—At the annual meeting of the stockholders of the Albany Home Telephone Company the following-named officers were elected: Howard Hendrickson, president; Irving H. Griswold, vice-president; George C. Lee, Jr., treasurer, and H. J. Price, Jr., secretary. The annual report shows an increase of 1159 in the number of telephones during the year with about 200 contracts on file waiting for installation. After operating for 15 months the company has earned 9 per cent. on the stock, after paying all expenses and fixed charges.

BOWLING GREEN, KY.—A company has been formed at Woodbourne, this county, to establish an independent telephone service at that place.

DANVILLE, KY.—The citizens of Junction City have organized a company at that place for the purpose of installing a telephone exchange. Dr. J. R. Steele was elected president.

CENTER LINCOLNVILLE, ME.—The Center Lincolnville Telephone Company has been organized to establish an exchange at this place. It has a capital of $1500. The officers are: President, J. S. Mullin; treasurer, W. D. Ross, both of Center Lincolnville.

BANGOR, ME.—The People's Telephone Company has been organized at Mercer for the purpose of building a line from New Sharon to Norridgewock. The capital stock is $27,000, and the officers are: President, C. K. Allen; treasurer, N. E. True, both of Mercer.

MECHANICSVILLE, MD.—The Southern Maryland Telephone Company has been organized with J. F. Coad as president.

ASHLAND, NEB.—The Ashland Telephone Company has filed articles of incorporation, with the Secretary of State, the capital stock being $50,000. It is the intention of this company to re-organize the old independent company at Ashland and to make a number of improvements in the service. The incorporators are Herbert H. Harndon, president; W. R. Shankland, secretary, and E. J. Rose, treasurer.

BATH, N. Y.—A new telephone company has been organized here with Isaac Rising as president.

COOPERSTOWN, N. Y.—The Cooperstown Telephone Company has increased its capital stock from $7000 to $10,000.

NORTH COLLINS, N. Y.—The North Collins Telephone Company has been incorporated with a capital stock of $5000. The directors are W. M. Ward, D. A. Dillingham and H. G. Parker, of North Collins.

WALTON, N. Y.—The Delevan Telephone Company, of Walton, has been incorporated with a capital stock of $3000. The directors are Grant Wilson, I. L. Brayman, Walton, and Thomas Carey, of Hancock.

BUCYRUS, OHIO.—The Bucyrus Telephone Company has increased its capital stock from $30,000 to $65,000. Mr. John A. Chesney is president and J. C. F. Hull, secretary.

CLEVELAND, OHIO.—The Cuyahoga Telephone Company has been ordered by the Board of Public Service to take down two miles of poles in the center of the city and place the wires underground.

ASHTABULA, OHIO.—At the annual meeting of the Ashtabula Telephone Company the following officers were elected: President, P. C. Remick; vice-president, W. R. Flower; secretary, S. W. Crosby; treasurer, D. B. Seymour. The company has added over 200 new telephones to its service during the past year.

MT. VERNON, OHIO.—At the annual meeting of the Mt. Vernon Telephone Company it was decided to re-incorporate the company under the laws of Ohio and to increase the capital stock from $100,000 to $150,000. The original company was incorporated under the laws of West Virginia. The company controls exchanges in Mt. Vernon, Fredericktown, Gambier, Centerburg, Twin City and Brandon, representing a total of 1603 telephones. The following-named gentlemen were elected directors: Frank L. Beam, Harry C. Devin, W. P. Bogardus, P. S. Kelser, E. O. Arnold, B. D. Herron, R. G. McClelland, H. G. Beam and J. W. Kelser.

CROWE, ORE.—The Crowe Telephone Company has been incorporated with a capital stock of $1000 to build a line between Crowe and Elmira, Ore.

ALBANY, ORE.—An independent telephone exchange is to be installed here. Messrs. W. R. Bilyue, L. C. Stratton, G. A. McCart and others have been appointed a committee to take action in the matter.

EUGENE, ORE.—The R. B. Electric & Manufacturing Company, of Kansas City, has asked the city council through W. D. DeVarney for a telephone franchise. Mr. DeVarney has opened an office at Portland, Ore.

PITTSBURG, PA.—The Wheeling & Pittsburg Telephone Company is to extend its lines.

PHOENIXVILLE, PA.—The Mutual Telephone Company has just formed here with R. K. Allsbach as president.

CANTON, S. D.—The Mutual Telephone Company has been incorporated with a capital stock of $20,000.

PIERRE, S. D.—The Eldon Home Telephone Company has been incorporated with a capital stock of $50,000.

LINWOOD, TENN.—The Linwood Telephone Company has been incorporated by H. D. Beadle, W. W. Young and others. It is capitalized at $1000.

EL PASO, TEX.—The contract for the construction of the new telephone exchange building for the Southwestern Telegraph & Telephone Company in this city has been let to C. W. Mackenzie for $11,000.

EL PASO, TEX.—The city council of El Paso has granted a telephone franchise to R. V. Bowden, attorney for the Southern Independent Telephone Company. The scale of rates provides that the minimum charge shall be $3 per month for business telephones and $2.17 per month for residence. This rate is to be charged when the company has from 1000 to 1500 telephones in use. The maximum rate shall be $4.70 for business and $3 for residence, to be charged when the number of telephones in use is between 4000 and 4500.

WHATCOM, WASH.—The Sunset Telephone Company will erect an exchange and general office building here.

TRINIDAD, WASH.—The Farmers' Telephone Company and the Bell Telephone Company offer to build a line from Trinidad to Wenatchee and Euphrata if $600 worth of stock is taken.

SPOKANE, WASH.—The Cheney & Spangle Mutual Telephone Company has been granted a franchise by the Spokane County Commissioners. The officers of the company are M. Ludwig, president; E. Thompson, secretary, and Saul Lind, treasurer.

SPOKANE, WASH.—The city council has granted to the Interstate Telephone Company a franchise to operate its system in this city. This will give Spokane patrons connection with numerous cities in what is known as the Panhandle district. The company has commenced the construction of a line from Spokane to Harrison, Ida. It will be 200 miles in length.

UTICA, WIS.—The Utica Telephone Company has filed articles of incorporation with a capital stock of $5000. The incorporators are Jasper Pickett, president, and Albert Parks, Robert Mackie and W. E. Munsil.

MINERAL POINT, WIS.—The Duke's Prairie Telephone Company, of Mineral Point, has been incorporated with a capital stock of $5000. The names of the incorporators are Charles Collicutt, James M. Pile, Joseph Whitford and William Harford.

Electric Light and Power.

BIRMINGHAM, ALA.—Saml. H. Lea, Chief Engineer, 305 Title Guarantee Building, this city, states that a power plant is proposed, but plans are not matured concerning size and details of construction.

ANNISTON, ALA.—The Clear Creek Mining Company has placed a contract with the Crocker-Wheeler Company for a 100-kw engine-type generator to be direct-connected to a new Ball & Wood engine in the company's plant at Arbacoochee. The new machinery will represent an outlay of $60,000.

CLARKESVILLE, ARK.—Col. E. T. McConnell has secured a franchise for lighting this city by electricity.

FAYETTEVILLE, ARK.—Bids are wanted for a 2-phase 120-kw alternator to be operated either by steam turbine or direct connected engine. It is understood that a day circuit will be maintained both for light and power. Other improvements are also being considered . F. W. Fratt, owner, 1001 North Broadway, Oklahoma City, O. T.

TEMPE, ARIZ.—The Tempe Pumping Company has been organized to develop water power for the production of electrical energy. The electric power will be transmitted to five sub-stations and will also be used for industrial purposes and lighting. Irrigation will also form a part of the company's work.

ALAMEDA, CAL.—A resolution has been passed by the council authorizing the electric light committee to install a day service in the municipal electric light works for power.

QUINCY, CAL.—The Quincy Water & Power Company has been incorporated by J. D. Goodwin witb a capital of $50,000. It is the intention of the company to improve the water works and to install an electric power plant.

BUENA VISTA, COL.—Articles of incorporation of the Chaffee County Electric Line, Power & Railway Company have been filed with the Secretary of State by Senator Wm. E. Mason, of Illinois, and associates. The company contemplates the erection of several water power stations at various points in the county.

NORFOLK, CONN.—The town authorities are considering the question of installing a new electric light plant.

SAND POINT, IDA.—The Sand Point Electric Company is now operating the city arc lights on the multiple system, but expects to install the series alternating current system during the coming fall. The company will also install a new 150-hp engine.

TABLE GROVE, ILL.—The citizens have voted to issue $4000 bonds to take over the electric light plant or install a new plant.

PERU, IND.—The Indiana Hydraulic Company is about ready to receive bids for the construction of a dam, electric power plant and electric railway between Vincennes and West Baden. J. Herff is president.

GREENSBURG, IND.—The Greensburg Gas Light Company has changed its name to Greensburg Gas & Electric Company and increased its capital stock $30,000. The purpose is to equip a plant and furnish electric light and power to the citizens of Greensburg.

MARION, IA.—The Marion Light, Heat & Power Company proposes to install new generators for street lights.

NEW ORLEANS, LA.—Bids will be received June 11 by Mordecai T. Endicott, Chief of Bureau Yards and Docks, Navy Department, Washington, D. C., for installing boilers, turbines, condensers, generators, etc., at the New Orleans Naval Station.

PITTSFIELD, ME.—The plant of the Pittsfield Electric Light & Power Company was completely destroyed by fire May 3. The loss was partially covered by insurance. A temporary plant is to be constructed.

CUMBERLAND, MD.—The following-named gentlemen have been elected officers of the Piedmont Electric Light & Power Company: President, H. B. Carroll; vice-president, Timothy Kenny; secretary, Norris Bruce; and treasurer, W. W. Shultice.

HOOSICK FALLS, MASS.—At the annual meeting of the Hoosick Falls Electric Light Company the following-named officers were elected: Frank H. Viele, president; D. L. Hall, vice-president; W. H. Tylee, secretary and treasurer, and Ralph D. Smith, general manager.

BOYNE CITY, MICH.—The Boyne City Electric Company proposes to develop a water power of 300-hp and will install a three-phase generator.

GRAND LEDGE, MICH.—Engineer H. A. Sprague, of Corunna, is stated to be interested in the Grand River Power Company, which is said to have secured an option on land along the river to be used for electrical purposes.

OTSEGO, MICH.—The Kalamazoo River recently formed a new channel around the Southern end of the big dam at the power plant of the Kalamazoo River Electric Company, depriving the plant of its supply of water. Most of the cities between Kalamazoo and Jackson, as well as the Jackson, Battle Creek Interurban road, depend upon this plant for power, and business was suspended temporarily while the Otsego dam was being disconnected from the others. The company has sufficient power to meet all demands. It will take about ten days to repair the damage.

FORT SNELLING, MINN.—It is proposed to increase the boiler, engine and generator capacity in the electric light plant at this post. Information can be obtained by addressing the quarter-master's department, Fort Snelling.

HANNIBAL, MO.—The Board of Public Works has closed several contracts for machinery, etc., for the new $100,000 municipal electric light plant.

PORTSMOUTH, N. H.—The board of tax assessors has decided to assess taxes upon the entire light and power plant of the Rockingham County Electric Light & Power Company of this city. This is the largest plant in the State and when it was built the city voted to exempt all new work of the company from taxation for a period of ten years. Since then the plant has been developed at a cost of $500,000. The supreme court decided that all votes of cities and towns exempting light and power plants from taxation are illegal and void.

NEWARK, N. J.—The following-named gentlemen have been elected officers of the Woodbourne Electric Light, Heat & Power Company of Sussex Borough: President, Charles A. Wilson; vice-president, C. H. Chrisman; secretary, A. W. Deldell; treasurer, Dr. H. D. Van Gassbeek.

SALISBURY, N. C.—The Salisbury Gas & Electric Light Company proposes to build a street railway five miles in length, install two new boilers, and new generators.

SANFORD, N. C.—The Sanford Electric Light & Power Company is extending its lines to Jonesboro, a distance of two miles, and will install about 500 additional lamps.

KENTVILLE, N. C.—The Kentville Electric Lighting & Power Company will probably install a small steam and electric unit for late night service. Judge Chipman, of Kent, is president of the company.

LEXINGTON, N. C.—The plant of the Lexington Water & Light Company was destroyed by fire on the night of April 30. Mr. F. W. Siebert is manager and G. W. Montcastle is president. The plant will be rebuilt.

DICKENSON, N. D.—Hughes & Dieters, proprietors of the electric light plant here, will install a new tubular boiler some time during the coming summer.

CINCINNATI, OHIO.—A number of local interests are forming a company to undertake the work of utilizing for power and commercial purposes the Ohio River from Pittsburg to Cairo. The object is to construct a system of reservoirs at the head waters of all the rivers and streams emptying into the Ohio along its entire length, thereby controlling the waters of the Ohio River. Another meeting of the projectors is to be held soon to decide whether the government shall be requested to conduct the enterprise, or whether it shall be carried out by private capital.

STAYTON, ORE.—The Stayton Electric Light Company expects to install a 250-volt booster in its plant here.

ROSEBURG, ORE.—The Umpqua Water, Light & Power Company was organized March 1 last by consolidating the Douglass Electric & Water Company and the Roseburg Water & Light Company. The capitalization of the company is $50,000. The officers are: President, Fred J. Blakeley; secretary, Dexter Rice; treasurer and manager, T. R. Sheridan; superintendent, F. H. Farrer.

BROOKSVILLE, PA.—The Solar Electric Company contemplates installing an additional dynamo and one 150-hp engine.

TARENTUM, PA.—Some improvements are contemplated in the municipal electric light plant at this place at a cost of between $10,000 and $12,000. The plant will be operated on the meter basis.

JEFFERSON CITY, TENN.—The Jefferson City Electric Company proposes to add some steam equipment to its plant.

CARTHAGE, TEX.—Mr. John C. Whitney, owner of the electric light plant here, proposes to give the plant a general overhauling and will probably install a more economical prime mover.

FOUNTAIN GREEN, UTAH.—The Big Springs Electric Company is considering the advisability of extending its electric lighting service to Ephraim, 12 miles from here.

LOGAN, UTAH.—Garff & Sons are making negotiations with the city council to establish and equip an electric lighting plant here, which is to be sold to the city after four years.

BURLINGTON, VT.—Bonds for $58,000 will be issued for a municipal electric light plant here. The city attorney is now looking into the legal questions connected with such an enterprise.

RUTLAND, VT.—The Rutland City Electric Company recently installed a new modern switchboard at its station. The board contains 11 panels of Vermont blue marble, each panel being 7 ft. high.

TAZEWELL, VA.—The Tazewell Electric Light & Power Company has been incorporated at Tazewell with a capital stock of $15,000. Joseph S. Moss is president.

HOOSACK, WASH.—The Washington Mining & Development Company in the Mt. Baker District is preparing to install an electric plant.

NORTHPORT, WASH.—The Northport Electric Company's plant was destroyed by fire May 4, entailing a loss of $4000. Mr. Robt. Morrell is manager and owner.

GLIDDEN, WIS.—There is an opening for an electric light plant in this place.

NEENAH, WIS.—In January last the city council awarded to the Fox River Valley Gas & Electric Company a franchise to light the city for a term of 20 years. Later this contract was annulled, and a similar one was let to the Wisconsin Light, Heat & Power Company, of which John I. Beggs, of Milwaukee, is the head. The Fox River Company has entered court to contest the annullment of its contract, and the Beggs company has agreed to indemnify the city against any damages or costs that may arise from the legal action.

NELSON CITY, B. C.—Bonds have been issued for the erection and equipment of a 3000-hp plant for power and lighting purposes.

BATHURST, N. B.—A contract was signed at Bathurst for putting in an electric light plant for lighting the town and village. The plant will be run by water power, which will be obtained from the Tamagouche River, two and one-half miles from Bathurst.

ACTON, ONT.—The electric light plant here, which is operated by the town, proposes to install a day power service.

CARLTON PLACE, ONT.—The Carlton Place Electric Light Company proposes to increase the capacity of its plant during the present season. Messrs. H. Brown & Sons are the proprietors.

The Electric Railway.

PRESCOTT, ARIZ.—Frank Wright, manager of the Prescott electric lighting system, of the local telephone system and of the new electric street railway, has a plan for penetrating the nearby mining districts with electric railways for hauling freight and ores.

MT. HERSEY, ARK.—The North Arkansas Electric Railway Company has filed articles of incorporation. The capital stock is $150,000, of which $30,000 has been subscribed. The officers are Griff Glover, of Bloomfield, Mo., president; E. K. Eby, of Jasper, Ark., vice-president; S. J. Norman, of Jasper, Ark., secretary and treasurer.

VISALIA, CAL.—The Visalia Electric Railway Company has been incorporated with a capital stock of $1,000,000 to build a 24-mile electric railway to run easterly from Visalia to Exeter, Lemon Cove and Lime Kiln Point. The directors are W. H. Hammond, Ben M. Maddox, Susman Mitchell, C. J. Giddings, all of this city, and Harold Wheeler, of New York.

DENVER, COL.—The Denver-Boulder Interurban Railway Company has been incorporated with a capital stock of $1,000,000. The directors of the road are: Ex-Mayor Henry V. Johnson, of Denver; Charles F. Potter, Judge Sterling B. Toney, of Denver; John R. McKinnie and L. L. Aitken, of Colorado Springs, and John H. Simpson and Percival Moore, the latter of Louisville, Ky. The company will be bonded for $500,000.

DANIELSON, CONN.—The Worcester & Eastern Railway Company, which is controlled by the New York, New Haven & Hartford Railroad, has made application to the Superior Court for New Haven County for a change of its name to "The Consolidated Railway Company."

GRANITE CITY, ILL.—At the annual meeting of the Venice, Madison & Granite City Railway Company, by unanimous vote the corporation was dissolved and the charter surrendered. The company sold out to the Granite City & St. Louis Railway Company, in which Governor D. R. Francis, of Missouri; Fred E. Allen and E. J. Spencer are the principal stockholders.

GENEVA, IND.—The Geneva Traction Company has filed articles of incorporation. The company is capitalized at $20,000. The purpose of the company is to construct an electric railway in Geneva and to Montpelier, Ind., and one also to Celina, Ohio, and will furnish electric light and power to various people and manufactories along the route. The company's office will be at Geneva and the concern will be managed by a board of seven directors, including A. G. Briggs, Charles Parks, E. F. Welch, J. H. Hardison, S. W. Hale, D. M. Shirley and W. J. Huter.

FOREST CITY, IA.—D. B. Lyons, of Des Moines, and an engineer, will survey for the proposed electric railway from Forest City to Cresco. It is now proposed to build to the Mississippi River, and a company with $1,000,000 capital will be organized.

LOUISVILLE, KY.—The Lebanon & Columbia Electric Railway has incorporated with a capital of $1,000,000. The line will be 42 miles in length. The incorporators are prominent business men of Lebanon, and W. K. Azbil, of Lebanon, is president. Arrangements for financing the project are said to have been made.

HENDERSON, KY.—The Henderson Street Railway, in which Joseph E. Bohannon and H. W. Richardson, of Louisville, and A. L. Rich, of Cincinnati, are large holders, will be rebuilt and extended. The work is in the hands of the Tennis Construction Company. It is contemplated by the owners of the property to extend the road to Evansville.

BOSTON, MASS.—The National Exchange Bank, of Providence, has filed two bills in the United States Circuit Court against the Lowell & Boston Street Railway Company and the Concord & Boston Street Railway Company, seeking appointment of receivers for each company. The bank alleged that the Lowell & Boston Company is indebted to it for $9,000, and the Concord & Boston Company for $10,000.

ST. LOUIS, MO.—On April 30, the first day of the World's Fair, the St. Louis Transit Company carried 927,000 passengers. Average daily volume of traffic since then has been from 350,000 to 400,000.

KANSAS CITY, MO.—The Metropolitan Street Railway Company has secured a permit to erect a power house sub-station at the southwest corner of Twelfth Street and Cleveland Avenue. It will be completed in about sixty days. The cost is estimated at $20,000.

KANSAS CITY, MO.—A charter has been granted for another electric railway between Kansas City and Topeka by way of Lawrence, Olathe and Rosedale. It is known as the Kansas City, Lawrence & Topeka Railway, and its capital stock is $1,000,000. The following-named officers have been elected: Henry G. Pert, president; George Leis, of Lawrence, vice-president; W. A. Bunker, Kansas City, Mo., treasurer, and J. G. Hughes, of Kansas City, Kan., secretary.

KANSAS CITY, MO.—The Kansas City, Burlingame & Western Electric Railway has filed articles of incorporation in Topeka. The capital stock is given as $2,000,000. The officers are: President, Hugh A. Holmes; vice-president, J. T. Pringle, Burlingame, Kan.; second vice-president, E. J. Hilky, Overbrook, Kan.; third vice-president, J. O. Southard, Allen, Kan.; treasurer, J. P. Slaughter, Burlingame, Kan.; secretary, Charles G. Taylor, Burlingame, Kan. The road incorporated will connect with the Kansas City & Olathe line at Olathe. It will run through Baldwin, Overbrook and Burlingame to Council Grove, a distance of 100 miles. Much of the right of way of the Burlingame line has already been secured. The road is to be in operation in eight or nine months. Cars may be running to Baldwin in five months. The line chartered is part of the system which includes the Kansas City & Olathe line, and the Kansas City, Lawrence & Topeka road. The Olathe line is to be in operation this summer. Electric cars may be running into Topeka by next spring.

RENO, NEV.—Money has been provided for the commencement at once of work on the proposed railway between this city and Sparks. California capitalists are the promoters, who are represented here by S. N. Griffith.

NEWARK, N. J.—The Public Service Corporation has announced the schedule of the passenger service between Jersey City and Philadelphia, which went into effect Friday, May 13. The first car leaves Jersey City at 8.35 A. M., and will leave Broad and Market Streets, this city, at 9.28 A. M., arriving at Trenton at 1.50 P. M. At Trenton close connections will be made with a boat of the Delaware Navigation Company for Philadelphia. The sail down the river will take about four hours. Three other cars will leave New York at 11.20 A. M., 2.20 P. M., and 5.20 P. M., and returning cars will leave Trenton at 8 and 11 A. M., and 2 and 5 P. M., arriving at Newark at 12.30, 3.32, 6.32 and 9.32 P. M. The cars will pass through Elizabeth, Westfield, Plainfield, Bound Brook and New Bruswick.

MIDDLETOWN, N. Y.—The sale of the Middletown-Goshen Electric Railway will be held May 26. The date of the sale was originally set for April 28.

ROCHESTER, N. Y.—The highway commissioners of the town of Wheatland have granted permission to the promoters of the Rochester, Scottsville & Caledonia Electric Railway Company to pass through that town. The road will be capitalized at $250,000. Articles of incorporation have been forwarded to Albany.

HUNTINGTON, N. Y.—The Huntington Railroad Company, owned and operated by the Long Island Railroad Company, has signed a contract with the Huntington Light & Power Company, whereby the last named is to furnish power to operate the road. The plant of the Light & Power Company will be about doubled in size. New engines will be installed at once. The power used at present is furnished by gas engines.

ELIZABETH CITY, N. C.—David E. Evans, president of the Elizabeth City Electric Light Company, is planning to organize a company to build an electric railway here.

COLUMBUS, OHIO.—The bill passed by the Legislature giving electric railways practical power of eminent domain in municipalities is now the law in Ohio, as the Governor has allowed ten days to elapse without either signing or vetoing it.

NORWALK, OHIO.—Citizens of Norwalk have subscribed nearly all the $100,000 in bonds to secure the building of the Sandusky, Norwalk & Mansfield Railway between Norwalk and Plymouth. Construction work on the road will probably start in the near future.

CLEVELAND, OHIO.—The Cleveland Electric Railway Company is closing a contract with the Electric Storage Battery Company, of Philadelphia, for a storage battery outfit to have a capacity of 1600 amperes for one hour. The battery will operate in connection with a booster set, and will be located on Detroit Street to assist with the loads on the west side lines of the company.

CLEVELAND, OHIO.—The Mansfield & Eastern Traction Company has placed a contract with the Reisinger-Proctor Company, of Pittsburg, for the construction of 17½ miles of road from Mansfield to Ashland by way of Mifflin, with a spur to Petersburg Lake. Plans for the road have been prepared by the General Engineering Company, of Cleveland, and it is stated that construction work will start before June 1. The bonded indebtedness of the company will be $450,000, and one-third of the amount has been underwritten. David Morrison, of Cleveland, is at the head of the company.

INDIANA, PA.—The Town Council has granted the necessary franchises to the Indiana Street Railway Company to enable it to construct its proposed lines.

WASHINGTON, PA.—The Wheeling & Elm Grove Railway Company, which operates from Wheeling to West Alexander, will extend its lines to Washington and form a link in the line from Pittsburg to Wheeling.

HARRISBURG, PA.—The Valley Traction Company has bought the Baltimore, Westminster & Gettysburg Electric Railway Company. The Valley Traction Company has also acquired the Hampden Street Railway and the South Middletown Electric Railway, their respective rights and franchises.

STROUDSBURG, PA.—The Northampton & Monroe Electric Railway Company, shortly to commence operations between Stroudsburg and Bangor, is to be extended to Mount Pocono, Tobyhanna and thence to Scranton. It is believed that the line will be constructed and in operation within two years.

UNION, S. C.—T. C. Duncan has organized a company to build an electric railway between Roebuck and a point on the Georgia Central & Northern Railroad, via Neal Shoals.

CHATTANOOGA, TENN.—At a meeting of the Rapid Transit Company stockholders it was decided to issue bonds to the extent of $1,000,000, of which $250,000 will be spent in improvements. The present officers of the company were re-elected.

SEATTLE, WASH.—The Seattle, Renton & Tolt Electric Railway Company has been incorporated with a capital stock of $750,000. The trustees are W. H. Goldson, P. J. Farley and Edwin S. Gill.

SEATTLE, WASH.—Articles of incorporation of the Snohomish & Cherry Valley Electric Railway are ready for filing. The capital stock of the company is to be $1,250,000. The road will connect Snohomish and Tolt by way of Monroe and Cherry Valley.

HALIFAX, N. S.—G. Martin Brill, of the J. G. Brill Company, of Philadelphia, Pa., is president of a company organized to construct an electric railway in Nova Scotia. The corporation will take over 50 miles of roadway that has already been surveyed.

TORONTO, ONT.—The Toronto Street Railway Company is increasing its power capacity by installing a plant which will bring the total output up to 10,000-hp, with a reserve storage battery capacity of 3000-hp in addition. The company has also secured an additional 200-hp from the old Metropolitan power house at Eglington, a suburban line recently secured by the company.

New Industrial Companies.

THE TURBINE ELECTRIC TRUCK COMPANY, of New York, has filed a certificate of increase of capital stock from $100,000 to $300,000.

THE INTERNATIONAL RAILWAY SIGNAL COMPANY, of Winston, N. C., has been chartered with a capital stock of $250,000. A. H. Eller and others are the stockholders. The purpose of the company is to equip railways with a new signal system and sell rights to use the same.

THE CLINTON STAMPING & ELECTRIC COMPANY will establish a plant at Clinton, Ia., for the manufacture of a combined lightning arrester, ground switch, fuse and lever cut-off for telephones. The company will also manufacture knife switches and engage in electroplating.

THE BLACK HAWK ELECTRIC COMPANY has been incorporated at Davenport, Ia., for the purpose of dealing, besides its present business, in electrical appliances, repairing automobiles, etc. The capital stock is $10,000. The officers of the company are W. A. Fuller, president; James E. Bayles, vice-president; John H. Eagel, secretary and treasurer.

THE MARTIN-REYNOLDS ELECTRIC COMPANY, of Little Rock, Ark., has been incorporated with a capital stock of $15,000, of which $4000 has been subscribed. The incorporators are Ed. Cornish, Robert E. Wait, M. B. Sanders, T. B. Martin, Jr., E. T. Reynolds, C. E. Robinson, Ed. M. Pennington, A. D. Reynolds, E. T. McConnell, R. D. Dunlap and D. T. Reynolds.

THE AKRON INSULATOR & MARBLE COMPANY and the Colonial Sign Company, both of Akron, Ohio, have consolidated under the title Colonial Sign Company. The plant of the Insulator Company will be removed to that of the Colonial Sign Company in South Akron and the new concern will continue to manufacture the same line of articles produced heretofore by the separate companies. The capital stock has been increased to $50,000. Mr. H. B. Camp is president of the new company; G. D. Chapman, vice-president; C. R. Quine, secretary; W. H. Motz, treasurer, and J. R. Hemphill, general manager.

Obituary.

MR. NELSON PERIN.—Mr. Nelson Perin, one of the leading financiers of Baltimore, Md., after a long illness, aged fifty-one years, died on May 12. He was one of the pioneers of rapid transit in Baltimore, and was the first president of the United Railways and Electric Company, which combined all the street railways of the city. He retired from the presidency of the company three years ago. Mr. Perin also was a promoter of the present system of electric lighting.

GEN. A. HICKENLOOPER.—The death is announced at Cincinnati, Ohio, of Gen. Andrew Hickenlooper. He rose from captain to brigadier in the Civil War, and was a famous commander of artillery in the Union Army. After the war he was civil engineer of Cincinnati, and for the past thirty years president of the Cincinnati Gas & Electric Company. He was Lieutenant-Governor of Ohio from 1880 to 1882. Gen. Hickenlooper was sixty-seven years old. He was long noted for his prominent connection with gas interests in Cincinnati and for the virulence of his opposition to electric lighting.

Personal.

MANAGER SCOTT, of the Cutter Company of Philadelphia, has returned from a short trip to Europe.

MR. H. A. RHODES, chief engineer of the Colorado Telephone Company, has gone from Denver to St. Louis on a combined business and pleasure trip.

DR. S. S. WHEELER, president of the Crocker-Wheeler Company, of Ampere, N. J., has just returned to New York from a brief trip to Europe.

MR. ERNEST F. LARNED, of Boston, formerly with Stone & Webster, has arrived in Tacoma, Wash., on a tour of inspection of engineering propositions in the Far West.

MR. JOSEPH H. THOMPSON, JR., has opened an office at 11 Broadway, New York City, for the purchase, sale or exchange of new and second-band electrical and steam machinery.

MR. D. MAZENET, managing director of the Mexican General Electric Company, which represents the interests of the General Electric Company, will pay a visit to the United States headquarters early next week.

MR. AUGUSTA WITZIG, of the Societe l'Eclairage Electrique de Paris is now on this side. The French concern is represented in the United States by the Goudey-McLean Company, 120 Liberty Street, New York.

MR. J. H. HALLBERG has opened an office at 45 Broadway, New York City, as consulting expert in electrical distribution and illumination, a branch of work for which his training and experience qualify him admirably.

MR. JAMES H. McGRAW, president of the McGraw Publishing Company, has been elected a delegate for New Jersey to the Republican National Convention which will meet in Chicago in June to choose a presidential candidate.

MR. J. C. McQUISTON, formerly secretary of the Publishing Department of the Westinghouse companies, has been made its superintendent and responsible head. He will be charged with matters of advertising, preparation of technical articles, etc.

MR. J. C. BOYNTON, toll traffic manager of the Colorado Telephone Company at Denver, has resigned his position with that company and gone to Newcastle, Pa., where he will probably continue his work in connection with telephone traffic problems.

MR. LOUIS F. PHILO, who for the past six years has been connected with the Wesco Supply Company, in the capacity of manager of the supply department, has become assistant manager of sales with the Ewing-Merkle Electric Company of St. Louis.

MR. J. G. WHITE, president of the electrical engineering and contracting firm of J. G. White & Company, Inc., New York, will sail for Europe May 24 on the North German Lloyd liner *Kaiser Wilhelm der Grosse*. He expects to be absent about three months.

MR. FRED A. GEIER, secretary and treasurer of the Cincinnati Milling Machine Company, who has been abroad some time, has just returned home from Europe, having greatly enjoyed the change and seen a good deal of industrial conditions on the other side.

MR. W. OWEN THOMAS, electrical engineer of the Michigan Lake Superior Power Company at Sault Ste Marie, Mich., has severed his connection with that large undertaking to become assistant to the mechanical engineer of the Chicago & Northwestern Railway Company, at Chicago.

MR. CHARLES H. HASWELL, known to all engineers the world over, celebrates his ninety-fifth birthday Sunday, May 22, and his friends in this city where he was born in 1809 are giving him a dinner at the Engineers' Club on Monday next. The veteran will enjoy a story and a cigar with the liveliest of them.

MR. JAS. R. CRAVATH recently addressed the Armour Institute of Technology branch of the A. I. E. E. on the subject of "Illumination," taking up first the general subject of how to secure the best results for a given expenditure of money for electric light, and following with some specific examples and practical suggestions.

ARTHUR FRANTZEN & COMPANY.—The electrical engineering and contracting firm of Arthur Frantzen & Company, Chicago and Baltimore, has entered the Mexican field. Branch offices have been opened in the Mexican capital under the management of Mr. A. B. Boynton. Mr. A. W. Maulsly will be assistant manager.

MR. H. M. DIEFFENBACH, who recently resigned as general manager of the Mexican end of the American Smelting & Refining Company, has beeen appointed general manager of the Compania de Minelales y Metales of Mexico City. This concern controls the Penobles Mining Company, which will be in the market for a big lot of electrical equipment very shortly.

MESSRS. J. CICERON CASTILLO and F. Mendoza Alvirez have recently established themselves in Morelia, State of Michoacan, Mexico, under the firm name of Castillo y Compania. They will inaugurate a department to be devoted to the installation of hydro-electric machinery, etc., for operating mines, etc., and have already obtained some fair-sized contracts.

MR. HERMANN RUETE, until recently associated with the export commission house of G. Amsinck & Company, Hanover Square, New York, is about to leave for Germany, where he will enter his father's firm, Ruete & Schutte, of Hamburg, which is one of the largest commission houses in that part of the world. A new department is to be created for the purpose of handling American electrical equipment, supplies, etc. Mr. Ruete's address is 128 Water Street, New York.

MR. CHARLES J. GLIDDEN, the chairman of the Boston touring committee of the American Automobile Association, who at present is abroad, will return in June and take up the active work of organizing the New England Division. Mr. Glidden will start his grand tour of the world by going from New York to St. Louis with the run from there to San Francisco. Before leaving New York, Mr. Glidden stated that he expected to bring Mr. Edge of Gordon-Bennett fame back with him to drive a Napier in the tour.

MR. H. WARD LEONARD, president of the company bearing his name, has resumed work, and we are very glad to state that he is entirely restored to health. He had to go into hospital on account of his eyes. He had considerable trouble with an attack of iritis, due to the results caused by arcing, and consequent upon tests he made in connection with making and breaking the circuit of several large motor starters built under his supervision at the Bronxville works. He is quite cured of this trouble and his eyes are in good condition.

MR. HERBERT LAWS WEBB has an interesting article in the London *Daily Mail* on the manner in which the telephone as a necessity in New York becomes a luxury in London. "British bankers will not use the telephone service. In America bankers are wholesale users of the telephone. In London there is not a hotel having telephone service in all the rooms. In New York the hotel which does not have the city telephone service in every room is the exception. The Metropolitan police refuse to use the telephone. The New York police have an elaborate system of their own and connection with the general system at every station. In New York for years past the police have managed all large processions by telephone. In London the police and the military manage processions by flag signalling! The broad difference between the American and the British public, and their respective authorities, is that the former welcome all devices aiming at saving time and increasing efficiency, while the latter resist them to the last ditch."

Educational.

HARVARD AND "TECH."—Advices from Boston of May 14 say: "Negotiations between the Institute of Technology and Harvard University looking toward their union have been formally opened by the Institute. It was announced to-day at the office of President Pritchett that a resolution of the corporation of the Institute had been formally transmitted to the corporation of Harvard. This resolution is as follows: "Voted, that the executive committee be required to ascertain whether any arrangement can be made with Harvard University for a combination of effort in technical education such as will substantially preserve the organization control, traditions and name of the Massachusetts Institute of Technology."

Trade Notes.

THE HAZARD MFG. COMPANY, of Wilkes Barre, Pa., has opened its own office and warehouse at 71 and 73 West Adams Street, Chicago, Ill.

MR. W. S. BROWN, New York representative of the Chase-Shawmut Company, Boston, has moved his offices to the Bancroft Building, 3 West Twenty-ninth street.

THE PERKINS MACHINE COMPANY, maker of power presses, has removed its main office from South Boston to its Warren plant at Warren, Mass. The company is receiving large orders for its machine from its German agents, Messrs. Schuchardt & Schutte, of Berlin.

THE F. BISSELL COMPANY, of Toledo, Ohio, has issued Bulletin No. 31 devoted to tape, solder, screws, insulating materials and carbon brushes. This bulletin becomes part of its new illustrated catalogue, and will be sent on request to any user of electrical goods.

GARTON-DANIELS COMPANY, Keokuk, Ia., has issued No. 40 catalogue, which embraces all details as to its full line of lightning arresters. This catalogue has already run in to more than one edition. It deserves the general circulation and demand it is enjoying. Businesss in these arresters for the first three months of 1904 shows a large increase over any previous period and the demand continues progressively.

H. T. PAISTE COMPANY, Philadelphia, Pa., is pushing its new P. K. "Pushin" attachment plug, and calls attention to its new principle of inserting without any backward or forward twisting of the cord. The inquiries and orders for it have already been most gratifying, beyond anything that was expected. This device is described and illustrated on page 1004 of this issue.

SELF-SOLDERING HEAT COILS.—Mr. Frank B. Cook, 240 W. Lake Street, Chicago, has an exclusive license to manufacture and sell all self-soldering heat-coils and other circuit protecting devices and apparatus covered by patents and applications for patents, as well as any devices of that kind, which may hereafter be invented by Charles A. Rolfe, or owned and controlled by the Rolfe Electric Company. All other licenses have been withdrawn.

HOLTZER-CABOT ELECTRIC COMPANY, Brookline, Mass., has just issued a new bulletin on motor generators, No. 302. It is somewhat larger and more comprehensive than the old bulletin, and covers its subject and its field most completely. An appendix of several pages has been added, which treats of the various forms of the telephone machinery of this class, showing the latest apparatus in this line. In fact, it is a most interesting catalogue and should be in great demand.

JAMES LEFFEL & COMPANY, Springfield, Ohio, have just issued a catalogue of 40 pages devoted to their steam engines, boilers and turbine water wheels. The engines and boilers are illustrated in full detail and descriptions are given of both classes of apparatus. Dimensions, sizes, etc., are also furnished, and from this catalogue the intending purchaser can obtain an excellent idea as to the best manner of satisfying his wants. The catalogue also illustrates the well known turbines made by this firm and the Leffel portable vertical engines, as well as Leffel upright engines and submerged tube boilers..

SIDE CUTTING PLIERS.—Mathias Klein & Sons, 87 and 89 West Van Buren Street, Chicago, are now making side cutting pliers in 6, 7 and 8 inch sizes, the 6-inch being a recent addition made to the line by general request. They make also a full line of climbers, splicing clamps, pliers, wire grips, pulley blocks, etc., and carry a general assortment of linemen's and construction men's requisites in such particulars. They also distribute "a good rule" which they will be pleased to send gratis to interested people.

ADAMS-BAGNALL ELECTRIC COMPANY, of Cleveland, Ohio, in its recent bulletins gives a number of illustrations and a variety of details as to its well-known arc lamps, for all classes of service. These lamps have been on the market for a number of years, and are standard features of the art. The company has paid special attention lately to the alternating current series type of lamp, with all the necessary parts and accessories, and its literature on the subject shows both the apparatus and the manner of connecting up the circuits, with particular attention to the regulator for the alternating constant current.

POP CONCERT AT THE ELECTRIC LIGHT CONVENTION.—A pop concert will be held at Symphony Hall, Boston, on the evening of May 25, during the convention of the National Electric Light Association. Mr. Geo. C. Ewing, Nernst Lamp Company, 501 Atlantic Ave., Boston, informs us that delegates may obtain free tickets by addressing him by mail or applying to him personally on their arrival at Boston. There will be approximately 600 seats at tables of 4 or 5 each, and it is proposed to make the evening a very enjoyable one for the delegates.

NEW BOILER FEED SYSTEM.—Frank E. Keyes, manager of the Refined Wood Company, of 20 Broad St., New York, has devised and patented an improved and very effective boiler feed system by which the water is purified, then put into the boiler under any pressure at a boiling point, without the use of pumps, injectors or inspirators, namely by gravity. It is claimed that the simplicity and the low cost of installation will appeal to all steam users. As the water is purified before going into the boiler, it is possible to run the boiler much longer without cleaning. A steady supply of clean hot water is insured, giving the greatest efficiency with the least amount of fuel.

KEYSTONE ELECTRIC COMPANY, Erie, Pa., has issued a handsome quarto catalogue devoted to its generators, motors, switchboards, panel boards, etc. It is a pamphlet of 40 pages, and is profusely illustrated, showing complete and in detail a large variety of excellent apparatus in these lines of production. A valuable part of the catalogue is that which gives detailed diagrams and dimensions of the machinery. We note a new type of brush holder, and the switchboards are also admirable types of that class of work. A section is devoted to the application of Keystone motors to machine tools, ventilating fans, etc., exemplifying a wide range of use for their power apparatus.

SLOTTING MACHINES.—The Newton Machine Tool Works, Philadelphia, Pa., in a recent catalogue, illustrate and describe a very complete line of slotting machines particularly adapted for use on electrical machinery and large engine work. These machines are made to he belt driven or motor driven, and range from 6 in. to 18 in. stroke. Each illustration is accompanied hy dimension tables. Other machines illustrated are a 40-in. gear cutting machine; an armor plate slotting machine; milling machine; cold saw cutting-off machines, etc. The illustrations are very clear and the machines have a very massive and substantial appearance.

THE STUART-HOWLAND COMPANY, Boston, Mass., reports a decided improvement in business with the opening of spring. It has recently secured several large orders, three of which are for shipment abroad. These, in addition to the ordinary business will keep its force very busy for some time to come. This company is located in the very heart of Boston, within one hundred feet of Summer Street and within four minutes' walk of the new terminal station. Its offices and warerooms are large, light, airy and especially convenient for handling goods at a minimum cost. It carries one of the largest and most complete lines of electrical goods to be found in the United States. The push, energy and up-to-date methods of this concern are too well known to the trade to require further comment.

CARBORUNDUM IN BUTTON MAKING.—Hitherto pearl buttons have been cut and drilled with steeled tools. An inventor named Louis W. Holub has devised a means of grinding them out of the raw mother-of-pearl by means of carborundum. The firm of Holub-Dusha Co., 1801-3 First Ave., New York, is now doing this. A little girl sits in front of the machine, feeding it, and just as fast as her little fingers can go the machine finishes the work, whether the button is 1/4 inch or three inches in diameter, whether the surface is to be straight, concave, convex, or the form of the button be that of round, oval, square, hexagon, triangular, or of any other form. The machine consists of a flat, slowly revolving, round, horizontal turn-table of about two feet in diameter. Near to its outer periphery is mounted a plurality of vertical button chucks, revolving rapidly around their own axes while slowly moving the turn-table. These chucks describe a circle of about 22 inches in diameter. Into this circle is mounted, eccentrically in relation to the chucks, a horizontally revolving carborundum wheel mounted on a vertical shaft. The diameter of the wheel is about 20 inches. As the carborundum wheel is 2 inches smaller in diameter than the circle described by the chucks, it comes in contact with but few of the buttons at a time, and thus leaves the rest of the chucks free for manipulation, such as placing the button therein, gripping it, taking out the finished product, and freeing it of dust, etc. When this so-called "merry-go-round" is in motion the carborundum wheel makes 5000 revolutions per minute, the chucks about 600, and the turn-table about 15 revolutions. When the chucks arrive before the little girl they are open and do not revolve around their own axes, but move with the turn-table. A button blank is placed therein. The chuck automatically grips it, begins to revolve with it, and brings it in contact with the lower side of the carborundum wheel. Terrific grinding takes place and in less than a second the top of the button is ground. When it has passed the grinding wheel the chuck ceases to revolve, it opens automatically, and the button is now under a suction tube that lifts it out of the chuck, taking with it every particle of dust, and the now clean and open chuck is once more before the little girl to receive a new blank to be ground. If the button should be convex or half round, then the lower or outer end of the carborundum wheel is dressed concave with a diamond. The wheel being intensely hard, it holds its shape for days, and it is re-dressed at a trifling cost.

ZINC.—In a very neat and illustrated pamphlet, recently issued by the Lanyon Zinc Company, "Two Stories of Zinc" are told, the first being the story of spelter. The various steps in the reduction of zinc from the ores are clearly described and a sketch is given of a day's work in a zinc smelter plant. The ore is first crushed and then treated in the calcining kilns where it is desulphurized, the zinc sulphide being changed into oxide and the sulphur passing off as sulphur dioxide. The temperature in these kilns is in the average 1700 degrees F., but is gradually increased as the period of calcination progresses. The zinc oxide is then mixed with finely ground coal and fairly coarse coke or coal in order to be reduced in the distillation furnace. In this step of the process zinc is treated in quite a different way from other metals. Zinc ore cannot be melted nor can any zinc be extracted by the usual methods of treating ores. Gold, for example, is placed in the furnace in company with the metals known as fluxes, which collect in the bottom of the furnace and late in the process are drawn off in the form of bullion containing the gold which is afterward refined and the metals separated. Zinc, when placed in contact with intense heat, is transformed into a vapor, and then recovered in condensers. This is done in the distillation furnace. The presence of any fluxing material in the smelting of zinc would be a positive detriment. On account of this method of distillation the losses of zinc during the treatment are high compared with other metals and average from 10 to 30 per cent. of the metallic contents of the ore. The Story of Sheet Zinc is next told in the pamphlet. The operation is one requiring skilled help and constant watching. The choicest of spelter is used. It is first melted in a huge pot and then poured into moulds and billets are cast. The billets are annealed and treated in the first or "roughing" rolls. They are then again annealed and treated in the finishing rolls. The last operation is the most delicate one of the process. The applications of sheet zinc have rapidly increased during the last 30 years. Among the more common uses of sheet zinc are the manufacture of metallic ceilings, stove boards, linings of refrigerators, and it is largely used in the zinc process for the extracting of gold from its ores. The use of small galvanic cells takes quite a large tonnage of this metal in the course of a year, since it has been demonstrated that batteries and rods made from sheet zinc are of a more satisfactory character than those which are cast. In recent years, the manufacture of nickel, copper and brass plated sheet zincs has grown rapidly, and they have entered into formidable competition with sheet brass and sheet copper.

Record of Electrical Patents.

UNITED STATES PATENTS ISSUED MAY 10, 1904.

[Conducted by Rosenbaum & Stockbridge, Patent Attys., 140 Nassau St., N. Y.]

759,237. CIRCUIT CHANGER; Charles C. Cadded, Cleveland, Ohio. App. filed June 15, 1903. Strip metal, spring contacts are actuated by a spreader carried by a lever and which moves in the space between the contacts.

759,276. INSULATOR FOR TELEGRAPH WIRES; Clayton Hobert, Philadelphia, Pa. App. filed April 10, 1903. A knob having grooves in the top arranged at various angles and a second knob or cover screwing down upon the first to hold a wire in one of the grooves.

759,280. TELEPHONE ATTACHMENT; Stephen C. Houghton, San Fancisco, Cal., and Frank M. Potter, Jr., Syracuse, N. Y. App. filed Dec. 30, 1903. (See page 987.)

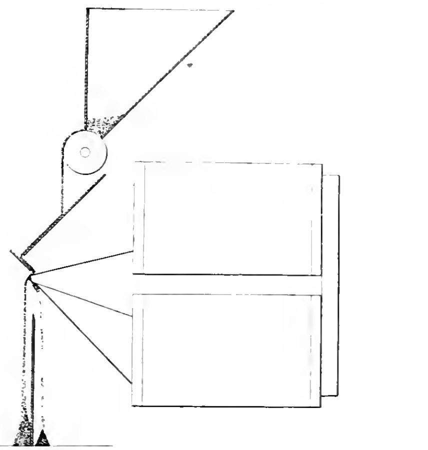
759,281. SIGNALING; Gustav A. Huber, Mounthope, N. Y. App. filed Jan. 9, 1904. General improvements in a magneto generator and selector.

759,286. ELECTRICITY METER; Martin Kallman, Berlin, Germany. App. filed Sept. 28, 1901. An armature deflected by the current has a to-and-fro motion which rotates a wheel in one direction giving it sufficient momentum at each impulse to keep the motion continuous between impulses.

759,316. TELEPHONE-RECEIVER; Walter C. Runge, London, Eng. App. filed Dec. 6, 1902. (See page 987.)

759,327. RAILWAY SWITCHING AND SIGNALING APPARATUS; John D. Taylor, Buffalo, N. Y. App. filed Oct. 25, 1901. Devices for preventing crosses on the wires of the system.

759,346. RAILWAY BLOCK SIGNAL SYSTEM; Winthrop M. Chapman, Newton, Mass. App. filed May 12, 1902. Various details of construction.



759,358.—Magnetic Separating Apparatus.

759,352. METER FOR MEASURING ELECTRICAL ENERGY; Louis P. Decombe, Paris, France. App. filed Nov. 26, 1901. The fine wire spool forms part of a system arranged in such a manner that the number of oscillations of a spool on a suitable axis is proportional to the energy consumed in the distribution.

759,358. MAGNETIC SEPARATING APPARATUS; Thomas A. Edison, Llewellyn Park, N. J. App. filed June 21, 1900. The separator consists essentially of an electro-magnet having extended tapering poles, one of which slightly overlaps the other to form a narrow gap between them whereby the magnetic particles will be attracted by the lines of force towards one of the poles and caused to fall into a compartment separate from that which receives the non-magnetic particles.

759,383. COMBINED SWITCH-SOCKET AND RESTORING-ANNUNCIATOR; Anton M. Knudson, Chicago, Ill. App. filed Oct. 13, 1900. (See page 987.)

759,385. RAILWAY SWITCH AND OPERATING MEANS THEREFOR; Lucius A. Lindsay, Strubbe McConnell and Clifford C. Hudson, Atlanta, Ga. App. filed Nov. 23, 1903. A circuit closing device actuated from the platform to energize magnets in the road bed for moving the switch tongue.

759,414. GROUND WIRE ATTACHMENT; Wilbert J. Bishop, Buffalo, N. Y. App. filed Sept. 4, 1902. A strap to embrace a pipe and carrying a roughened plate which bites into the pipe to make good contact.

759,426. ELECTRIC SOLDERING IRON; Sydney Evershed, London, Eng. App. filed Dec. 8, 1903. Details.

759,428. TELEPHONE-TRANSMITTER HOOD; Robert D. Fannon, Chicago, Ill. App. filed Oct. 29, 1901. (See page 987.)

759,431. ELECTRIC ACCUMULATOR; Ricardo Fortun and Eduardo Semprun, Madrid, Spain. App. filed Sept. 30, 1901. (See page 986.)

759,433. TROLLEY; Elmer E. Gillingham and Delancy E. Huntley, Wellston, Ohio. App. filed April 27, 1903. Two wheels mounted on a two-part frame, the members of which are hinged together, permitting the wheels to assume different vertical planes.

759,441. TELEPHONE TRANSMITTER; Alfred W. Hill, West Hoboken, N. J. App. filed Oct. 9, 1902. (See page 987.)

759,453. ELECTRIC RAILWAY; Timothy Mahoney, San Francisco, Cal. App. filed July 1, 1903. The two ends of the third rail are directly connected to the dynamo and means are provided for shunting the current from the rail through the car and back to the rail again.

759,464. ALARM SYSTEM; Felix McGloin, New York, N. Y. App. filed Dec 31, 1902. Improvements in non-interfering mechanism for alarm circuits.

759,492. TELEPHONE EXCHANGE; Clarence A. Anderson, Salina, Kan. App. filed Dec. 5, 1901. (See page 987.)

759,506. MEANS FOR AND METHOD OF SECURING LEAD-IN WIRES IN ELECTRIC LAMPS; John C. Entriken and Wm. S. Everett, Malvern, Pa. App. filed Jan. 21, 1904. That portion of the leading-in wires embedded in the glass is of platinum, as usual, but the remainder of the leading-in wire is of another and cheaper metal.

759,511. LIGHTING SYSTEM FOR LOCOMOTIVES; Ethelbert T. Ford, St. Louis, Mo. App. filed Dec. 21, 1903. A system of circuits and apparatus for operating the headlight and incandescent lights in the cab from the same dynamo and means whereby either circuit can be used alone.

759,543. ELECTRIC RAILWAY SIGNAL; Elwood W. McGuire, Richmond, Ind. App. filed Aug. 15, 1902. Details.

759,550. SECONDARY-BATTERY ELECTRODE; Charles J. Reed, Philadelphia, Pa. App. filed Jan. 16, 1901. (See page 986.)

759,586. ELECTRIC SWITCH; Henry C. Baer, New York, N. Y. App. filed Nov. 9, 1903. Details of a fixture switch.

759,600. ELECTRICAL SWITCH; Fay L. Faurote, Ann Arbor, Mich. App. filed March 14, 1903. A switch having a "combination" attachment which must first be properly set before the circuits can be closed.

759,615. BURGLAR ALARM; Arthur J. Kercher, Minneapolis, Minn. App. filed Oct. 9, 1903. An electro-static circuit closer which normally holds the circuit in an open condition by the attraction between two sets of electrically opposite plates.

759,632. SWITCH FOR INCANDESCENT LAMP SOCKETS; John D. Raymond, Chicago, Ill. App. filed Feb. 1, 1904. Details.

759,641. SIGNALING APPARATUS FOR TELEPHONE-SWITCHBOARDS; Edwin H. Smythe, Freeport, Ill. App. filed Jan. 26, 1903. (See page 987.)

759,650. MANUFACTURE OF SMALL INCANDESCENT LAMPS; Allen D. Whipple, Chicago, Ill. App. filed Dec. 5, 1903. (See page 988.)

759,652. RAILWAY SIGNAL; John W. Anderson, Jr., Woodland, Ill. App. filed Feb. 20, 1903. Details.

759,697. TELEPHONIC APPARATUS; Alfred Graham, London, Eng. App. filed Feb. 4, 1903. (See page 987.)

759,701. FACSIMILE TELEGRAPH APPARATUS; Ernst Karl Gruhn, Dresden, Germany. App. filed Nov. 21, 1902. An arrangement for preventing erroneous variations of the resistance, comprising a peculiar arrangement of a curved contact piece, bearing upon the resistance and having a certain relation to the motion of the controlling fulcrumed lever.

759,722. ELECTRIC HEATER OR RHEOSTAT; Max C. Krusger, Chicago, Ill. App. filed Oct. 6, 1902. A series of resistance plates superposed upon each other and with insulating material between them, all being clamped together.

759,740. BATTERY; Jay Noble and Edward L. Anderson, St. Louis, Mo. App. filed June 1, 1903. (See page 986.)

759,741. ELECTRIC BLOCK-SIGNALING AND TELEPHONING SYSTEM FOR RAILWAYS; Charles Goodman Otwell, and Ira Howard Melvin, Laurel, Del. App. filed Feb. 11, 1904. (See page 987.)

759,762. SIGNALING APPARATUS FOR TELEPHONE-SWITCHBOARDS; Edwin H. Smythe, Freeport, Ill. App. filed Sept. 14, 1903. (See page 987.)

759,767. RAIL SUPPORT; Louis Steinberger, New York, N. Y. App. filed Jan. 7, 1904. The rail chair is constructed to rock on its support to permit the rail to conform to pressures applied to it.

759,771. SIGNAL APPARATUS FOR TELEPHONE-SWITCHBOARDS; DeWitt C. Tanner, Chicago, Ill. App. filed March 27, 1902. (See page 987.)

759,787. CABLE HANGER; Frank E. Wey, Wheeling, W. Va. App. filed May 16, 1903. A special kind of strap.

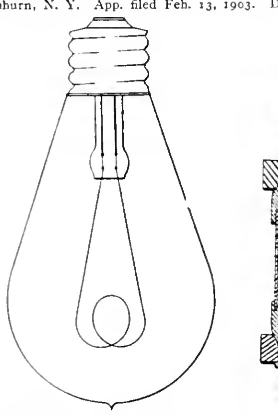
759,796. LIGHTNING ARRESTER; John C. Barclay, New York, N. Y. App. filed Sept. 9, 1903. A lightning arrester of special construction is combined with an inclosed fuse.

759,797. RHEOSTAT; John C. Barclay, New York, N. Y. App. filed Nov. 18, 1903. A telegraph rheostat comprising a variable resistance for insertion in an artificial line and a separate terminal connected to an intermediate point in such resistance and adapted for connection to a main line to compensate for battery resistance.

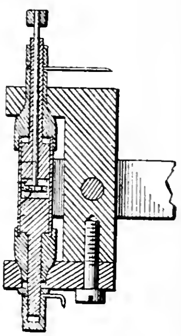
759,798. ELECTROLYTIC APPARATUS; Henry Spencer Blackmore, Mount Vernon, N. Y. App. filed July 22, 1903. (See page 986.)

759,799. ELECTROLYTIC APPARATUS; Henry Spencer Blackmore, Mount Vernon, N. Y. App. filed July 22, 1903. (See page 986.)

759,814. DOOR-LOCK-ACTUATED CIRCUIT BREAKER; Grayson G. Knapp, Auburn, N. Y. App. filed Feb. 13, 1903. Details.



759,506.—Means for and Method of Securing Lead-in Wires in Electric Lamps.



759,835.—Coherer.

759,825. WIRELESS TELEGRAPH APPARATUS; Joseph Murgas, Wilkesbarre, Pa. App. filed Oct. 2, 1903. In this system the message depends upon the character of the impulses, as the frequency, intensity, etc., rather than their time relation.

759,826. METHOD OF COMMUNICATING INTELLIGENCE BY WIRELESS TELEGRAPHY; Joseph Murgas, Wilkesbarre, Pa. App. filed Feb. 24, 1904. A modification of the preceding invention.

759,835. COHERER; Austin H. Stewart, Nashville, Tenn. App. filed Oct. 20, 1903. The agitator is within the tube and is actuated by a rod passing to the outside.

759,836. GENERATOR FOR TELEPHONE-CALLS; Ernest Hugo Strauss, Chicago, Ill. App. filed Nov. 17, 1902. (See page 987.)

CONTENTS.

SCOPE OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

It is probable that the range of topics touched upon by President Edgar this week at the Boston convention of the National Electric Light Association will surprise many who read his address. A great many important plans and topics are touched upon in a suggestive way, and a little thought will show that all of them fall legitimately within the scope of the body, whether regarded as a congress of large public service corporations or as the technical exponent of a great modern engineering industry. In fact, the opportunities and the responsibilities of the Association have grown, *pari passu*, with the wonderful expansion depicted by Mr. Edgar so briefly but so graphically; and if the Association does not go forward to larger usefulness, it must necessarily go back. This latter it will not do, if Mr. Edgar's fine address be any indication, or if we know aright the temper and quality of the men now administering the affairs of the Association and determining and shaping its policy.

Particularly do we like the broad gauge of Mr. Edgar's reference to the desirability of enjoying the hospitality of the Union Engineering Building in New York City, as headquarters for the Association; and his proposal to form a new class of members. In both respects this is an indication of that largeness of policy to which the growth and prosperity of such a body must always be due. It is well that the Association should thus put itself in touch with the other national engineering societies of the country, with consequent uplifting of its aims and motives. It is equally well that it should provide against the process of dessication and shriveling up that would inevitably attend a decline in even the mere numbers of membership. The drawing together of small lighting companies into a limited number of larger corporations is a fact and a sign of the times, and powerful associations have suffered from such a change, to the hurt of the public and to their own injury. Mr. Edgar's plan for keeping the membership full and alive with active men commends itself to our judgment, as doing what is needed to maintain the Association as a forum of lighting discussion and as an authoritative mouthpiece of the distribution art in general.

Such admirable papers and discussions as were presented this week are in themselves an argument for the wider membership that President Edgar advocates, and while we are glad to note the continuing share in the proceedings of many of the veterans, the happiest augury after all is the participation of new men so numerously. It is to them that the Association must look for its development and vigor in the years that are to come. Indeed, Mr. Edgar and the officers are to be heartily congratulated upon the attendance of the younger men in such numbers, and their keen interest in all that went on. It was notable that they read a large proportion of the papers and took a large part in the discussions—and hence in no slight degree was the brilliant success of a memorable convention achieved.

THE CONVENTION PAPERS.

The programme placed before the Boston National Electric Light Convention this week contained no fewer than 27 entries of papers and reports, including a "Question Box" which for full consideration would alone have taken up no small part of the entire time set for the disposal of the programme. By far the most valuable contributions to the proceedings are this "Question Box," and the hundred odd pages of "Wrinkles" which the indefatigable editor of this new department of the Association's work, Mr. Charles H. Williams, had gathered through correspondence with central station men. The amount of live information of direct practical value to central station men contained in the "Question Box" and "Wrinkles" should alone give a money value to the printed *Transactions* much in excess of the annual dues for membership in the Association. We believe, however, that somewhat more discrimination in the admittance of queries to the Question Box would conduce greatly to the permanent success of this valuable feature. At present too large a proportion of the questions are of a kind to which the querist could have found answer by reference to books which every electrical man worthy of serious consideration should have at hand, or relate to matters that from their scope or importance call for the services of a consulting engineer rather than free advice through this channel. Unless a change is made in this respect, we fear that those who would otherwise be glad to continue to supply answers to questions, will in time find their interest slackening. Of the other items on the programme, the report by Mr. Arthur Williams on "Sign and Decorative Lighting," and that by Mr. La Rue Vredenburgh on "Advertising Methods," will doubtless be found of keen interest by the more enterprising class of central station men. The time has certainly arrived when further considerable extension in central station supply will only come through the introduction of methods for extending business such as prevail in other branches of affairs; that is to say, every increase of business must depend largely upon methods for awakening the interest of possible customers and in subsequent solicitation of their trade in an intelligent manner.

To be properly prepared, however, to take full advantage of the possibilities of a campaign of publicity and individual solicitation, the central station man should know exactly every item which affects the price at which he can sell current profitably. Mr. Frank W. Frueauff, in a paper on "Office Methods and Accounting," has, in a well-written paper, set forth one aspect of this side of the situation, namely, that relating to a system of accounts whereby the central station manager may determine exactly the cost of electrical energy under any condition of service; and Mr. C. W. Humphrey, in an admirable report on "Lost and Unaccounted-for Current," pointed out the manner in which distribution losses may be segregated, thus enabling savings in this direction to be made, which in turn may permit of reductions in rates with consequent increase of business. It is notable that both of these eminently useful papers were written by members of the staff of the Denver (Col.) central station, where Mr. H. L. Doherty has, by the introduction of new methods, been enabled to increase enormously the output, following progressive reductions of rates doubtless fixed by analyses such as those described in the papers referred to, coupled with broadly conceived methods of publicity and personal solicitation of custom. Of the other papers, only two stand out with any prominence, namely, that of Mr. Eastman, upon which we comment below, and that of Messrs. Andrew and Wells, giving the result of an economy test of one of the 5,500-hp generating units in the New York Waterside Station. Indeed, the programme would have been very much strengthened by the absence of quite a third of the papers which it carries.

EFFECTS OF GROUNDING HIGH POTENTIAL LINES.

Mr. Eastman's N. E. L. A. paper upon this topic is singularly timely. So many high-potential polyphase systems with more or less underground conductor are now in use that questions of capacity, rarely serious on the older circuits, become of the first importance. How important they may be under common practical conditions Mr. Eastman's paper clearly shows. It must be remembered first, last and always, that the sources of trouble on high-voltage circuits are abnormal and not normal conditions. In the purely academic discussion of alternating currents the student, and even the average well-trained engineer, is too apt to get a fixed idea that the capacity and inductance of the line as such is of the first order of importance. On the contrary, the line is often of relatively small importance compared with the apparatus connected thereto. A modern high-voltage generator or transformer can furnish, when grounded, pretty high values of inductance, resistance and capacity according to the particular way in which it is constructed or misconnected. Accidents of a very simple kind are, moreover, capable of starting vicious surging, so that abnormal potentials are, as experience shows, rather common upon high-voltage alternating circuits. Every accident, every change of load even, produces disturbance of the potentials, generally trivial, but sometimes of serious magnitude. And where as in the admirable four-wire, three-phase system there is a neutral conductor, its potential relations may be seriously disturbed even while the voltages of the system remain in fairly close accordance.

This case is the one particularly investigated by Mr. Eastman, who has worked out the potential relations between ground and neutral under various hypotheses as to the resistance, reactance and condensance of grounds on one phase wire. The upshot of the matter is that under certain conditions which may occur in practice, the voltage between neutral and earth may rise to dangerously large figures, which, particularly in underground distributions, would be likely to lead to serious trouble. It is, we believe, the common experience of those operating high-voltage alternating circuits that at times there become evident potentials altogether greater than any which normally belong to the system. At an earlier stage of the game these were charged up to "static," which meant anything and everything from lightning to a leaky switch base. Later there was a disposition to lay everything to resonance, which was nearer the mark, but somewhat vague. Resonance in the form of resonance with the fundamental frequency is fortunately exceedingly rare. In its minor varieties it is, of course, common, but it is well to remember that all abnormal potentials are not due to resonance. At all events, large disturbances of potential may, on polyphase systems, result from so simple a thing as a ground, and when these are averted their serious secondary effects are eliminated also. It therefore is of no small importance to understand the conditions under which abnormal potentials are liable to be encountered.

It is certain at least that some unpleasant contingencies may be escaped by so simple a device as grounding the neutral conductor in a three-phase system. The effect of such grounding is to give a stable relation between the working voltages involved so far as accidental rise of potential is concerned. Once grounded, the neutral holds at earth potential and one knows exactly what he is dealing with. Of course, a low-resistance ground on the neutral means the possibility of a ferocious short-circuit if there should occur a bad ground on one of the phase wires. On aerial circuits this possibility may sometimes outweigh the advantage to be gained by a grounded neutral, but on underground circuits where any sort of an active ground is likely to put a cable out of commission, the severity of a short-circuit is of small account compared with an increased chance of averting one entirely. It would be interesting to figure out all the various sorts of abnormal potentials that can result from the grounding of lines and apparatus, but it would be a formidable task, and Mr. Eastman should certainly be heartily thanked for bringing to notice a single important case. Obviously, the same conditions which he discusses may exist in the case of secondary mains, causing serious danger of breakdowns in inside fixtures and connections, and the same remedy will prove effective. It is the old question of grounding the neutral in a three-wire system over again. So far as alternating distributions are concerned, there can be but one answer on the score merely of safety. A grounded secondary system is so essential to safety that it may perhaps be unnecessary to recommend it on other grounds. The best evidence of the success of the policy of grounding the primary neutral is the comparative immunity of the great Chicago system from troubles which have not infrequently been serious elsewhere.

Alternating-Current Wave-Forms.

At the annual meeting of the American Institute of Electrical Engineers, an interesting paper was presented by Mr. G. H. Rowe on the variations of wave form of e.m.f. on a long-distance transmission system. The system was that of the Standard Electric Company in California, extending from the power house in the hills at Electra to San Francisco, 153 miles away, with taps at a number of stations en route, and with shorter parallel lines and branches. The system was supplied with power at Electra by a plurality of Stanley inductor three-phase, 2-kilovolt, 60-cycle generators in parallel. The e.m.f. was supplied not only by these machines, but also by a number of synchronous motors operating at various places on the system. The voltage on the long-distance lines was in the neighborhood of 40 kilovolts. A Blondel oscillograph was arranged to take photographic oscillograms of the voltage on the system, at successive intervals of about half an hour, for ten or twelve hours together. The oscillograph records were not taken simultaneously over the system, or on the same day at the different stations. The oscillograph seems to have been sent from station to station, and to have been used at different dates, during a period of ten weeks. The oscillograms were taken at the Electra power house and also at San José, Stanford and San Francisco, three stations near the distant end of the system. An additional three-phase—two-phase transformer was in circuit at Stanford, which may have had some special influence there. Omitting Stanford, the wave forms at San José, 113 miles from Electra, and at San Francisco, 153 miles from Electra, fairly resemble each other; so that the discussion is advantageously narrowed, without much loss of generality, by considering only the e.m.f. waves at Electra, the generating end, and at San Francisco, the extreme terminal of the system.

Although the oscillograms were not taken on the same day, yet the evidence favors the belief that there exists a considerable difference in wave form between these two ends of the system at certain times of the day, particularly during the times of heavier load. The e.m.f. waves at Electra may be described as being approximations to sine waves, with a hump or dissymmetry, sometimes on one side of the maximum and sometimes on the other. At San Francisco, the e.m.f. wave is shown to have varied from a nearly sinusoidal form, at 1:30 A.M., when there may have been relatively little load, to almost a double-peaked wave at 6:20 P.M., when the local load may have been relatively heavy. Assuming, however, that the oscillograms, actually taken on different days, are fairly indicative of what occurred simultaneously at the ends of the system on either occasion, it would seem that a distortion in e.m.f. occurred at the distant end of the system, which might almost amount to the production of a double-peaked wave, or a camel-backed wave; while at the same time a slight dissymmetry occurred in the dromedary-backed wave at the generating end. In other words, it seems possible to have dromedary waves of e.m.f. at the generating end of an extended transmission system, and to have camel waves, at the same time, at the other end of the system.

The analysis of the waves, as given in the paper, indicate 10 per cent. harmonics of triple-frequency, and 8 per cent. harmonics of quintuple frequency. Such magnitudes of harmonics are readily capable of producing either camel waves or sharply-peaked dromedary waves, according to their respective phase displacements relatively to the fundamental. It seems evident that if the load on the system were simply incandescent lighting—supplied through transformers—that is to say, if there were no motors connected with the system, the e.m.f. wave form would be substantially the same all over the system, for any reasonable approximation to a sine wave delivered by the alternator. A very kinky wave at the generator, bristling with harmonics, might set up resonant effects at the distant end, with some harmonics, while other less favored harmonics might be smoothed out; but a sine wave at the sending end would establish a sine wave to the last lamp on the system, through the last transformer, except for the small influence of drop of pressure in conductors. The current waves, however, might be very much distorted at light loads, owing to hysteresis in the transformers. At full load this disturbance would be reduced. The variations in current wave form between generator and distant ends would tend to be more marked than the variations in the e.m.f. waves, owing to the influence of charging currents. With capacities at work current waves are always more liable to vary than e.m.f. waves from a single source.

Every motor, and particularly every synchronous motor, connected with a system, is virtually a new generator with its own e.m.f. waves and ripples, added to the system. If the system of transmission conductors had no appreciable resistance, the e.m.f. wave would be the same all over the system. The presence of distributed resistance, inductance and capacity in the transmission lines favors the existence of local ripples due to the various separate generators, whether those generators are supplying power in bulk or are absorbing power in bulk. It is common to find a synchronous motor under load absorbing a large amount of power from the system at its fundamental frequency of 60 cycles per second, and yet generating, and delivering in return, a small amount of power to the system at harmonic frequencies, such as 180 or 300 cycles per second. It seems that this Institute paper contains valuable evidence as to the influence of motor e.m.f's in locally modifying the voltage wave form in a transmission system containing considerable distributed resistance and capacity, as well as some inductance.

Alternating-Current Wave-Form Analysis.

In fitting sequel to the preceding topic is an article in this issue on page 1023, by Prof. S. M. Kintner, giving the details of one of the most popular methods of harmonic analysis, or the decomposition of an irregular wave form into its component fundamental sine wave and multiple frequency sine ripples. There are a number of methods of effecting such analysis, and there are also, in fact, several kinds of machines for effecting the analysis mechanically. Prof. Kintner supplies a number of convenient tables, of three-digit accuracy, for effecting the analysis up to the seventeenth frequency harmonic inclusive. He suggests that these can be kept on manifolded or mimiographed forms, with the blank columns ready for their figures. A yet simpler equivalent plan would, of course, be to retain the tables on single columns of paper, or celluloid, for use in juxtaposition with the sheets used in computation, so that one and the same column might serve for an indefinite number of successive analyses. It seems likely that the directions and tables given in the article may be useful to many engineers who may have wave forms they wish to analyze and yet have no mechanical analyzers, such machines being rare and expensive.

Cost of Steam Electrical Generating Plants.

At the recent Washington meeting of the American Cotton Manufacturers' Association, Prof. R. C. Carpenter, of Cornell University, presented a paper entitled "The Cost of Power," from which we extract the portion giving data as to the cost of steam plants.

Table I gives current prices on the basis of a 1,000-hp plant, of various types of steam boilers. The tables following give, on the same basis, the cost of steam engines and electrical generators, together with data as to depreciation, etc.

TABLE I.—COST PER HORSE-POWER OF 1,000-HP BOILER PLANT.

Kind of boiler.	Price per B. H. P. erected.	Depreciation. Per cent.	Cost of brick work.	Total cost of boiler plant and building.	Annual charges, interest and depreciation.
A Horizontal Water Tube Forged Steel Headers	$14.00	5	$2.00	$24.25	$2.42
B Horizontal Water Tube Cast Steel Headers	13.00	8	2.50	23.25	2.59
C Horizontal Water Tube Cast Iron Headers	12.00	10	2.50	22.25	2.72
D Horizontal Water Tube Flat Stayed Head	12.00	10	2.50	22.25	2.82
E Horizontal Water Tube Curved Steel Tubes	9.00	15	3.00	19.75	2.91
F Vertical Water Tube Straight Steel Tubes	9.00	12	3.00	19.75	2.43
G Horizontal Fire Tube Plain Tubular	9.00	15	4.00	18.75	2.46
H Vertical Fire Tube	6.50	20	1.50	16.75	2.64

TABLE II.—COST PER HORSE-POWER OF 1,000-HP ENGINE PLANT.

Kind of engine.	No. of cylinders.	Price per H. P.	Price of condensers.	Price of piping and foundations.	Total cost per engine horse-power.
A Simple Slide Valve, Non-cond.	1	$5.00	....	$5.00	$10.00
B Comp. Slide Valve, Non-cond.	2	8.00	....	7.00	15.00
C Comp. Slide Valve, Cond.	2	8.00	$2.00	8.00	18.00
D Simple Corliss, Non-cond.	1	8.00	....	6.50	14.50
E Compound Corliss, Cond.	2	12.00	2.00	7.00	27.00
F Triple Corliss, Cond.	3	16.00	2.00	7.00	25.00
Electric Generator for D, E and F.		12.00	....	....	....
Steam Turbine with Elec. Generator		30.00	3.00	5.00	38.00

TABLE III.—TOTAL COST OF 1,000-HP PLANT.

Kind of Engine.	Total cost of engines and boilers. F type.	Annual cost of both engines and boilers dep. & in.	Tons of coal per year for one engine H.P., 3000 H.P.	Lubricants.	Labor engine and boiler.	Total cost of power, coal, at $2.00 per ton. Per engine H.P. 1 year.
A Simple Slide Valve, Non-cond.	$29.75	$4.03	6,750	$1.02	$5.00	$23.53
B Comp. Slide Valve, Non-cond.	31.50	4.38	5,660	1.25	4.50	21.45
C Comp. Slide Calve, Cond.	29.80	4.26	4,050	1.25	3.80	17.41
D Simple Corliss, Non-cond.	32.25	3.84	6,075	1.00	4.70	21.00
E Comp. Corliss, Cond.	30.87	3.76	3,375	1.25	3.50	16.25
F Triple Corliss, Comp.	34.25	4.28	3,110	1.50	4.00	16.00
Elec. Gen. for D, E or F.						
St'm Turb. with Elec. Gen. C.	47.87	5.91	3.375	.50	3.50	16.45

TABLE IV.—DEPRECIATION AND OTHER ENGINE PLANT DATA.

Kind of Engine.	Depreciation. Per cent.	Steam per H. P. Ordinary engine.	Steam per H. P. Best record.	Boiler H. P. required per 1000 engine H. P.	Annual charges dep. and int., engine only.
A Simple Slide Valve, Non-cond.	15	33	30	1,000	$1.60
B Compound Slide Valve, Non-cond.	15	25	22	840	2.20
C Compound Slide Valve, Cond.	15	16	14	600	2.80
D Simple Corliss, Non-cond.	10	30	27	900	1.65
E Compound Corliss, Cond.	10	15	12	500	2.55
F Triple Corliss, Cond.	10	14	10	466	3.15
Electric Generator for D, E or F.	10				1.80
Steam Turbine with Elec. Generator	10	15		500	4.70

The final results in Table III show the total cost of power per year, including labor, lubricants and coal at $2 per ton. The cost of steam power for several classes of machinery are taken into consideration as varying from $16 per year with the compound Corliss engine, to $24 per year when the simple slide-valve non-condensing engine is used. The table shows that best results are obtained commercially with the compound Corliss engine, although the steam turbine with electric generator is a close second when the results are based upon the cost per engine horse-power per year.

Interest is assumed at 5 per cent., and the cost of buildings not included. In calculating coal it has been assumed that one boiler horse-power required 4.5 pounds per hour, giving an evaporation of 6.66 pounds of water per pound of coal. In computing labor it is assuming that one man is needed in the boiler house for each 200 boiler hp and that the cost in engine room is $2 per hp-year.

Economizers are not considered. The present cost, allowing 5 sq. ft. of surface per horse-power, is about $6 per hp erected. To obtain the total cost, there should be added for feed pumps, heaters and boiler house piping $1.25; for brick chimney $3.50; for boiler house $4; except for G and H add $5. Mechanical stokers are not considered. The present cost of these is $3.50 to $4.50 per boiler hp. One year is assumed to include 3,000 hours. No charge is made for coal used in banking fires.

Census Report on U. S. Telegraph Systems.

The Director of the Census has issued a preliminary report on the commercial telegraph systems of the United States for the year ending December 31, 1902. The report includes only commercial telegraph companies owned and operated within the United States, which were in operation during any portion of the year, no statistics being given for foreign telegraph companies operating in the United States.

Number of companies	21
Common stock: (1)	
Authorized, par value	$104,383,075
Issued, par value	99,870,225
Gross income	37,552,450
Total expense	28,490,219
Dividends and interest on bonds	6,084,919
Net surplus	2,977,312
Miles of wire operated	1,248,602
Number of messages sent during 1902	90,844,789
Number of telegraph offices	27,352
Batteries in offices:	
Primary—Number of cells	634,491
Storage—Number of cells	19,639

(1) Exclusive of the capitalization of the Postal-Telegraph Cable Company, which was reported as $100,000.

The final report will contain an analysis of the above totals and present statistics for other phases of the industry.

Anniversary of the Telegraph.

The sixtieth anniversary of the sending of the first telegraph message (from Baltimore to Washington) was celebrated by the Postal Telegraph Company at its building in New York City, on May 24. This date also was the tenth anniversary of the opening of the company's building at 253 Broadway. In commemoration of these two events Mr. Clarence H. Mackay, president of the Postal Company, entertained at dinner at the Hardware Club the company's general and assistant superintendents from all sections of the country, including California and Texas. There were 100 at the dinner, the other guests being the officers of the company, including Col. A. B. Chandler, chairman of the directors; George G. Ward, general manager of the Commercial Cable Company; Charles R. Hosmer, vice-president of the Commercial Cable Company; W. H. Baker, general manager of the Postal Telegraph Cable Company; E. C. Bradley and C. C. Adams, vice-presidents; E. C. Platt, treasurer; Ford Huntington, treasurer of the New York Telephone Company.

President Mackay welcomed his guests in a speech in which he said that Prof. Morse lit the torch which now flashes the sparks of intelligence, progress and civilization over the continents and under the seas.

Speeches were also made by Col. A. B. Chandler, Vice-President George G. Ward, of the Commercial Cable Company, and Vice-President Baker, of the Postal Telegraph Company.

Handsome menus were presented as souvenirs. The cover had a picture of the Postal Telegraph Building on the front and the Commercial Cable Building on the back. Inside was a picture of Prof. Morse and the playbill of "The County Chairman," which the party saw on Monday night as the guests of Mr. Mackay.

The Largest Electric Water Power Station in New Hampshire.—I.

MOSES G. FARMER said that Garvin's Falls would one day supply light and power in Manchester, N. H., fourteen miles distant, when he was in that city many years ago. This prophecy has now come true. During 1902 an electric station was built at Garvin's Falls, and energy from the falling water began to be transmitted to Manchester at about 12,000 volts pressure, as described in the ELECTRICAL WORLD AND ENGINEER of January 17, 1903. At that time the capacity of the electric station was 1,300 kw, and the water was made available at the station by a previously existing dam and canal.

This dam is decades, and the canal perhaps a century, old. In that portion of its bed opposite to the canal, the Merrimac River passes over a series of rapids or low falls, and the old canal appears to have been built at first as an aid to navigation between Concord, New Hampshire and Boston. In 1793 a charter was granted for the construction of a canal between the Charles River and Lowell, on the Merrimac River. About the same time the Bow Lake and Canal Company secured a charter with the right to perfect navigation south of Concord on the Merrimac River. This stream passes over a number of falls and rapids between Concord and Lowell and the remains of an old canal can be traced at a number of such points along the river. Just when the canal through which boats passed around Garvin's Falls came into use cannot now be stated, but Hayward's *New England Gazetteer,* published by John Hayward at Boston, in 1839, mentions the canal as an important waterway for boats coming south from Concord.

The railways having put an end to water traffic on the Merrimac, attention was turned to Garvin's Falls as a source of power, and a stone dam was completed there near the upper end of the old canal, on September 5, 1859. The final builder of this dam, being in a hurry to complete it, dumped a large amount of loose rock in to form the central portion, after the builder of the end sections had been called to Washington to superintend work on a new government building there. As might have been expected, the dam failed in the freshets of the following year, about 200 ft. of the central portion going out on March 5, 1860. The dam remained in this partly

FIG. 1.—OLD DAM AND CANAL, GARVIN'S FALLS.

ruined condition for nearly a score of years, or until 1879, when its owners filled up the central gap with a timber crib and stone section just in time to prevent the lapse of their flowage rights.

At the time when a location was being sought for some of the large cotton mills now at Lowell, the site at Garvin's Falls was considered, but finally rejected. Thus the small tower of Bow, where the falls are located, escaped the fate of being a large city. From the rebuilding of the dam in 1879 down to about 1890 the water power at Garvin's Falls appears to have been used to some extent and during a portion of the time for local manufacturing purposes. Some time after the latter date an electric lighting station of small capacity was built there for comparatively nearby service, and this lighting plant remained until after the property passed into the hands of the Manchester Traction, Light & Power Company, near the close of the century. From all this it appears that although these falls had been close to places of considerable population for a hundred years, and a dam and canal had been maintained for power purposes during forty years, yet most of the energy of the water had run to waste during these long periods. It remained for electrical transmission, answering the demands of the largest city in the State, to bring Garvin's Falls effectively into the service of men.

Shortly after the purchase of the Garvin's Falls property by the Manchester company, the new electric station of 1,300-kw capacity, above named, was built, and the transmission at 12,000 volts to that city begun. This new station relied for power on the patched dam of 1859, and on the transportation canal that ran back into the eighteenth century for its origin. Though the Manchester company had

FIG. 2.—OLD AND NEW CANAL IN USE TOGETHER, GARVIN'S FALLS.

the right to utilize the entire flow of the Merrimac it was impossible to do so, because the ancient canal originally dug for small boats could not carry the whole river. Furthermore, the composite dam was of uncertain strength. The plan of the Manchester company was, therefore, from the start to build a new dam and dig a canal that would carry all the available water at times of moderate flow. Meantime, as the demands for light and power in Manchester were pressing, an incomplete station was built at the falls and as much generating equipment was installed as the water coming down the old canal would operate. For half a year work has been under way on the new dam and canal, and on the extension of the power house. This work has now reached a stage that gives promise of the early delivery in Manchester of all the power that a 28-ft. fall in the Merrimac will yield.

The construction now under way at Garvin's Falls contemplates an ultimate station capacity of 3,900 kw or 5,200 hp in electric generators. This capacity is to be made up of six three-phase, 60-cycle alternators, each rated at 650 kw and 12,000 volts. Three 39-in. turbine wheels mounted on the same horizontal shaft are direct-connected to each generator and drive it at 180 r.p.m. The rating of each group of three wheels is 1,000 hp. As the station at Garvin's Falls now stands, with 1,300-kw capacity in electric generators, it is the largest electric water power plant in New Hampshire. When the extensions now under way are completed and the station capacity is raised to 3,900 kw, it seems improbable that any electric water power plant in the State will equal it for at least many years to come. This conclusion is supported by the fact that the Merrimac is much the largest river in New Hampshire, and that the fall at Garvin is greater that that at any other point on the river in that State, save the one at Manchester, which is utilized by a great manufacturing corporation located there.

The Merrimac is not a great river, being only 110 miles long from its head, at Franklin, N. H., to its mouth at Newburyport, Mass., neither is its elevation exceptional, for the head waters at Franklin are only 269 ft. above sea level. Nevertheless, this comparatively small river probably turns more spindles than any other stream in the United States or even in the world. This is due to the fact that three of the four largest powers on the river, those at Manchester, Lowell and Lawrence, are mainly devoted to the manufacture of cotton goods. Considering its length, the drainage area of the Merrimac is exceptional, being 4,864 square miles. At Lawrence, 28 miles from the mouth of the river, the drainage area is 4,553 square miles, and the mean annual discharge of water from 1890 to 1897, inclusive, ranged between 4,850 and 9,373 ft. per second. Above

Garvin's Falls, which is 83 miles from the mouth of the Merrimac, the drainage area is 2,400 square miles, and it is estimated that the head of 28 ft. there will yield at least 5,000 hp during nine months of each year. During the great freshet of March 2, 1896, the largest in the history of the river, it is estimated that the discharge at Garvin's Falls rose to 72,000 cu. ft. per second. At Lawrence the fall of the Merrimac is 29 ft., and at Manchester it is 52 ft., and these are the only other two points on the river where the height of the fall at Garvin's is approached.

The old dam at Garvin's Falls is located about 1,240 ft. up stream from the power station, and water formerly came down to the station through the old canal of that length. Between abutments the old dam, built in 1859, and partially rebuilt in 1879, has a length of 454 ft. The old canal is a rough excavation of irregular cross section, and has an overflow wall of timber and stone for a part of its length on the side next to the river. The new dam is being built across the river at a point approximately 500 ft. up stream from the power station, and something more than 700 ft. below the old dam. In length the new dam is about 550 ft. between the abutments and these latter, together with their core walls and the head gate wall, extend up into the banks about 160 ft. on the canal side and 80 ft. on the opposite side of the river, beyond the central portion of the dam. On the right-hand side of the river, at one end of the new dam, the new canal begins and in its course to the power house it

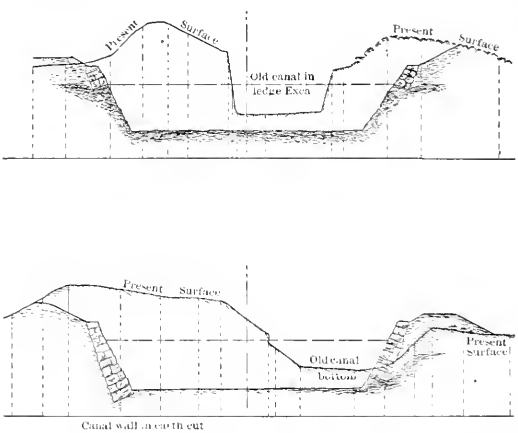

FIG. 3.—CANAL PROFILES.

overlaps substantially the entire site of the lower 500 ft. in the length of the old canal. The new site selected for the dam not only afforded a natural rock foundation with comparatively little excavation, but also shortened the required length of canal by more than 700 ft.

Of the total length of about 550 ft. in the central portion of the dam, 70 ft. at the left-hand end has a crest 2 ft. above that of the remainder in elevation. For its entire length the dam rests on the natural ledge in the bed and banks of the river. In general outline the dam is straight and its height above the bedrock varies from about 10 to as much as 25 ft. between the elevations of heel and crest. A notable feature of the dam is its width up and down stream, which amounts to as much as 31 ft. from heel to toe in the part that is 25 ft. in elevation from heel to crest. The portion of the dam between the abutments is of stone masonry laid in mortar of Portland cement and sand. Ashlar masonry is used on the crest and down-stream face of the dam, and rubble masonry for its up-stream face and core. Of that portion of the dam between the abutments three sections have been completed, one section adjoining each abutment and one about mid stream, and if the weather is favorable it is expected that the entire dam will be completed during the winter. Both of the dam abutments, including the head gate wall at the entrance to the canal on the right-hand bank, are practically finished. The right and left bank abutments are formed of concrete and faced with ashlar masonry, and the head gate walls are built entirely of concrete.

When the new canal is considered, the importance of the change made in the water power development at Garvin's Falls becomes evident. The striking feature of the new canal is its great increase in area of cross-section over that of the old. It is hard to state accurately just what is the cross-section of the old canal, since this varies materially in the course of its length, but it may be put at approximately 264 sq. ft. for at least a part of its course, up to the

FIG. 4.—HEAD GATES, NEW CANAL, GARVIN'S FALLS.

top of its banks. Compared with this, the area of cross-section for the new canal to the top of its banks is 1,260 sq. ft. at the entrance to the forebay. Up to its flow line the canal has a cross-section of 750 sq. ft. before it widens into the forebay. The new canal has been excavated partly in earth and partly in ledge, and some filling has been necessary along its banks. In all cases where the canal wall or any part of it is in earth, this wall is of concrete or stone masonry. Before entering the forebay the canal at its flow line, which corresponds in elevation with the top of the dam in its mid-stream section, has a width of 74 ft., and this flow line is 13 ft. above the canal floor. In its course of about 500 ft. between the head gates and the forebay the level of the canal floor drops one foot.

The floor of the forebay gradually drops to a level four feet below that of the canal at the point of entry. This gives the water in the forebay, when just up to the level of the top of the dam at its

FIG. 5.—CANAL FROM HEAD GATES, GARVIN'S FALLS.

middle section, a depth of 17 ft. At the river side of the forebay is an overflow wall 90 ft. long with a crest that is 2 ft. above that of the river section of the dam. At the rack the width of the forebay is increased to 134.5 ft., and 80 ft. of this rack length represents the new addition. In vertical height the rack is 20 ft., and its top is 3 ft. above the crest of the river section of the dam. In the forebay wall near the river end of the rack are the waste and flush gates. The entire floor of the forebay was excavated in the ledge of the river bank.

The head wall of the forebay forms also one side of the wheel room at the power station. This station thus sets directly across the lower end of the canal, and is connected with the river by a short tail race. On the top of this head wall of the forebay, which is of stone masonry and rises to an elevation 8.5 ft. above the crest of the river section of the dam, there is a pent house containing electric motors that operate the gates of the several wheels. When completed the power station will have an outside width including the head forebay wall of 67 ft., and an outside length of 149.75 ft., at the foundation level. Of this total length that part of the station built in 1901 forms 65.5 ft. The wheel room from the outside of the head wall of the forebay to the wall that separates the wheel and generator rooms is 33.5 ft. wide, has less elevation than the remainder of the power station, and is covered by a nearly flat roof. Inside of the generator room the width is 30 ft. and the length about 146 ft. Above the stone foundations the station walls are of brick and the parallel walls on the two longer sides are each 24 in. thick to an elevation of 20 ft. above the floor of the generator room, at which elevation their thickness shrinks to 9 in., giving a shelf 15 in. wide to support the traveling crane. Beneath the generator room there is a stone foundation resting on bedrock and consisting of arches, and this foundation is pierced by seven arched openings, which connect an open space beneath the entire wheel room with the tail race.

The floor of the wheel room is of spruce plank laid on steel I-beams that rest on the head wall of the forebay at one end, and on the arches beneath the generator room at the other end. These I-beams also support the wheel cases, which are hung between them. Seven steel wheel cases pierce the forebay wall and extend into the wheel room. Each of six of these cases is 12 ft. in diameter and contains three 39-in. horizontal turbine wheels. The seventh case is 5 ft. in diameter and contains two turbines of 12 in. diameter each. From

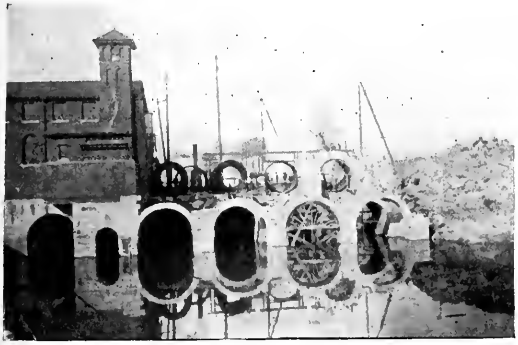

FIG. 6.—NEW FOUNDATIONS FOR ADDITION TO GARVIN'S FALLS POWER STATION.

each wheel case two draft tubes extend down to a level below that of the tail water. From each set of wheels the horizontal shaft extends through a water-tight bearing set in the wall that separates the wheel room from the generator room, and is direct-coupled to that of a generator or exciter. The center of the shaft of each set of main wheels and of their generator is 10.5 ft. below the crest of the dam at its river section, and 17.5 ft. above the ordinary level of the tail water.

In the generator room the concrete floor is supported by the stone arches beneath, and rests in part on I-beams that span the spaces between them. The floor is finished with a layer of Portland cement mortar 2 in. thick. As the floor level in the generator room is 15 ft below the crest of the dam at its river section, and 5.24 ft. below the level reached by the back water in the great freshet of March 2, 1896, the highest on record, both the floor and the walls were made watertight up to a level 2 ft. higher than that reached by the back water during the freshet just named. With this construction the power station may continue in operation when high water backs up about its outside walls and in the wheel room to an elevation more than 7 ft. above that of the floor in the generator room. As the entrance to the station, at the end more distant from the river, has an elevation as great as that of the dam crest, and about 10 ft. above the freshet level no water can enter there.

Beneath each of the 650-kw alternators in the generator room there is a pit 12 ft. long, 6 ft. 2 in. wide and 2.5 ft. deep beneath the floor level. Each of these pits is connected by iron pipe with a drain tank set beneath the floor level, and water is removed from this tank by means of a small centrifugal pump driven by a motor. From each or the pits beneath the main generators and also from each of the two exciters, conduits are laid to the switchboard bay. This bay is located about midway on that side of the generator room opposite to the wheel room. Exclusive of the switchboard bay the total width of the generator room is only 30 ft., and of this width the row of generators takes up 17.5 ft., leaving only 12.5 ft. between

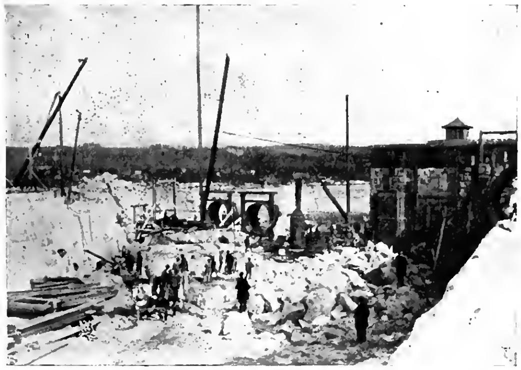

FIG. 7.—LAYING FOUNDATIONS FOR ADDITION TO POWER HOUSE.

the outer end of a generator bearing and the wall. The switchboard bay juts out on the tail race side of the generator room with a length of 33 ft. and a depth of 6.5 ft., above the foundations. Inside the switchboard bay measures 7.5 ft. wide and 26 ft. long at the floor level, and the lowest point on the inside of its slanting roof is 16.5 ft. above the floor. The switchboard sets in this bay so that its face is nearly in line with the inside surface of the main wall of the generator room, and this location leaves ample room for access to the rear of the board, which is reached through a door at one end. Beneath the switchboard and running its entire length is a trench in the concrete floor 10 in. wide and 12 in. deep, where the conduits carrying cables from the generators and exciters terminate. In the side wall of the switchboard bay at an elevation above the top of the board a row of slate slabs are set in the brickwork, and these slabs are pierced by circular openings through which the bare conductors pass that transmit the energy of the water power plant to the substation in Manchester, 14 miles away.

As matters stood at Garvin's Falls early in 1903, before construc-

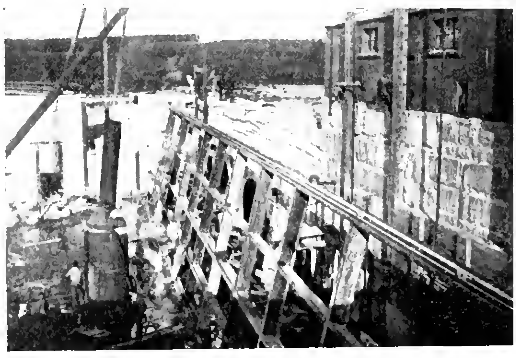

FIG. 8—RACK AND FOUNDATION FOR ADDITION TO GARVIN'S FALLS POWER STATION.

tion on the extension of the power plant was started, it was necessary to discontinue the operation of the station altogether, while the new canal and the foundation for the addition to the station were being built. The 1,300 kw of generator capacity in the incomplete station could be shut down with the least loss during the summer months, and the general contract for the new dam, canal and extension of the power station was accordingly closed on June 5, 1903, with the provision that the new canal, station foundations and the deepening of the tail race were to be first completed. This plan has been carried out, water was let into the new canal in November of the present year, and the older portion of the power station with its two 650-kw generators is now in regular operation. It remains to complete the new dam and the addition to the station above the foundations, and to remove a portion at least of the old dam of 1859. This old dam and the upper section of the old canal are still in use to divert and deliver water to the new canal. The upper 700 ft. in the length of the old canal brings water down to the head gates of the new canal, and will continue to do so until the new dam is completed. By this use of the old canal it is possible to maintain a dry river bed for work on the new dam, while the new canal is in use. The work of construction can now go on without interfering with the operation of the older part of the power station, and it is expected that the entire development will be completed during the first half of 1904.

The Manchester Traction, Light & Power Company, the owner of the electric light, power and traction systems in that city, owns also the entire water power rights and developments at Garvin's Falls. Hollis French and Allen Hubbard, consulting engineers, of Boston, are the engineers for the Manchester company on all of the work above described, being represented at the work by Mr. George G. Shedd, resident engineer. The general contractors for the work are Holbrook, Cabot and Rollins, and their superintendent at Garvin's Falls is Mr. J. B. Haviland. The other contractors on the plant are, for steel work, the Boston Bridge Works; for the station building, Waymire & Penniman; for the electrical machinery, the General Electric Company; for the switchboard, S. B. Condit, Jr. & Co.; for the water wheels, the Rodney Hunt Machine Company.

Especial thanks are due to Mr. J. Brodie Smith, general manager of the Manchester Traction, Light & Power Company, and to the engineers, Hollis French and Allen Hubbard, for aid in the collection of the above facts.

Rise of Electric Lighting in New England.

By Alton D. Adams.

BEGINNING OF ELECTRICAL SUPPLY.

CHARLES FRANCIS BRUSH exhibited a four-lamp arc dynamo at the Mechanics' Fair in Boston during October, 1878. On November 9, after the Fair, this dynamo and lamps began to operate in a building occupied by the Continental Clothing House, at the corner of Howard and Washington Streets. This was the first electric light plant installed for regular service in Boston, and probably in New England.

Much light is thrown on the state of the art at that time by the construction of this dynamo and lamps, which Mr. Brush thought of sufficient importance to warrant their exhibition by him in person. The armature core was a cast-iron ring with wide slots to receive the coils in radial directions on its two sides. There were eight of these slots on each side of the ring, and it was wound eight coils or bobbins as they were called. Diametrically opposite coils were connected in series, and the four pairs of coils thus formed had the two free ends of each brought out to a two-part commutator ring. Each of the four commutator rings was electrically independent of the others, and from each ring two bare No. 6 wires were carried to a single arc lamp. Independent commutators were necessary on this dynamo because the arc lamps had no automatic cut-outs, and when the carbons in any lamp had burned out its circuit was completed through only the fine shunt winding. Bare square carbon rods were used in these lamps, and their cost was 25 cents each.

The electric arc thus brought to public attention in Boston was soon seen at other points in New England. Isolated plants naturally come first, and then central stations for general lighting. One of the earliest, if ot the first public lighting system in New England, was that using the United States series dynamo and arc lamps in New Haven, Conn., which began to operate on July 4, 1881. The next year was one of much activity in the promotion of lighting from central stations, and equipments were installed for this service at Portland, Me.: Manchester, N. H., and Lowell, Lawrence, Lynn, Salem, Taunton and Springfield, Mass., in 1882. At Manchesser the first plant comprised 10 Weston arc dynamos with a capacity of ten lamps each, and was operated with rented power in one of the mills of the Amoskeag Maufacturing Company.

The Portland Electric Light Company had one small arc dynamo driven by a simple engine, and began to supply light in that city during February, 1882. In Lowell the first public lighting system was preceded by a plant of a Brush dynamo and ten arc lamps in the clothing store of Putnam & Son, on Central Street, which was started in operation about May 1, 1882. Later in the same year a company was formed for general lighting service, and three Weston arc dynamos with a capacity of ten lamps each were installed in the basement of Davis & Sargent's mill for this purpose. Circuits from these dynamos were run along Middlesex and Central Streets, where 30 arc lamps were hung, and the plant went into operation on the day before Christmas, in the year just named. The Middlesex Electric Light Company was formed and installed a public system of arc lighting with Thomson-Houston dynamos and lamps at Lowell in 1883, and this company was soon consolidated with the one that had preceded it. Sometime after this consolidation the capacity of the lighting system was increased by the addition of a 600-lamp, 110-volt Thomson-Houston dynamo for incandescent service.

Lawrence was the site of the first Edison three-wire system in the State, and probably in New England, the company for the installation of the Edison system there having been formed in 1882. In the same year the Lawrence Electric Light Company was formed for the operation of the Thomson-Houston system of arc lighting there, and both of the companies began their service before the end of the year. Some years later both of the electric companies sold their systems to the Lawrence Gas Company.

The Salem Electric Lighting Company began operations, in 1882, with the Thomson-Houston arc light apparatus. In the same year the Lynn Electric Lighting Company began service in that city from a Thomson-Houston dynamo that was driven by rented power in a shoe factory on Market Street, nearly opposite the station of the Boston, Revere Beach & Lynn Railway. A little later the plant of the Lynn company was moved to Stewart Street and provided with its own steam plant. In 1888 the gas and electric company at Lynn were consolidated under an act of Legislature. Electric lighting was begun at Springfield, in 1882, by the Blair Manufacturing Company with Thomson-Houston arc dynamos and lamps. The plant thus started was subsequently secured and operated by the Springfield Electric Light Company, and, in 1887, the entire system passed into the hands of the United Electric Light Company.

Every one of the first electric lighting systems just mentioned, with the single exception of the Edison at Lawrence, had been equipped at the start with only arc dynamos and lamps. In the following years incandescent lighting claimed a large share of attention. The Pearl Street Edison station in New York had been started in September, 1882, and was a striking example of what could be done in the multiple operation of incandescent lamps.

In May, 1883, the original Fall River Electric Light Company started its plant of one Thomson-Houston arc dynamo with power rented in a machine shop in that city. October of the same year saw an Edison station equipped in Fall River with its three-wire circuits entirely in underground tubes. In 1896 these two companies were consolidated under the name of th- former. An Edison company was also incorporated for operation in Brockton during 1883, and subsequently absorbed an arc lighting system operated there by another company.

This year of 1883 marks the beginning of electric lighting from central stations in Boston, and two companies then started their plants. One of these plants operated with the Brush arc dynamos and lamps, and its first machines were located in Ham's Iron Works on Portland Street. From this plant the first arc street lamps in Boston were operated. After a few months the dynamos of the Brush system were moved to a station on Lancaster Street, and still later to the well-known Ferdinand Street station. In the same year that the Brush company began operations, the Merchants' Light, Heat & Power Company rented a space in the basement of the Mechanics' Building on Huntington Avenue, and installed a 10-lamp Thomson-Houston arc dynamo driven by a small high-speed engine for general commercial lighting. This plant was soon made larger, and in 1885 was moved to 197 Congress Street.

The Massachusetts Electric Power Company was formed in the year last named, and installed at the Congress Street station of the Merchants' Company the first dynamo ever used in Boston for the distribution of current exclusively to electric motors. This dynamo was of the Daft make and rated at 50 hp and about 110 volts. Steam power was rented from the engine of the Merchants' Company to operate this Daft dynamo, and it is related that the engineer of this company would watch for the greatest loads on the Daft machine and then take cards from his engine to determine the basis on which the power used was to be computed. The power company operated only motors with their Daft dynamo, as it was thought impracticable at that time to supply both incandescent lamps and motors from the same machine. In this 50-hp, 110-volt Daft dynamo of 1885, with its two-wire circuits to nearby motors, might have been read the prophecy of the great electric motor load in Boston at the present day, but those most interested saw it not.

In 1884 another company, the New England Weston, entered the arc lighting field at Boston with dynamos and lamps of the Weston make. These three arc lighting companies, the Brush, the Merchants' and the Weston, operated in competition until about 1887, and were then consolidated in the Boston Electric Light Company, which was formed for the purpose. In this consolidation there was also included the power company that had started with the Daft dynamo.

During these hard, early years of competition capital did not flow to electrical enterprises as readily as it does now, and some amusing incidents are related of the financial straits to which the companies were sometimes put. Its contract for street lighting gave the Brush Company a degree of opulence not enjoyed by the others, which had to rely solely on their commercial business, and this led to a prodigal rejection of rather long carbon stubs by the trimmers of the street lamps. Knowing of this habit and also of the limited resources of their own employer, the trimmers of the Merchants' Company were wont to go about under the Brush street lamps and gather the rejected carbon stubs for their own use. It is even said that there were times when the operators at the Merchants' station were obliged to go out and buy oil with their own money to prevent shutting down the machinery. This company had a contract with the Hotel Brunswick to supply an arc lamp outside during the evening and also a contract with the Adams House to operate an arc lamp inside during a part of each day. Having only one arc lamp that could be devoted to both of these hotels, the employees of the Merchants' Company were obliged to carry this lamp back and forth every day. Sometimes when a day was darker than usual it required no small degree of strategy to get this lamp to the Brunswick early enough and yet not take it away from the Adams House too soon.

On December 31, 1888, the station bounded by Summer Street, Gilman Place and the water front, which had been built by the Boston Electric Light Company to care for the consolidated business of the earlier companies was started. The station of the Weston Company, on Stanhope Street, was continued in operation as part of the Boston system until 1893, and was then abandoned. The Ferdinand Street station was also continued in operation, and though burned down in 1893 was at once rebuilt. From 1898, when the L Street station was started, to 1902, when the Boston Electric system passed into the hands of the Boston Edison Company, the Ferdinand Street station did duty in the distribution of current from L Street, and was abandoned in the latter year. In 1894 the Boston Electric Light Company equipped its station on Boston Street with apparatus that had been exhibited at the World's Fair in the previous year. After 1898 the energy for the Boston Electric Light system was mainly generated at its last, best and largest station on L Street.

Combination of Independent Telephone Interests.

A number of representatives of independent telephone companies throughout the country arrived in St. Louis May 13 and held two business meetings. It is reported that it is the preliminary to a combination of interests in the near future. There was an executive session in the offices of the Kinloch Telephone Company, and another meeting was held in the afternoon. The entire party went to the World's Fair in the evening and was entertained at the "Tyrolean Alps."

Among the visiting representatives was a delegation from Pittsburg, Pa., whose members are believed to be leading the others in an effort to perfect a combine of the independent companies. The Pittsburg delegation has already visited Cleveland, Ohio; Toledo, Ohio; Grand Rapids, Mich.; Chicago, Ill., and Kansas City, Mo. Before returning to Pittsburg its members will visit Louisville, Ky.; Indianapolis, Ind., Dayton and Columbus, Ohio.

The following attended the executive session: James B. Hoge, of Cleveland, Ohio; J. A. Armstrong, A. L. Tetu and Col. J. D. Powers, of Louisville, Ky.; B. B. Sale, Indianapolis, Ind.; James S. Brailey, Jr., of Toledo, Ohio, director of the Home Telephone Company, of Kansas City, Mo.; J. G. Splane, president, and R. C. Hall, D. P. Reighard, William Flinn, John S. Weller, J. T. Braden, D. R. Williams, J. V. Wibbs, T. T. Misslin, John A. Howard, H. M. Nichols, H. B. Beatty, directors, and S. H. Browne, manager, Pittsburg and Allegheny Telephone Company; A. O. Stromberg, Chicago; C. Marquard Forster, president, W. Roy McCanne, secretary, and W. Linton Reber, general manager, Kinloch Telephone Company, St. Louis, and the following directors: Rolla Wells, Breckenridge Jones, William S. Nolker, E. H. Benoist, W. L. Benoist, Philip Scanlan and M. H. Clapp.

The Nature of Patents and Inventions.

Mr. Samuel G. McMeen delivered recently an address to the engineering student body of Lewis Institute, Chicago, on the above subject. He said that a patent issued by our government is a memorandum of a bargain between the inventor as one individual and the people of the country as another. This bargain is to the effect that because the inventor furnishes to the people a more or less useful product of his brain they in their turn guarantee to pay him for his effort. The payment is not made in a definite sum of money, but in an arrangement whereby he may enjoy for seventeen years all the profits coming from the use of the thing he has produced. Rights to these profits he may sell or rent to others or make such disposition as he likes, but from the time of the making of the bargain the thing belongs to the people. At the end of the seventeen years the inventor has no further claim on his production and it belongs thereafter wholly to the people, having been bought and paid for.

In a sense the price paid by the people is set by the inventor. It may be very large or very small, depending on the excellence of the invention or on the caprice of the people. Examples will come to mind of inventions almost trivial, so far as real usefulness is concerned, but which gave the inventor large financial return. There are other examples of inventions which were epoch-making, but because they were too soon for the minds of the pople, brought no financial return. It may be that if they had been invented later, so that the period of monopoly had coincided with the period of welcome, the reward might have been proportionate to the excellence of the conception.

The industrial greatness of this nation is in large measure due to the existence of good patent law and to the encouragement which has been given to inventors by its operation. The inventive ability of a people lies not alone in its facility in finding ingenious ways of setting things together to achieve results, but also in its wisdom to see clearly industrial and social needs. In the instance of the inventor who produced the cranberry sorter, everyone in the cranberry industry knew the need of sorting so that cranberries for market would contain no soft ones; it required a mental aptitude to see an immediate possibility of invention in the circumstance that when cranberries were spilled down the back steps only the sound ones hopped from step to step, the soft ones stopping early.

It is not true that a patent granted by the United States may be renewed. A reissue is not an arrangement by which an expiring patent may be given new life, but only an arrangement whereby a necessary correction may be accomplished. In other countries there are periods of patent life, which, by proper action, may be extended somewhat as in the case of a copyright in this country, but in each case there is an ultimate time beyond which the term of the patent cannot be extended.

An applicant may not secure a patent in this country if his invention has been in actual public use for two years or more before he makes his application. Interesting questions sometimes arise as to whether the use has been really public or might not have been wholly for the purpose of testing the efficiency of the invention by a continued test: A form of sidewalk which had been in use for two years was held not to vitiate the rights of the applicant because, although distinctly in public use, the excellence of its form could only be proven to the inventor by actual trial and could not be considered to be a final test unless continued for a considerable time. In another instance of an article of wearing apparel distinctly not public in its use, a period of two years was held wholly to vitiate the rights of the applicant because very much less than two years should have sufficed to enable him to decide whether the invention was or was not in a proper form for filing his application.

An Expression for the Torque of a Polyphase Wattmeter.

By F. R. Stowe.

Although the following discussion could apply to any polyphase recording wattmeter, the writer has in mind a standard type of a well-known make.

All recording meters for alternating-current circuits are really induction motors of very small power. The rotor of this meter is an aluminum disc. The stator comprises two sets of windings, each set consisting of two series coils and one potential coil. The potential coils have laminated iron cores, and in series with each, but placed so as not to act on the rotor, is another coil wound to have a high reactance. Each potential coil has a short-circuited secondary for

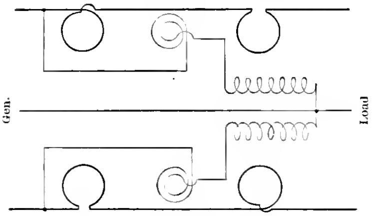

FIG. 1.—METER CONNECTIONS.

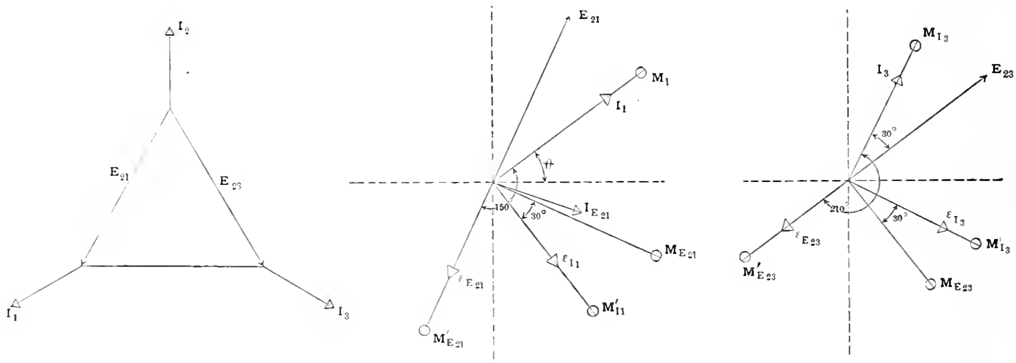
the purpose of bringing the lag of the magnetic flux behind the impressed e.m.f. to exactly 90°. By proper adjustment of the resistance through which it is "short-circuited" this can be done.

Fig. 1 shows how the meter is connected to measure the power in a three-phase circuit. It also indicates the direction of winding and the relative position of the coils. Let us take up first the case of a three-phase circuit with unity power factor of which Fig. 2 is the vector diagram. Let I_1 and I_3 be the currents flowing through the series windings and E_{21}, E_{23} be the corresponding e.m.f's. Consider I_1 and E_{21} as in, say, the lower set of coils in Fig. 1. There being no iron in the magnetic circuit of the series coils, the flux, M_I (see Fig. 3), is in phase with I_1, and the eddy currents, E_{I_1}, induced in the disc are 90° behind I_1. M'_I is the flux due to E_{I_1}.

In the potential circuit, however, the current, $I_{E_{21}}$, due to the high reactance, lags about 80° behind E_{21} and the effect of hysteresis and



FIGS. 2, 3 AND 4.—CURRENT DIAGRAMS.

the lag coil is to make the flux, $M_{E_{21}}$ 90° behind E_{21}. We thus have the following reactions to consider: Between M_{I_1} and $M'_{E_{21}}$, 150° behind M_{I_1}; and between $M_{E_{21}}$, 60° behind M_{I_1}, and M'_{I_1} 30° behind $M_{E_{21}}$.

The torque produced by the reaction between M_{I_1} and $M'_{E_{21}}$ is positive when their instantaneous values have opposite signs, and negative when these values have the same sign. Thus, it is not uniform throughout a cycle, but varies from a large positive value to a comparatively small negative value. The same is true of the torque produced by $M_{E_{21}}$ and M'_{I_1}. The sum of these two torques, however, is positive and constant, as may be shown as follows:

The torque due to M_{I_1} and $M'_{E_{21}}$ at any instant is

$$T' = -C M_{I_1} \sin\theta\, M'_{E_{21}} \sin(\theta - 150);$$

that is, the product of their instantaneous values. The minus sign is used because when these values have opposite signs T' is positive. C is a constant depending on the units in which T'_1, M_{I_1} and $M'_{E_{21}}$ are expressed and on the distance between the coils. Or we may write it:

$$T' = C M_{I_1} M'_{E_{21}} \sin\theta \sin(\theta + 30).$$

In the same way we get the torque due to $M_{E_{21}}$ and M'_{I_1}:

$$T'' = -C M_{E_{21}} M_{I_1} \cos\theta \sin(\theta - 60).$$

Then the total torque is:

$$T_1 = T' + T'' = C\,\{ M_{I_1} M'_{E_{21}} \sin\theta \sin(\theta + 30) - M_{E_{21}} M'_{I_1} \cos\theta \sin(\theta - 60) \}.$$

Let $A = \frac{M'_{I_1}}{M_{I_1}} = \frac{M'_{E_{21}}}{M_{E_{21}}}$, as it depends only upon the frequency and the resistance of the disc. Substituting in the above equation for T_1 values of M'_{I_1} and $M'_{E_{21}}$ in terms of M_{I_1} and $M_{E_{21}}$ and simplifying the sine and cosine terms we get

$$T_1 = C A M_{I_1} M_{E_{21}} \cos 30 = \text{constant}.$$

The above result could have been arrived at in a simpler manner, which follows, but it would not have been so clear that the torque is constant throughout a cycle.

The reaction between two fluxes is proportional to the vector product of their effective values, so we have

$$T' = C \frac{1}{\sqrt{2}} M_{I_1} \frac{1}{\sqrt{2}} M'_{E_{21}} \cos 30°$$

$$T'' = C \frac{1}{\sqrt{2}} M_{E_{21}} \frac{1}{\sqrt{2}} M'_{I_1} \cos 30°,$$

substituting as before $A M_{I_1}$ for M'_{I_1}, and $A M_{E_{21}}$ for $M'_{E_{21}}$, we get

$$T' = \frac{CA}{2} M_{I_1} M_{E_{21}} \cos 30° = T''$$

and $T_1 = C A M_{I_1} M_{E_{21}} \cos 30°$.

In the same manner we get the torque produced by the other set of coils (see Fig. 4):

$$T_3 = C' A' M_{I_3} M_{E_{23}} \cos 30°.$$

If we assume now the current to lag $\phi°$, the above expressions would be changed in one respect only, $\cos 30°$ becoming $\cos(30 + \phi)$ and $\cos(30 - \phi)$, and we would get as an expression for the total torque,

$$T = C A M_{I_1} M_{E_{21}} \cos(30 + \phi) + C' A' M_{I_3} M_{E_{23}} \cos(30 - \phi),$$

which corresponds exactly to the expression for the power:

$$P = I_1 E_{21} \cos(30 + \phi) + I_3 E_{23} \cos(30 - \phi),$$

showing that T varies as P.

We have neglected in the above discussion the effect of magnetic leakage, and the rotation of the disc, upon T. Tests made on one meter showed a difference of about 2 per cent. between the starting and the running torques.

Alternating-Current Wave Form Analysis.

BY S. M. KINTNER.

WHILE it is quite generally known that the wave forms of current and voltage of alternating-current machinery can be represented by a series of sine waves varying in frequency, phase and amplitude, it is not so commonly known *how* any given complex wave form can be split up into such a series. It is the purpose of this article to supply such information, in the form of tables of constants which can be used in such analysis, and to discuss briefly the theory of the method, giving such instructions as are needed to carry out the analysis of the ordinary forms of waves encountered in practice. The greater part of the matter presented is not new, but the fact that methods of wave form analysis are not as generally known by active engineers as its importance warrants, may serve as a sufficient reason for presenting the following:

FUNDAMENTAL PRINCIPLES.

Fournier has shown, in a mathematical theorem bearing his name, that wave forms which are single-valued periodic functions, such as those of alternating currents, can be represented by a series, the first term of which is a constant and each of the terms following are sines and cosines of an angle multiplied by a constant. Expressed analytically any wave form can be said to be equal to:

$$A + A_1 \sin \omega t + B_1 \cos \omega t + A_2 \sin 2\omega t + B_2 \cos 2\omega t + A_3 \sin 3\omega t + B_3 \cos 3\omega t + \ldots \ldots + A_n \sin n\omega t + B_n \cos n\omega t. \quad (1)$$

Where the A and B factors are the amplitudes of the various sine and cosine component waves; ω equals a constant angular velocity, and so ωt represents an angle varying with time.

By the proper choice of the X axis along which t is measured, the first constant, A, will reduce to zero while no change will take place in the other factors. The condition for this is that the two halves of the wave, above and below the axis, shall have equal areas. As the alternating-current waves encountered in practice are plotted thus, the discussion following will be based on that assumption.

It will be seen on inspection of equation (1) above that its factors occur in pairs, sines and cosines of the same angles. By a simple trigonometric transformation, these factors in pairs, i. e. $A \sin \omega t + B \cos \omega t$, can be expressed as a single function of the same angle and made to appear as $C \sin (\omega t + \theta)$.

The method of making this transformation and determining the constants, C and θ, is as follows: Looking at Fig. 1, where the three factors are represented on the left-hand side of the figure by the three lines diverging from a common center, o, the relation between them will be seen at once.

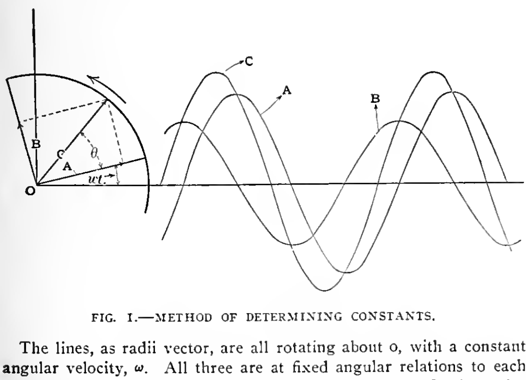


FIG. 1.—METHOD OF DETERMINING CONSTANTS.

The lines, as radii vector, are all rotating about o, with a constant angular velocity, ω. All three are at fixed angular relations to each other, and C is seen to be the resultant of A and B, at a fixed angular position to A, determined by the relative values of A and B. The angle, θ, is seen to be one having a tangent equal to B/A. It is perfectly evident that the numerical values of C is $\sqrt{A^2 + B^2}$.

The right-hand side of Fig. 1 shows the three sine curves that the radii vector, A, B and C, would develop if the sines of the angles are plotted as ordinates and the angles as abscissæ, the angles being measured between the horizontal axis and the respective radii. It will be seen on inspection that the instantaneous value at any point on curve C is equal to the sum of the values of A and B taken at the same point, care being taken to allow for change of sign for all values below the axis; consequently, curve C is a correct representation of the resultant of the two curves, A and B.

The method of performing the transformation, then, for a given expression, $A \sin \omega t + B \cos \omega t$, is indicated thus:

$$\sqrt{A^2 + B^2} \sin (\omega t + \tan^{-1} B/A).$$

The various sine waves into which a complex wave can be subdivided are known as fundamental and harmonics, the fundamental having the same frequency as the complex wave from which it is derived. The harmonics may have any multiple frequency, though in general only the odd frequencies will occur, as will be explained later. Thus a sine wave of a given frequency, such as three times that of the fundamental, representing the sum of a sine and a cosine wave of the same frequency, is known as the third harmonic. The sine and cosine factors from which a particular harmonic is determined are known as the sine and cosine components of that harmonic.

The components of the various harmonics being more readily determined than the harmonics proper, and their phase relations, that method is the one generally used. After the components are determined it is a simple matter to perform the transformation indicated above, and thus get the harmonic and its angle of lead or lag.

The fact that

$$\left.\begin{array}{l} \int_0^\pi \sin x \sin nx\, dx \\ \int_0^\pi \sin x \cos nx\, dx \\ \int_0^\pi \cos x \cos nx\, dx \\ \int_0^\pi \sin x \cos x\, dx \end{array}\right\} = 0.$$

(Where n is any integer other than unity)

is the fundamental principle upon which is based practically all of the methods of harmonic analysis.

With the above in mind, it becomes evident that if any complex wave, expressed as a series of sine and cosine component harmonics, is multiplied by a test wave, such as $\sin nx$, and all these products integrated between the limits indicated above, the result will be zero for each and every term excepting the sine component of the harmonic of frequency n. If the result of the entire operation is zero, it is proof that there is no sine component of that particular harmonic present. It is evident, then, that the components of the various harmonics are picked out, one at a time, by the use of test waves. Thus, to determine if the sine component of the nth harmonic is present, the complex wave series is multiplied by a sine wave of unit amplitude and a frequency n times that of the fundamental, and all products reduce to zero on integration, save the sine component of the nth harmonic, if such is present. Such an operation expressed analytically would, after integration, stand thus:

$$0 + 0 + 0 + 0 + \int_0^\pi \sin nx\, A_n \sin nx\, dx + 0 = \frac{A_n \pi}{2}$$

The indicated integral is the equivalent of the area of a curve formed by the products of all ordinates of the two sine waves of the same frequency, but different amplitudes. This area is seen to equal $\frac{A_n \pi}{2}$, and A_n is the value that is desired. Thus A_n is equal to $\frac{2}{\pi}$ multiplied into the result of the entire operation of multiplication and integration.

What has been said regarding the determination of the sine components is equally true regarding the cosine components, and they are determined in a similar manner, using cosine testing waves in the latter case, of course.

While the above indicates the correctness of principles, it is not enough to enable one to actually analyze a wave such as is determined experimentally, as it would be simply a curve on paper without any analytical series expressed. What is wanted, then, is some way of summing the products of every ordinate of the complex wave into those of the various test waves. For an analytical method, where no recourse is had to any mechanical integrating device which would also allow for the products with the test wave, the best that can be done is to select a definite number of evenly-spaced ordinates of the complex wave form, measure them, multiply them by ordinates in the corresponding angular relations of the test waves, and sum the products. Such a method would be an approximate integration of the products of the test wave and the series, and the result of such an operation must relate only to the sine or cosine component of the harmonic of the same frequency as that of the test wave, according as the test wave is a sine or a cosine function.

The amplitude of the component harmonic is determined from the residue of the last operation by multiplying it by 2 divided by the base of the complex wave, which in numerical value will equal the number of equal parts into which the base is divided.

Todhunter has proven the truth of the above statements in his integral calculus, and expresses the value of the amplitude of the sine, or cosine components of any harmonic, m-, in the following manner:

$$A_m = \frac{2}{n+1}\left[e_1 \sin\left(m\frac{180}{n+1}\right) + e_2 \sin\left(2m\frac{180}{n+1}\right) + e_3 \sin\left(3m\frac{180}{n+1}\right) + \;.\;.\;.\;.\;.\;.\; + e_n \sin\left(nm\frac{180}{n+1}\right)\right]$$

$$B_m = \frac{2}{n+1}\left[e_1 \cos\left(m\frac{180}{n+1}\right) + e_2 \cos\left(2m\frac{180}{n+1}\right) + e_3 \cos\left(3m\frac{180}{n+1}\right) + \;.\;.\;.\;.\;.\;.\; + e_n \cos\left(nm\frac{180}{n+1}\right)\right]$$

Where the symbols have the following meanings:

A_m = amplitude of the sine component of the mth harmonic.
B_m = amplitude of the cosine component of the mth harmonic.
n = number of measured ordinates.
e_1, e_2, e_3, e_n = values of the measured ordinates taken in the regular order of sequence in which they were measured.

Using these formulæ, it is seen how, by dividing the base of one alternation of the complex wave to be analyzed into $n + 1$ equal parts and measuring the n ordinates at the points of division, it is possible to determine the sine, or cosine component of any harmonic desired.

In performing such an operation there is considerable labor involved in determining the various trigonometric values indicated.

As these values are in no way dependent upon the wave under investigation, but depend only on the number of equal divisions into which the base is divided, it is evident that a table of constants can be determined for use with a particular number of base line divisions. Such a table has been devised and is submitted in the following form as one that is convenient to use. It is based on the assumption of a base line division of thirty-six equal parts—an ordinate every five degrees of the fundamental—and can be used for that, or for an eighteen-part base line division, where so great accuracy is not required. To obviate the labor and liability of error in transcribing these constants every time it is desired to use them, it is suggested that copies of the tables be made on some duplicating machine such as a mimeograph, leaving blank columns for calculations as in the arrangement of the tables I to V.

It will be noticed that the constants are calculated for the odd harmonics only. This is for the reason that all wave forms that are symmetrical about the X axis contain only the odd harmonics; the even harmonics always produce a lack of symmetry between the alternations above and below it. As most of the wave forms encountered in practice are of that type, it was not considered advisable to in-

clude the even harmonics in the table above. Any one desiring to determine the value of the even harmonics, in a case where such is necessary, can do so by calculating the values required from the Todhunter formulæ given above.

Another characteristic of wave forms is worthy of note in passing. That is, all wave forms symmetrical about both the X axis and the middle ordinates of each alternation have zero as the value of the cosine component of all harmonics. The truth of this is readily seen from the relations of the constants under the various B's; they are all symmetrical, but of opposite sign, about their middle value. The cosine components all reducing to zero, shows that all harmonics pass through one of their zero values at the same time that the fundamental does.

It is seldom one has an opportunity of utilizing this last characteristic in investigating wave forms determined experimentally, but it can be used in studying assumed wave forms of that type.

INSTRUCTIONS FOR USING THE TABLES OF CONSTANTS.

It is intended that the following instructions shall be complete enough, so that any one can perform the operations of the analysis without having read over all the preceding discussion of the principles.

First, take the wave to be analyzed and divide the base line into thirty-six equal parts, starting at the zero value of the wave. Erect ordinates at each point of division and measure their values. Place the values of these measured ordinates in the left-hand column of the table, marked "Measured Ordinates." Next, multiply each measured ordinate by the constants in the various columns opposite; this is quite readily done by means of a slide rule. The two blank columns are left to the right of each column of constants in order that the positive and negative products can be placed in separate columns and thus render the addition of the columns more certain. All the columns of products should be added and the difference between the positive and negative values determined for each set of pairs of columns. This difference for each is then multiplied by the constant .0555, care being taken to preserve the sign of each oper-

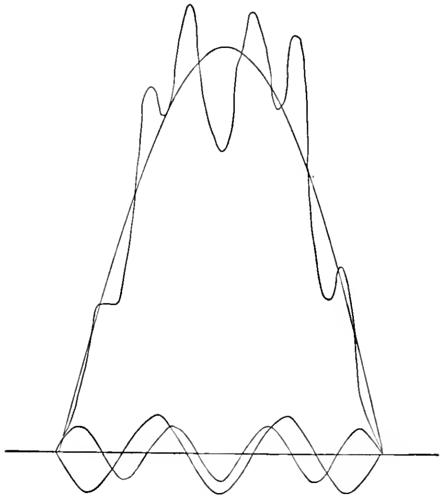

FIG. 2.—FIFTH HARMONIC OF THE CURVE.

ation. The products resulting from the constant .0555 into the various differences are values of the amplitudes of the respective component harmonics, the number of the harmonic being indicated by the subscript of the letter A, heading the columns of the constants in the table, for the sine components and the letter B, for the cosine components.

Having determined the components of the various harmonics, as described above, the harmonic is determined thus: Its amplitude is $\sqrt{A^2 + B^2}$, and the harmonic goes through its nearest zero value to the zero value of the fundamental, at an angle whose tangent is B/A, ahead, or behind the fundamental as determined by the signs of A and B. The rule for determining angles between the fundamental zero and the nearest harmonic zero to it, is as follows: If A and B are both positive, the harmonic is ahead of the fundamental less than 90°, by an angle whose tangent is B/A; if A is negative and B positive, the harmonic is ahead, an angle less than 180°, but greater than 90°, whose tangent is B/A; if A is negative and B negative the harmonic is lagging at its zero nearest the fundamental zero by an angle less than 180° and greater than 90°, whose tangent is B/A; if A is positive and B negative, the angle of lag is less than 90° and is the angle having a tangent equal to B/A.

As an illustration of the above instructions, the fifth harmonic of the curve, of which one alternation is shown in Fig. 2, will be determined.

The thirty-five measured ordinates are placed in the left-hand column of the table of constants for the two component curves of the fifth harmonic, the multiplications and summations made, as will be seen in the following tabular form:

$A_5 = .0555 \times - 14.737 = - .817,$
$B_5 = .0555 \times - 1.531 = - .084.$

The two components of the fifth harmonic can now be written as

$$- .817 \; sin \; 5 \omega t - .084 \; cos \; 5 \omega t.$$

Resolving the two component waves into the resultant harmonic, thus:

$$\sqrt{(- .817)^2 + (- .084)^2} = .822,$$

the value of the amplitude; the angular relation is gotten as the angle whose tangent is $\dfrac{- .084}{- .817} = 5^\circ \; 52'$. The rule given above, for determining the sign of the angles as well as their size, states that when both components are negative, the angle is a lagging one, greater than 90° and less than 180°: this case reduces to an angle then of 174° 8′. The harmonic as finally determined is written thus:

$$.822 \; sin \; (5 \omega t - 174^\circ \; 8').$$

1.775	.966	1.715		—.259		4.60
.98	.766	.75		—.643		.63
.507	.423	.214		—.906		.459
		58.822	73.549		67.856	69.387
			58.822			67.856
			—14.737			—1.531

A complete analysis, up to the 17th harmonic, of the wave above, Fig. 2, gives the following:

$$9.02 \; sin \; (\omega t + 0^\circ \; 23') + .0825 \; sin \; (3 \omega t + 57^\circ \; 26')$$
$$+ .822 \; sin \; (5 \omega t - 174^\circ \; 8') + .607 \; sin \; (7 \omega t + 10^\circ \; 40')$$
$$+ .433 \; sin \; (9 \omega t + 158^\circ \; 36') + .482 \; sin \; (11 \omega t + 93^\circ \; 3')$$
$$+ .029 \; sin \; (13 \omega t - 37^\circ \; 12') + .196 \; sin \; (15 \omega t + 137^\circ \; 33')$$
$$+ .435 \; sin \; (17 \omega t + 51^\circ \; 20').$$

The fifth, seventh and thirteenth harmonics are particularly prominent and have amplitudes of about ten per cent. of that of the fundamental. The fundamental, fifth and seventh harmonics are drawn in Fig. 2.

Radium and Terrestrial Heat

Prof. Rutherford, of McGill University, Montreal, in a lecture before the Royal Institution in London, has advanced the striking theory that the earth's heat is not attributable to a molten mass which has been slowly cooling for a million years, which has been the generally accepted theory, but to the presence of radium. Prof. Rutherford's address was listened to by a distinguished audience, including Lord Kelvin, Lord Rayleigh, Prof. Dewar and other great scientists. Prof. Rutherford was the first to measure the mass and velocity of the electrons of radium. He announced the probability of radium being contained in all matter.

Glimpses of Steinmetz.

In the June *World's Work* Arthur Goodrich tells some interesting stories about Mr. Charles P. Steinmetz, chief engineer of the General Electric Company at Schenectady. "One of his ablest assistants spent a number of days of hard work in solving an intricate mathematical problem. When he had finished it he asked Steinmetz to work it out. The inventor grasped the problem at once, counted on his fingers a few times, and gave the correct answer without touching pencil or paper. Yet he remarked recently: 'Mathematics is valuable only to obtain results. Mathematics for mathematics' sake is foolishness.'

"Some years ago Steinmetz went into the Adirondacks with a hunting party of friends. Not caring to hunt, he was often left alone at a little lodge that was made the party's headquarters. One night before the camp fire a mathematical question came into his head. To settle it he needed a table of logarithms which could not have been found within miles of the camp. He remembered a few figures, and in a short time had worked out an entire table of logarithms for himself, and from it solved the problem. This mathematical sense, which was originally trained by hard study at Breslau, makes it possible for him to answer quickly the rapid fire of questions his aids hurl at him daily.

"The laboratory workers come to him constantly for advice and direction. Eighteen thousand employees stand ready to work out his ideas. With the men he is always genial and democratic. When any business matter needs settling he does it in determined fashion. He is as independent as he is good-natured. When the heads of the works made a rule against smoking in the factory, Mr. Steinmetz said he would smoke or leave. He did not leave. 'He can accomplish more in an hour,' said one of his assistants, 'than I can do in a week.' If some difficult problem needs solution at the works, it is nearly always taken to Steinmetz.

"Not long ago there was an explosion in a manhole in New York City, which made great trouble for an electric railroad. Many local engineers tried to find the cause of the trouble, and gave various unsatisfactory explanations. The matter was brought to Mr. Steinmetz's attention. In a few moments he asked how certain adjacent wires in the manhole were covered. Here, indeed, was the trouble. It was simple, but no one else had thought of it. He takes the short cut to the essential thing. It is characteristic of all his work."

Recent Electrochemical Developments.

Two patents granted on May 17 to Mr. Alfred H. Cowles, of Cleveland, refer to methods of manufacturing calcium carbide. There is nothing new of a fundamental nature in his method since the carbide is produced simply by heating a mixture of lime and carbon to a high temperature. The patents refer rather to details of the method. Mr. Cowles intends to make the operation continuous and superheats the carbide so that it may be easily tapped off.

A patent granted to Mr. R. N. Pelton, of Detroit, Mich., refers to an electric furnace for dentists. Its essential part is a muffle with a heating coil of platinum wire in the wall. The outside of the muffle is surrounded by another heating coil.

Mr. P. J. Boucher, of Cleveland, Ohio, patents an apparatus for purifying water by electrolysis with the aid of aluminum electrodes. As well known, a flocculent hydrate is thereby produced which coagulates the various impurities and allows them to be easily removed from the liquid by settling or filtering. If the current always goes in the same direction, deposits form on the electrodes and interfere with their action and the electrodes unequally deteriorate. To counteract this tendency, the inventor automatically reverses the current at predetermined periods of time. He also provides means for automatically relieving the pressure of the gases evolved by electrolysis and for insuring the current being turned on or off whenever the liquid is turned on or off.

A patent granted to Mr. F. Hinz, of Berlin, Germany, refers to a process of manufacturing peroxides of magnesium and zinc in a diaphragm cell. For making magnesium peroxide he uses an aqueous solution of magnesium chloride in the anode compartment and a neutral solution of magnesium chloride and hydrogen peroxide in the cathode compartment. Magnesium deposited on the cathode by the action of the current reacts with the hydrogen peroxide and yields magnesium peroxide.

Discussion of Institute Papers.

The discussion of the papers read before the recent annual meeting of the American Institute of Electrical Engineers was quite extensive, particularly that of the first day. The paper by Mr. W. L. Waters on "Predetermination of Sparking in Direct-Current Machines," and that of Mr. E. H. Anderson on "Effect of Self-Induction on Railway Motor Commutation" were discussed together. Referring to the latter paper, Mr. Waters said that Mr. Gano S. Dunn some ten years ago proposed the method outlined for finding the self-induction of commutation. In reference to the statement that one cannot run with impunity 5, 6 or 7 coils per slot, he pointed out that this is due to the peculiar conditions of a railway motor. An oscillagram shows that the field of the armature is almost constant over quite a considerable distance; and though one may be commutating under different conditions for different coils, yet the field is almost constant. A series current motor with a brush on the neutral point is a special case, having little relation to the ordinary direct-current machine.

Mr. E. R. Douglas pointed out that there are two systems of flux giving rise to self-induction. A great part of the flux goes directly across the slots above the coil and through the wire itself, but a further and larger portion spreads out in all directions and flows parallel to the shaft as well as along the shaft. He gave an account of experiments made by the Crocker-Wheeler Company, in which a sphere of high permeability was used with a circular coil lying on the surface, and discussed at length the results of the experiments. He also discussed other experiments by the same company having a relation to the subject of Mr. Anderson's paper. His conclusions were that there are very many things to be taken into account in a formula for sparking. Mr. Thornburn Reid discussed in detail the paper by Mr. Waters with reference to work that he has been doing on the same problem, which work he states is nearly at a point where he is ready to bring it before the Institute. He has found that for one set of brushes the variation of the current from what might be called perfect resistance commutation depends not on inductance e.m.f. alone, but on the ratio of the reactance and the contact resistances or the brush surfaces. He things that if this factor were used in place of that for reactance voltage there would be an entirely different relation in the variation of the constant. A further factor that affects the question is that of the frequency of the commutation periods. Referring to the calculation of self-inductance of an armature coil, Mr. Reid said that in his method, which differed considerably from that of Mr. Waters, instead of taking the depth of the slot he took only the depth above the winding.

In the discussion of Mr. Winship's paper on "The Calculation of Railway Storage Batteries," Mr. F. J. White said that the method of determining the average running current per car by station wattmeter readings will not give the variation of the current throughout the line, and very often that variation will determine where the central point with respect to the battery is located. In regard to the matter of sub-station storage batteries, he has found that with the average schedule of load, say, half-hour or hourly cars, it has been found economical to install storage batteries. Mr. Lamar Lyndon said that the results of Mr. Winship corresponded in general with those developed by Sarrat, of Brussels, and that he obtained similar results in 1902. In these latter, however, and in the formula of Mr. Sarrat, the internal resistance of the battery was taken into consideration, which factor Dr. Winship has apparently neglected, but which must be reckoned with. The character of the generator from which the load is supplied must also be considered, since it affects some of the factors in the formula offered. He referred to a specific case where, without considering these factors, the booster worked out at 24 kw, whereas when the factors mentioned were taken into consideration, the size came out at 12 kw.

Mr. E. H. Anderson criticised the formula of Mr. Waters as not taking into consideration all of the important factors and went into considerable detail with relation to the principles of sparking. Mr. Winship in replying to Mr. Lyndon, said that in his experience it was not possible to obtain a value of the internal resistance of a battery that could be worked with. In using the calculations as they appear in his paper, he has been able to come out within a very few per cent. of observed results.

President Arnold said that in sub-station work he has in general made it a practice to connect each terminal cell to a line and connect to the bus-bar so as to go in and out of the cells to keep the feeders properly charged and keep track of the batteries. He usually installs 4, 5 or even 10 or more cells than needed in practical operation. Owing to the variable conditions, the best calculation seldom hits the proposition on the start. Mr. F. D. Newbury supplemented the paper by Mr. Lamme on "A 10,000-cycle Experimental Alternator," with notes on the measurement of voltage, iron loss tests, short-circuit tests and effects of high-frequency currents. Mr. J. H. Cuntz referred to a somewhat similar machine designed by Mr. Tesla in 1890 for high-frequency experiments at Columbia College, which was operated at from 10,000 to 12,000 cycles and was designed for 20,000 cycles. In general appearance the machine was similar to that described in the paper.

In the discussion of the paper by Mr. Barnes on fly-wheels, Prof. Franklin went at length into the question of parallel operation. He said that he had worked out a mathematical development, the denominator of which covered two pages and the numerator covered seven pages of paper. Prof. Clarence Feldmann, of Darmstadt, Germany, confirmed Mr. Barnes in a statement that in the case of gas engines driving alternators a lighter fly-wheel and heavy damping are needed. In the case of any prime-mover with small uniformity of speed a light fly-wheel and heavy damping are required. He referred to a formula by Boucherot for the fly-wheel, which he thought was the best that had been offered. He said that in designing he never used a damper, but used steel poles, which act partly as dampers. By the use of heavy fly-wheels and the natural damping produced either by steel poles or by coils short-circuited on top of each pole, trouble from hunting may be avoided. Prof. Feldmann referred to several specific cases of parallel operation in which the difficulties due to damping had been overcome by various arrangements. Prof. Franklin, after concluding the reading of the paper, on "The Induction Motor," supplemented it with some remarks in which he referred to the difference between the theory which he offered and that of Mr. Steinmetz on the same subject.

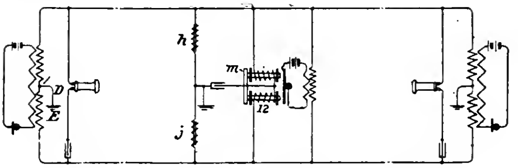
In a further discussion of the paper by Messrs. Waters and Anderson, Prof. Feldmann said that Mr. Waters greatly underestimates the influence of the shape of the pole pieces, and the reactance voltage is only the sole criterion as to sparking for one special type of machine. He believed that Mr. Anderson's statement that a motor of identically the same design will commutate better at 150 than 500 volts, is somewhat misleading or inexact. At the same current and speed and half the field the commutation will be worse. If, however, only half the current is taken at half the volts, the commutation will be better. He agreed with Mr. Reid that not only the self-induction, but also the mutual induction between the adjacent armature coils, should be taken into account in the sparking problem, and that other points should be considered, such as the frequency, and the contact resistance of the brushes. He stated that Prof. Arnold, of Carlsrhue, with the assistance of Prof. Mic, of Kiel, in 1898 completed and solved the differential equation applying in commutation, and in Prof. Arnold's book the formula is given with all the data necessary to figure self and mutual induction for any arrangement of coils in the slot.

Mr. H. Ward Leonard referred to a statement of Mr. Anderson in regard to sparking effects in starting the series motor for railway operation, and he considered that this was inherent in the type. For railway operations the best effects can be obtained by having the field of a motor separately and continually excited. He referred to experiments with an automobile where with series motors separately excited the automobile gave much better service than with self-excited fields. The automobile climbed with the same load and the same grade, with an expenditure of 120 watts in the field instead of 1,100. He referred to the experiments in Switzerland with the Ward Leonard system in connection with heavy railway work, in which difficulty with commutation at the generator was at first experienced, but which difficulty has been entirely overcome. He stated that a 20-km. trial of the railway system would shortly be made in Switzerland. The source of power is 15,000 volts alternating. The locomotive, which is capable of developing about 1,000 hp, has a single-phase motor which drives a direct-current generator, the armature of which is connected in multiple with the armatures of the motor. A separate machine excites the generator field and also excites the motor fields. In the generator field is a rheostat which enables the magnetism of the field to be reversed or given any degree of magnetism desirable, so that the entire control of the locomotive in starting, accelerating, retarding, stopping or reversing is all accomplished by the manipulation of one handle.

New Telephone Patents.

REPEATING SYSTEMS.

If one considers the metallic circuit telephone line in contrast to the grounded line, its predecessor, it seems very natural that early telephone managers were so loth to abandon the latter, for not only does the metallic circuit require double the length of wire, but incidentally the line resistance to be talked through at the same time is approximately doubled. If, however, by some means the two wires of our metallic circuits could be used in parallel, not only would the low-resistance conditions of grounded circuits obtain, but even this resistance would be halved. In a new repeating system just brought out, such a result is approached, in that for at least a considerable portion of the line the two conductors do work in parallel. The system referred to is that described in a patent recently issued to J. J. O'Connell, of Chicago, and assigned to the American Telegraph & Telephone Company. In the figure is shown a diagrammatic view of a completed through connection, at the middle being shown



O'CONNELL APPARATUS FOR AMPLIFYING AND REINFORCING TELEPHONE CURRENTS.

the repeating station and at the ends the two subscriber's stations. The operation may be best made clear by tracing the talking current from one station to the other. Consider the left-hand station. Current in the primary of two induction coils, varying in response to the transmitter, induces currents in the secondaries. These latter are so poled as to impress upon their junction point, *D*, which is grounded, equal currents of like sign, and similarly to send out upon the two sides of the metallic circuit two equal currents of like sign. These currents complete their circuit though the earth to which they pass at the repeating station through the coils of the repeater, *m*. Thus for transmitted or "sent-out" currents, as far as the repeating station the line wires serve in parallel. At the repeating station the incoming currents are cumulative in effect and actuate the diaphragm, thus sending out upon the line a repeated current.

As will be readily understood from the circuit diagram, this repeated current uses the advance line as a metallic circuit. At the receiving station practically all current passes through the telephone as the two induction coil secondaries, which in series form only shunt circuit about it, have in this relation such a high impedance as to be of no effect. Operation in the reversed direction is, of course, exactly similar. It may be well to state that the coils, *h*, *j*, at the repeating station serve to relieve the line of extraneous currents which might affect the repeater. To this end these coils are wound of low resistance, but of high inductance.

The ringing generator patent, issued to E. H. Strauss, describes a separately excited generator, the electromagnetic field being supplied from a battery. The automatic generator switch contains elements to control the field current so that the circuit will be closed only during the time of actual signalling.

CURRENT NEWS AND NOTES.

CONVENTION OF RAILWAY TELEGRAPH SUPERINTENDENTS.—The twenty-third annual meeting of the Association of Railway Telegraph Superintendents will be held at Hotel English, Indianapolis, Ind., June 15 and 16 next. Papers on topics relative to telegraphs and telephones will be read, and there is promise of a meeting of unusual interest. The members will probably proceed to St. Louis in a body to visit the Exposition. Mr. P. W. Drew, Milwaukee, Wis., is secretary of the Association.

INVESTIGATING RUBBER SUPPLY.—The United States Government is making investigations and has already issued a bulletin upon the subject of rubber gathering in the Philippines. It is known that in some of the southern islands the Hevea or Para rubber tree grows as perfectly as it does upon the Amazon and its tributaries, and in all of the islands the Castilloa or Mexican rubber tree can be made to grow. This is a matter of extreme importance to the Philippines and of the utmost interest to the American trade in general.

WHERE NEPTUNE DROWSES.—In the *Booklovers' Magazine* for June, Mr. P. T. McGrath has a very interesting article on life at St. Pierre Miquelon, the last Atlantic stepping stone for Europe. Water pipes running from reservoirs in the hills, and electric lights replacing the quaint oil lamps whose ornamental iron brackets still adorn the street corners, are the sole evidences of modern progress. There are no trams, street cars, telephones, newspapers, theatres, laundries or other accessories of advanced existence. Everything is sleepy, restful, and old-fashioned. Save for the Atlantic cable which touches there, it is as isolated from the world as Greenland.

DEPRECIATING THE STEAM ENGINE.—Writing under the title of "The Superseding of Steam Power," in the June *World's Work*, Lewis Nixon says: "I have been led, lately, to think the whole development of the steam engine, to the exclusion of the gas engine, has been a mistake, and that we are now at the beginning of a new era in the use of power. Engineers could to-day gain better and more economical results by abandoning steam and using internal combustion engines, even in large establishments. The gain in economy of fuel will advance with the size of the establishment. With the internal combustion engine, a brake horse-power can be produced on a pound of coal. This could not be done with steam under any conditions.

LETTERS TO THE EDITORS.

Reduction of Titanic Chloride.

To the Editors of Electrical World and Engineer:

SIRS:—We read on page 525, Vol. XLI of the ELECTRICAL WORLD AND ENGINEER (No. 13, of March 28, 1903), a note of Mr. Townsend, according to which a patent has been granted to Mr. Howard Spence, of Manchester, for the electric reduction of titanic chloride to titanous chloride. This conveys an impression that Mr. Spence had alone a right of carrying out this reduction.

We take the liberty of pointing out to you that the electric reduction of titanic chloride to titanous chloride has been put at everybody's free disposal through a publication of E. Polidori, which appeared in the beginning of the year 1899. (See *Zeitschrift für Anorganische Chemie*, Vol. XIX, page 306, and *Chemisches Zentralblatt*, 1899, Vol. I, page 518.)

NÜRNBERG, GERMANY. PAUL ASKENASY.

Italian Transmission Line Construction.

To the Editors of Electrical World and Engineer:

SIRS:—I have in hand the issue of your journal of March 12 and I tender my very best thanks for the lengthy editorial notice of my paper on "High-Tension Construction." I desire, however, to clear up some points which, it would appear, were not made thoroughly plain in the paper.

A system of land expropriation at so much per pole is extensively in use all over Europe. Of course, there are cases in which the full right of way is purchased, but even in these cases distinction is made between right of way and occupation of land; the first is paid at so much per meter of line, while the second is paid at so much per pole.

Referring to climatic difficulties, the writer of the editorial seems to consider the climate all over Italy as the climate of Naples and Rome, thus forgetting that most of the important lines run from the Alps, where snow, wind and variations of temperature are very severe. On the other hand, I do not very well understand how severe climatic conditions may be an objection to long spans and iron poles. If such conditions are to be met, it is purely a matter of introducing suitable data in the calculations, and to give the wires such a sag that the strain will not reach the limit of elastic deformation in the coldest weather and with the maximum overload put on by the wind and the snow, and to proportion the poles in accordance. Only by suitable calculations can one be sure of arriving at a solid construction, and where difficulties are great, the recourse to sound engineering, which does not halt at severe conditions, is justified.

As to wooden poles, I quite agree that, if in any country they can have a considerable life, this would be an argument in their favor. The life of wooden poles differs very much according to locality; on mountains they will last very long, in cultivated plains they will have a very short life. The fact that the average life of wooden poles is longer in America than in Europe, may perhaps depend on the fact that in America the most important transmission lines run through mountainous country, while in Europe a large number of such lines, after passing through valleys, come out on cultivated plains where irrigation is extensively practiced.

On the other hand, I do not think there is any danger from rusting of iron poles. Rusting is prevented by repainting, and it may be observed that no bridge has ever been known to break down through the action of rust.

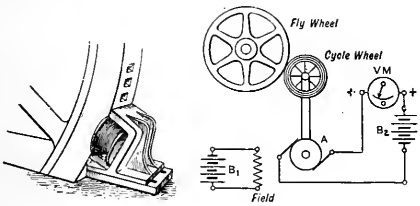
The editorial emphasizes the use of cross arms to prevent trouble from insulators breaking, and I may say that by the use of good modern insulators, the occurrence of such inconveniences is quite insignificant; and the use of cross arms as suggested in order to prevent the consequences of accidents which in practice very seldom occurs, detracts from the many mechanical advantages of metallic construction.

MILAN, ITALY. GUIDO SEMENZA.

DIGEST OF CURRENT ELECTRICAL LITERATURE.

DYNAMOS, MOTORS AND TRANSFORMERS.

Alternators in Parallel and the Coefficient of Speed Variation.—BOHLE.—The conclusion of his long paper on this subject. He deals with the operation of a synchronous generator in parallel with a non-synchronous generator and then discusses the connection in parallel of alternators driven by gas engines. The difficulties are here great on account of the great speed variation and because the coefficient of speed variation varies according to the load. The latter difficulty may be overcome by loading an incoming machine artificially. Dettmar uses for this purpose a Foucalt brake which acts on the fly-wheel as shown in Fig. 1. The magnet is excited by direct



FIGS. 1 AND 2.—ALTERNATORS IN PARALLEL.

current, the load being regulated by means of a regulating resistance. The heat produced by these currents is kept low by the air currents, especially as the proceedings last only a short time. On account of the artificial load, the regulator of the engine has a position which corresponds to the load, so that the machine will take over part of the load of the other machine immediately. The faucault brake acts at the same time as a damper, diminishing the mechanical fluctuations. The author then discusses the various methods for determining the coefficient of speed variation. Electrical methods are the only accurate ones and even these cannot be relied upon, when the coefficient of speed variation is less than 1/200. Fig. 2 represents a method of the General Electric Company. A cycle wheel is fixed on the shaft of the small direct-current generator. The rubber tire is braced against the fly-wheel of the engine and the excitation of this generator is such that its e.m.f., corresponding to the mean speed, is equal and opposed to the pressure of a battery, B_2. Between the armature of the generator, A, and the battery, B_2, is joined a Weston voltmeter with a low-reading scale. It will be evident that, if the fly-wheel rotated at a uniform speed, equal to the mean, the voltmeter would show no reading; but as the fly-wheel is rotating with a varying speed within a revolution, the voltmeter needle will oscillate, the amplitudes from the zero position being a measure of the variation of speed. A modification of this method by Franke is shown in Fig. 3. The armature, A, and the indicator, I, are coupled to the engine, the indicator closing the circuit once in a revolution at a definite crank position, causing a deflection on the galvanometer, G, which is proportional to the instantaneous pressure at this instant, hence also to the corresponding annular velocity. By bringing the brushes of the indicator into different positions the circuit will be closed at a different time. This method would be very accurate, if the time of a revolution would not change, but on account of this the instantaneous velocity changes with each revolution, so that the pressures for the same brush position are not constant at different times. To avoid this fault, the arrangement of Fig. 4 may be employed, in which the influence of the changeable time is considered. Here the pressure of the armature, A, is closed by the high resistances, R_1 and R_2. There are thus two circuits. On account of the drop in R_1 the back pressure, E_1 (at the instant the circuit is closed) is compensated, say, by means of the galvanometer, G_1. The pressure, E_2, is compensated similarly by G_2, which should possess a periodic damping and a fairly large periodic time. Galvanometer G_2 shows, therefore, only changes in the number of revolutions, or, in other words, the changes in the time of a revolution. Observations must be made in circuit I at the time when the galvanometer, G_2, shows no deflection, all observations will then correspond to the same time. It is seen that two persons are required for the experiment, which requires a great deal of time and patience. Irregularities in the pressure due to the construction of the experimental generator, must, of course, also be eliminated beforehand. Very small coefficients, that is to say, those below 1/200, cannot be determined. The author describes briefly the use of phase lamps, etc., and finally describes an

apparatus of Goerges for demonstrating the oscillations of parallel running alternators.—Lond. *Elec.*, May 6.

Compounding of Single Machines Supplying a Three-Wire System.—ROSENBERG.—If a single direct-current machine for supplying a three-wire network is to be compounded, the series winding is generally placed in the two outers, I_1 and I_2, as indicated in Fig. 5 by the coils, H_1 and H_2. But this division of the series winding is not always possible. The author shows that the arrangement of Fig. 6 is equivalent. Here the coil, H, is inserted in one outer, and the coil, h, in the neutral, while the second outer has no excitater winding. Fig. 6 shows the arrangement of Debrowolsky, where the neutral wire is connected to the central point of an induction coil, T, the two

terminals of which are connected to two slip rings on two diametrically opposite points of the armature. The number of turns of h must be one-half of H. The cross-section of the winding, h, is to be determined according to to the value of the differential current, which it has to carry.—*Zeit. f. Elek.* (Vienna), May 1.
